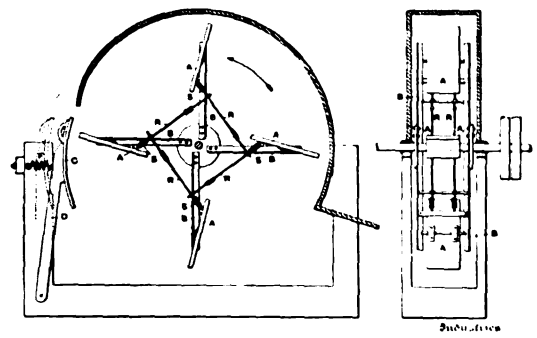
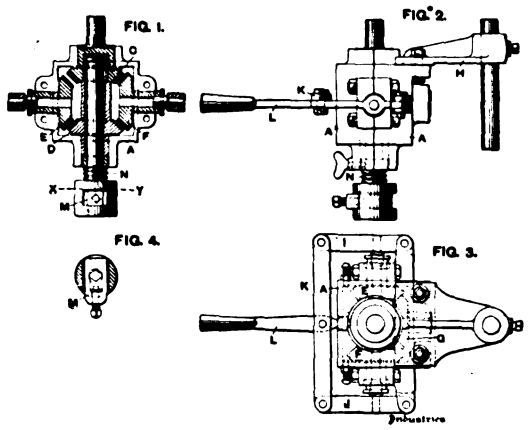
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.



ENGINEERING.

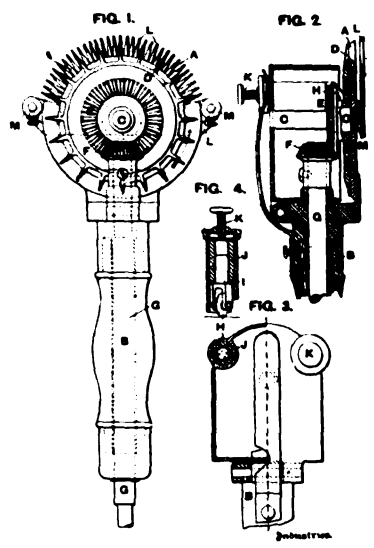
Bush for Shafting.—*L. W. Thomas, Dover.*—The bush is designed for securing pulleys to shafting, &c. The bush is composed of two eccentric collars, which are halved. The collars are made to fit one within the other, and the inner surface of the smaller collar to fit the shaft to which it is applied. The halves of each collar are reversed, so that the thin edge of one half faces the stout edge of the other half. The stout parts of the outer collar overlap the thin parts of the inner collar, so that the outer surface of the whole, when placed upon the shafting, is concentric with the shafting. From the above description it may be seen that by sliding in a rotary direction the halves of the outer collar over the halves of the inner, the bush is radially increased or decreased according to the direction turned, yet the outer surface of the whole always remains concentric to the shafting. The pulley to be secured is bored to pass loosely over the shafting. The bush in its closed condition is inserted in the annular space between the bore of the wheel and the shaft. It is then expanded by sliding the outer halves over the inner until the pulley is tightly secured. The work upon the pulley tends to expand the bush and hold the pulley much tighter. Claims: (1) An improved bush for shafting or spindles, consisting of an inner and an outer eccentric wedge bush, each made in halves, and which are so combined concentrically when applied to a hole in a pulley, wheel, coupling, or other article, that the revolution of the pulley, wheel, coupling, or other article causes the outer pair of half bushes to turn upon the inner pair, thereby tightening up the bush upon the shaft or spindle; (2) refers to the bushes as illustrated in the specification.—No. 6679. April 18th, 1889,

Damping Warps in Looms.—*J. Lord, Todmorden, Yorkshire.*—The apparatus here described permits an easy regulation of the damping according to the varying state of humidity of the atmosphere, and enables the weaver to stop the action of the apparatus without having to remove it from the loom. It consists of a trough suspended by handles underneath the warp bearer, over which the warp passes at the back of the loom. In the trough is a roll made of perforated sheet metal, such as zinc or tinned copper. The roller is pivoted to the ends of the trough, one of the pivots being square part of its length, and resting in a square hole. The roller has a sufficient play longitudinally to permit the square or round part of its pivot being pushed into the square hole, and thus hold the roller stationary or permit it to revolve. Other ordinarily used means for fixing a roller in its position and releasing it for the purpose of turning it round may be used instead of that described. A piece of cloth is attached to the roller and hangs over the edge of the trough, and has attached at its end a rod, roller, or brush. The trough is filled with water through a suitable funnel at one end, and the cloth, after being wound on the roller and thoroughly wetted, is unwound till it rests upon the side of the warp beam and damps the warp as it is unwound. The water taken from the cloth is replaced from the trough by capillary action. By turning the perforated roller, a greater or shorter length of contact between the cloth and warp, and consequent variation of the dampness of the latter, is attained; while by winding the cloth on to the roller till the rod, roller, or brush at the end of the cloth is stopped upon the edge of the trough, the damping can be entirely stopped. Claim: The arrangement of trough, perforated roller, with locking device and cloth attached to the same, as described.—No. 10600. July 1st, 1889. 6*d*.



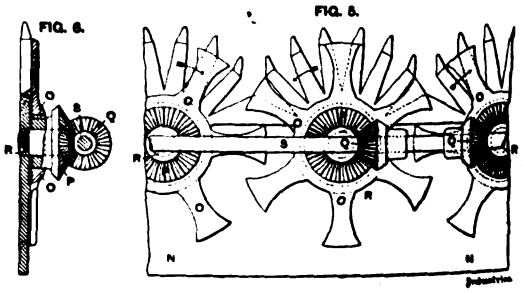
Machines for Scutching Flax.—*R. H. Hayward, Crewkerne, Somersetshire.*—The machine is designed for scutching flax and other fibrous material. The improvements consist of a spring striking board and spring feed board arranged to be fed by hand. The illustrations show Fig. 1 a side elevation of the scutching machine, and Fig. 2 an end elevation of the same. To the back of the "strikers" A are connected the springs S for giving elasticity to the blows of the strikers. These springs are attached to rods R, which connect them to the rigid arms B. The rods R are adjustable to regulate the tension upon the springs. The feed board C is supported upon arms D, which are pivoted to the frame of the machine. A spring F serves to draw the feed board back, and retain it in its normal position shown by dotted lines. The feed takes place over the top edge of the feed board, and is regulated by the operator pressing in the board by his knee or hand. The arms B carrying the "strikers" are revolved in the direction of the arrow by suitable means such as shown. The machine is cased in, and, by the motion of the "strikers," causes a current of air, which tends to keep the

FIG. 1. FIG. 2.



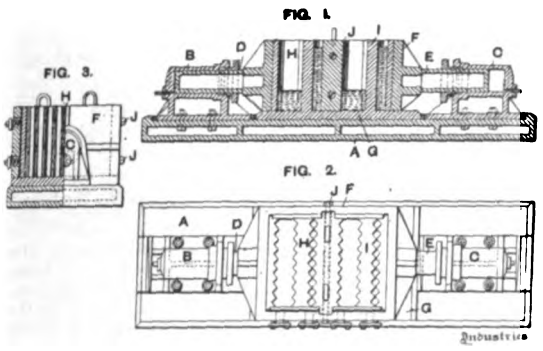
fibres straight and carry off dust and skimp. Claims: (1) In a machine for scutching flax or the like fibrous material the combination with a spring feed board such as C of spring strikers such as A so as to give elasticity to the force of the blow delivered by the latter substantially in the manner and for the purposes hereinbefore described and illustrated; (2) in a machine for scutching flax or the like fibrous materials the application of a spring or springs to the "striker" ("swingle" or "sword") so as to allow the latter to "give" according to the resistance offered by the fibrous material being struck—instead of delivering a dead blow as heretofore—substantially as and for the purposes hereinbefore set forth; (3) the movable spring feed board such as C substantially as and for the purposes hereinbefore set forth.—No. 4551. March 15th, 1889. 8*d*.

Tapping Metals.—*J. Miley, Keighley, Yorkshire.*—This specification describes a drilling machine attachment for the purpose of tapping metal holes. Referring to the illustrations, Fig. 1 shows a front sectional elevation of the appliance, Fig. 2 a side view, Fig. 3 a plan, Fig. 4 a section upon the line X Y (Fig. 1). The appliance is inclosed in a square case A, in which are bearings to support the spindles of five mitre wheels C, D, E, F, and G. The mitre wheel C is formed in one piece with its shank, which enters the socket of an ordinary drilling machine mandrel. The spindle wheel G supports the case of the appliance, but the case is prevented from turning with the wheel by a bracket H fixed to the framing of the machine. The lower mitre wheel D is connected by a feather to a mandrel, which carries suitable dies for holding the taps. The wheels E and F are connected to levers I, J, which are coupled together by the link K and the whole operated by the hand-lever L, so that the mitre wheels E and F may be put into or out of gear with the wheel G



as required by the hand-lever L, and thus reverse the motion of the tap mandrel. The last of the wheels G is always in gear with the spindle wheel C, but clears the tap mandrel wheel D. The method of working the machine is as follows: The apparatus being attached to the machine spindle, and the tap fixed in the holder M, the hole to be tapped is brought under the tap and the latter inserted. The machine spindle is then screwed or fed down until the spring N is compressed. The machine spindle may be revolving while brought down, as the tapping spindle is not rotated as long as the reversing handle is not moved, both wheels E and F being out of gear. The handle L is then moved to the side required for driving the tap for tapping, and when the tap has entered the hole far enough its rotation is reversed by shifting the handle to the other side, and the tap screwed out of the hole. Claims: (1) The arrangement or construction of self-contained apparatus for tapping holes in metals attachable to drilling machine and similar spindles substantially as described and illustrated by the drawings; (2) an apparatus attachable to drilling machine and similar spindles for tapping holes in metals containing a bevel wheel C attachable to said spindles and a bevel wheel D with long boss containing a tapping spindle in sliding connection with the same in combination with three other bevel carrier wheels and reversing mechanism so arranged that the wheel D is driven from the wheel C either through one or through two carrier wheels according to the position of the reversing handle; (3) in apparatus for tapping metals arranged as specified in the preceding claim the arrangement of the carrier wheels alternately put into gear with the wheel D and of the reversing mechanism in such a manner that each carrier wheel works itself and remains out of gear with the wheel D unless held in gear by hand by means of the reversing handle as described and illustrated by the drawings.—No. 5320. March 28th, 1889. 8*d*.

Clipping Apparatus.—*A. Muir, Glasgow.*—These improvements, although particularly applicable to appliances for clipping the hair of animals, may be also adapted to reaping and such like machines. The movable cutting part of the clipper is a disc with serrated edge. The movable disc is made to revolve about its axis with its surface in close contact with a second disc, which constitutes the lower cutter. The invention will be more fully understood by reference to the accompanying illustrations. Fig. 1 is a back view with a part removed, Fig. 2 is a sectional side elevation, Figs. 3 and 4 details, and Figs. 5 and 6 the improvements as applied to reaping machines. The stationery cutting disc A is firmly attached to the socket of the handle B. In close contact with A is the movable cutting disc D, which is suitably mounted upon the spindle C, and revolved by mitre wheels E and F. The shaft G of the mitre wheel F is connected



to and driven by a flexible shaft or other suitable means. To keep the movable disc D in close contact with the fixed disc A rollers H are caused to bear upon the back of D. These rollers are pressed forward by helical springs or by india-rubber collars J and washers I (Fig. 4); the pressure, which is a yielding pressure, may be adjusted by the thumb-screw K. In cases where the hair is desired to be cut at special lengths, as, for instance, the human hair, a depth-regulating comb L is attached to the front of the clipper as shown. The comb L is fixed to the clipper by studs, which enter the eyelets M and permit its adjustment at any distance from the front of the clipper. In applying the improvements to reaping machines the front edge of a bed-plate N is formed by casting. This bed-plate extends across the machine, and has upon its top side a series of pins R, which constitute the supporting spindles for the movable cutters

O and their driving wheels P. The wheels P are geared to the wheels Q, which are mounted upon the shaft S driven by gearing connected to the driving wheels of the machine. Claims: (1) In the improvements in apparatus for clipping horses, sheep, and other animals, and which are also applicable to reaping machines and the like, the employment of circular discs having teeth formed on or fixed to them, and which are caused to revolve over the bed-plates or lower cutters, which are also formed with suitable teeth arranged as an arc of a circle, substantially as described and shown in the accompanying drawings; (2) the general arrangement, combination, and construction of the various parts constituting the improvements as applied to clipping horses, sheep, human hair, and such like, all substantially as and for the purposes hereinbefore described and shown in Figs. 1, 2, 3, and 4 of the accompanying drawings; (3) the general arrangement, combination, and construction of the various parts constituting the improvements as applied to reaping and grass-cutting machines and machines of a like nature, all substantially as and for the purposes hereinbefore described and shown in Figs. 5 and 6 of the accompanying drawings.—No. 4775. March 19th, 1889. 8*d*.

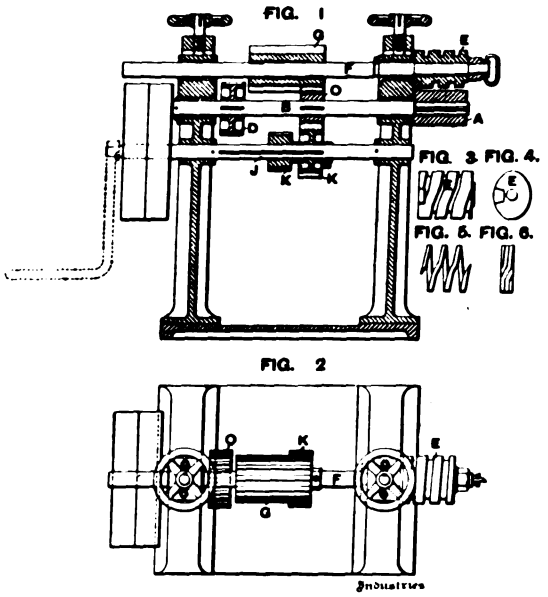
CASTING INGOTS.—*H. Aiken, Homestead, Pennsylvania, U.S.A.*—This method of casting ingots, blooms, slabs, &c., is to facilitate the pouring of the metals direct from large ladles into the moulds, and so reduce loss of time and labour. The apparatus employed in the method consists of a series of moulds, which are capable of being increased in horizontal dimension to permit the metal being poured without difficulty into them from a large ladle, and afterwards the horizontal dimensions may be decreased to reduce the cross-sectional area before the metal sets. Besides decreasing the cross-sectional area, the metal may be divided into a series of sections, which may be readily separated when cold. One form of the apparatus is shown in the accompanying illustrations. Fig. 1 is a sectional elevation, Fig. 2 a plan, and Fig. 3 an end elevation, partly in section. At the ends of a suitable bed A are secured the fluid pressure cylinders B, C, provided with pistons D. E. The pistons D, E are connected to or bear against the ends

of a rectangular frame F. The frame F rests upon a plate G, having partitions H and I, which extend across the frame F and divide it into three receptacles. The frame F is also provided with a partition J which subdivides the central space into two. All the partitions have serrated faces, and it will be seen from the drawings that by shifting the frame F to the left or to the right, two of the spaces are enlarged in cross-sectional area and two reduced. In working the apparatus the metal is poured into the enlarged spaces, and the frame F shifted to the right or left, as the case may be, to reduce the sectional area. When the metal has set in these first two spaces, metal is poured into the others and the solidified metal in the shape of ingots removed from the first. The frame F is shifted to the right or the left by admitting the working fluid to one of the cylinders. Ten claims are made.—No. 19890. February 1st, 1889. 8*d*.

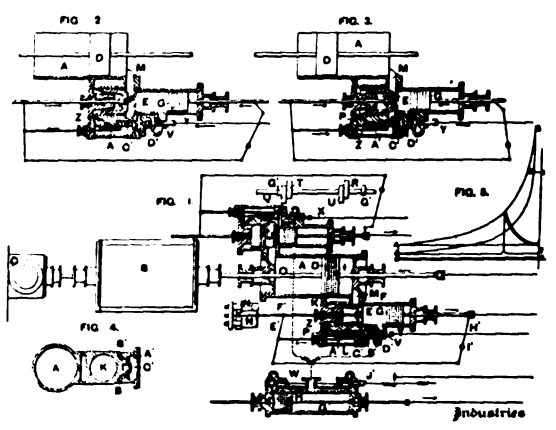


EMPLOYMENT OF GAS ENGINES FOR LOCOMOTION.—*E. F. Piers, Manchester.*—The difficulty attendant upon the employment of gas or petroleum engines for locomotive work is the want of means for readily starting them. In this invention the engine is kept continually running, and by a system of pumps has its power utilised for propulsion as desired. A method of carrying out the invention is shown in the illustration. B is the crank shaft of the gas motor A. To the shaft B is fixed the eccentric C, whose rod D is pivoted to the end of a lever E having its other end pivoted to a lever F. The lever F is supported by the shaft B, and its position adjusted by the hand lever T. U are pumps whose pistons are connected by the rod G having a block H through which the lever E slides. When the vehicle is in motion and the engine at work, the motion of the eccentric works the pumps, and draws water from the tank V up the suction pipes J into the pumps. The water is then forced by the pumps along the pipes I to a motor cylinder K, whose piston is connected to the crank of an axle shaft M, and thus drives the vehicle. When the vehicle is at rest the engines and pumps are still kept at work, but the water as it is forced from the pumps instead of passing through the motor cylinder K is returned by the cock P through

the pipe S to the tank. The stroke of the pumps is varied as desired by the hand lever T and the cock P is controlled by the rod R. Claims: (1) For working tramcars and other vehicles, or other machinery requiring to be frequently stopped and started, the combination of a gas engine, petroleum engine, or the like, a force pump or force pumps, worked by the said engine for forcing motive fluid into a second engine connected with and for giving motion to the driving mechanism of the car or other machine as described; (2) the combination of a gas engine or the like a force pump or force pumps operated thereby for forcing motive fluid into a second engine the passage from the pump or pumps to the second engine, being provided with a valve or valves by means of which the motive fluid may be directed into or cut off from the second engine as required as and for the purpose described; (3) the means for working the force pump or force pumps from the crank shaft of the gas or like engine and for regulating the strokes of the pump or pumps as and for the purpose described.—No. 2144. February 6th, 1889. 8*d*.

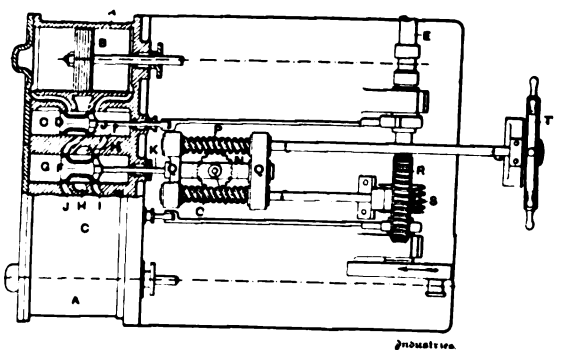
STEAM BOILERS.—*M. Hutchison, Cambuslang, Lanarkshire.*—This refers to a feed-water heating appliance in which the water is heated by live steam within the boiler without the feed water and steam mixing. It also circulates the water in the boiler. According to one arrangement of this invention a closed feed-water chamber is fitted to extend across and high up in the steam space of the boiler. At the ends of this chamber is fitted or connected tube plates carrying a series of tubes extending from end to end of this chamber. Over the tube plates are fitted pocket chambers or separators, into which the steam of the boiler enters and passes into and heats the tubes. The feed water is passed into the tube chamber and circulates outside the tubes, thus becoming heated by the steam within the tubes. The feed water as it becomes heated passes down vertical pipes to a horizontal perforated pipe at the bottom of the boiler and is distributed in the water of the boiler. Another arrangement is to surround the tubes with the steam in the boiler, and pass the feed water through the tubes. The ends of the tubes are enclosed in small chambers, to one of which the feed water is supplied, and then passed through the tubes to the other chamber, and from there to the distributing pipe already explained. Three claims are made.—No. 6820. April 23rd, 1889. 8*d*.

MANUFACTURE OF CHAINS.—*A. G. D. Crawshay, London.*—The chain is constructed, according to this invention, in such a manner that the strength of each link is rendered in a great measure independent of the weld. Instead of forming the link by one coil of rod of the finished thickness of the link, as is usual, the link is formed out of several coils of rod of less thickness than the finished link, and the coils welded together side by side to form the link. The machine for constructing these chains is shown in the accompanying illustrations. Fig. 1 is a sectional side elevation, Fig. 2 a plan, Figs. 3 and 4 are details, Figs. 5 and 6 show the different forms of the link in construction. The machine shown produces the link in the form shown in Fig. 5. Its convolutions are afterwards closed, as shown in Fig. 6, and then welded together between suitable dies. In the machine, A is the mandrel upon which the rod is wound. The rod is guided in its convolution around the mandrel A by a spirally grooved and rotating mandrel E. The mandrels A and E are of an elliptical cross section. They are attached to the shafts B and F, which are geared together, and to the driving shaft J by the toothed wheels G, O, and K. The toothed wheel K is made to slide upon the shaft J, and is connected to a second toothed wheel, which may be put into gear with the wheel D to reduce the speed of the shafts F B relative to the driving shaft J. The groove in the mandrel E is not truly helical, but has a por-



tion of quicker pitch in each turn, to form a set off or joggle in each convolution of the link and in line with the scarfed ends of the link. The bar to be operated upon, having its ends tapered off or scarfed, is fixed by one end to the mandrel A. The mandrels are then revolved, and the bar wound upon the lower mandrel A. guided by the groove in E, to take the shape as shown in Fig. 5. The link so formed is passed in the manner of a split ring upon the last link of the chain being formed, and the convolutions are welded together by dies that operate upon half the link at a time. Claims: (1) The herein described process of manufacturing chains by first coiling a bar of metal helically with joggles to suit the scarfs of the ends and with the convolutions separated, then engaging with the coil a link previously made, flattening the coil, and finally shaping the link by suitable tools or dies; (2) for coiling a bar to form a link in the manner above referred to, the machine substantially as herein described with reference to Figs. 1 to 4 inclusive.—No. 3127. February 21st, 1889. 8*d*.

PROPELLING VESSELS.—*W. Blair, Paisley, Renfrewshire.*—A circular frame with floats at its circumference, in construction similar to a paddle wheel, is attached to the ship at its stern. The wheel is supported with its axis vertical, and it is wholly immersed in the water. Its shaft is geared by bevelled or mitre wheels to the propeller shaft of the ship's engines. A second and similarly constructed wheel may be fixed to the propeller shaft with its axis horizontal. The floats on the wheels are so constructed that by the rotation of the wheels upon their axes, the resistance of the water against the motion of the floats propels the vessel. Claim: The use of a paddle-like circular frame wholly immersed in water in connection with the shafts, wheels, &c., as described.—No. 5535. April 1st, 1889. 6*d*.



MACHINERY FOR ROLLING METAL.—*H. & D. E. Jones, Neath.*—In this invention use is made of inclined or wedge-shaped blocks instead of the usual set screws and accessories for pressing down the riders which hold down the top roll. The upper cross part of the frame standards are constructed with an under flat face for one side of a wedge block to bear against. The under side of this block is made inclined, and presses upon the top of the rider, which is also inclined to correspond to the incline of the block, but set in opposite directions. The wedge-shaped blocks are connected by metal straps to a screwed rod, which passes through the screwed boss of a hand wheel. By turning the hand wheel the wedge-shaped block can be shifted and so force the top roller down. One claim is made.—No. 351. January 8th, 1890. 6*d*.

STEAM ENGINES.—*G. Schimming, Berlin.*—The inventor overcomes the difficulties attendant upon the use of superheated steam by superheating it in the cylinder itself. This is done by mixing with the steam an exploded mixture of hydrocarbon and air. Fig. 1 is a horizontal section through the apparatus; Figs. 2 and 3, similar sections through one explosive cylinder; Fig. 4, a cross section through the high-pressure steam cylinder, &c.; and Fig. 5, indicator diagrams. A is the high-pressure cylinder, and D its piston; B the low-pressure cylinder, and C the air pump. Upon the high-pressure cylinder A are situated the explosion cylinders E and J, having pistons G and separated from the steam cylinder by piston valves F. Steam is admitted from the boilers to the high-pressure cylinder A by the valves I and O, the valves opening at the commencement of the piston stroke and closing when it has completed one-fifth of its stroke. The explosive chambers are filled with a mixture of air and gas in the following manner. The piston H draws gas and air into the gas compressor cylinder through the slide valve W, and upon the return stroke passes out at the same valve to the explosion chamber.

The action of the engine is as follows:—The explosive mixture is passed from the compressor to the explosion chamber E, and there exploded. By the force of the explosion the piston F is driven back and the heated charge admitted and mixed with a charge of steam in the cylinder A. The back of the piston F is in communication with the steam in the boiler, so that as the force of the exploded charge lessens the valve F closes. At the end of the stroke the same cycle of operations is repeated by the explosion cylinder J. Claims: (1) The method of superheating the steam for operating prime movers by the introduction of inflammable gases or other inflammable substances suitably mixed with air into explosion chambers, igniting such mixture in said explosion chambers and mingling the products of the explosion of said mixture with the steam serving to operate such prime movers; (2) in an apparatus for superheating steam and applying the same to steam engines, the automatic valve for opening and closing the communication between steam and explosion cylinders; (3) the improved apparatus for superheating steam and applying the same to steam engines.—No. 4796. March 19th, 1889. 8*d*.

STEAM STEERING GEAR.—*W. H. Harfield, London.*—This invention refers to the valve gear of the engines used for steering ships. In the accompanying illustration is shown the plan of an engine fitted with valve gear in accordance with this invention. The admission of steam to the steam chests C, and thus to the cylinders A, is controlled by the central valve F. The valve F is connected to a slide, which carries a toothed wheel N, geared to two screws O, P. The screw P can be revolved by the steering wheel T, and the screw O is revolved by the motion of the crank shaft E transferred through the worm gearing R, S. The

operation of the gear is as follows:—Suppose that the steering wheel is turned in the direction of the arrows, the worm P is revolved and causes the wheel N to turn upon its stud and roll upon the other worm towards the right. The slide and the valve F are thus moved to the right, opening the ports I and admitting steam to the cylinders. The worm gearing R, S then revolves the screw O in the direction of the arrow and returns the valve to its normal position. The engine works concurrently with the movements of the steerman, that is to say, if the steerman's action is quick, the volume of steam admitted to the cylinder is sufficient to rapidly work the gear and *vice versa*. Claims: (1) In engines for use in steering ships the combination of two worms or screws with a worm wheel for exerting a counteracting effect upon a valve which controls the admission of steam to the cylinders; (2) the manufacture and use of steering gear, the engines of which are provided with the improved mechanism described and illustrated.—No. 5018. March 22nd, 1889. 8*d*.

CUTTING METAL BARS.—*C. J. Westwood, London.*—A form of shearing machine is here described for cutting bars of irregular section, such as tee, channel, and bulb bars. The knives of this machine are partly shaped to the cross section of the bars, so that when the two knives are placed together and opened they form an aperture of approximately the shape and size of a cross-

Digitized by Google

section of the bar to be cut. The bar to be cut is passed into this aperture, and the knives closed upon each other by hydraulic, steam, or other suitable power. Claims: (1) In means for cutting or cropping metal bars of irregular sections, making the shearing edges of the stationary and of the movable blocks with a cut-away portion, or piercing, or aperture, which, when the opposing shearing edges are brought opposite to each other, will together form cutting edges providing an aperture into which the metal bars to be cut are to be inserted, and will thereby be supported whilst the cutting or cropping will proceed as and for the purpose set forth; (2) the means for cutting or cropping metal bars constructed and operating as set forth.—No. 13,015. August 17th, 1889. 8*d*.

RATCHET BRACES.—*T. Bass, London.*—This is a double-acting ratchet brace, in which the operation is continuous by the movement of one handle only. The brace is provided with two handles or levers, one being held stationary whilst the other is made to work the brace. The stationary handle is rigidly connected to a frame supported upon the spindle of the brace. The movable lever is pivoted to the same frame, and has two arms projecting approximately at right angles to its length from its point of attachment. To the ends of these arms are pivoted two spring pawls, which engage in the teeth of the ratchet. By this construction the pawls engage alternately with and revolve the ratchet, as the lever is moved to and fro upon its pivot, and the frame is held stationary by the other lever or handle. Claim: The manufacture and use of the improved ratchet brace hereinbefore described.—No. 4196. March 9th, 1889. 6*d*.

ELECTRICITY.

METERING ELECTRIC ENERGY.—*W. H. Scott and Laurence, Paris, & Scott, Limited, Norwich.*—This meter mainly consists of a heavy timing pendulum, which makes and breaks periodically the electric current actuating the metering part proper, and of a coiled conductor suspended upon a frame and oscillated in the manner of a pendulum by the action of an electromagnet. By the oscillation of the conductor coil the indicator wheels are driven. In the accompanying illustration Fig. 1 is a front view, Fig. 2 a side view, and Fig. 3 a plan of the appliance. The heavy timing pendulum G is suspended upon an iron rod F in close proximity

FIG. 2.

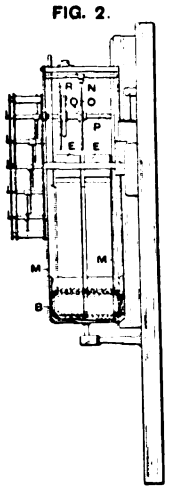


FIG. 1.

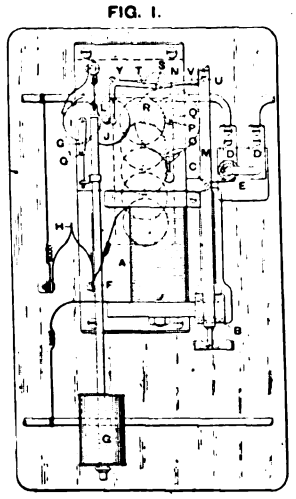

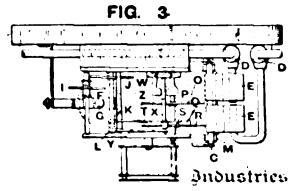

FIG. 3.

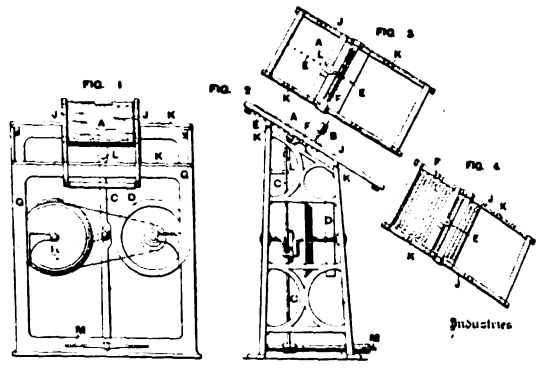
Industries

to the poles of an electromagnet A. The electromagnet A is in a shunt circuit to the mains. By the oscillation of the pendulum the shunt circuit of the magnet is broken at the spring contacts H, and its motion is communicated by a pawl and lever G^2 to a ratchet wheel I. The ratchet wheel I is geared to the wheel J, whose axle supports a cam L. The coiled conductor B is suspended upon the frame M and electrically connected to the top main by the flexible copper strips E. Close to its point of suspension the frame M carries a pawl V engaging with the teeth of a fine ratchet wheel O. This ratchet wheel O is fixed to the same spindle as the coil spring Q whose other end is attached to the toothed wheel R. The wheel R is loose upon its spindle, but held stationary normally by the catch S. The action of the appliance is as follows:—On a current passing through the mains the electromagnet becomes vitalised and the pendulum is attracted to it. The contacts H are thus broken and the pendulum is released and oscillates. The vitalisation of the magnet also attracts the coiled conductor, and causes it to partially rotate the ratchet wheel O, wind up the spring Q, and drive the indicator wheels. By the make and break movement of the pendulum, this action continues until the coiled spring is so tightly wound that its resistance to further winding equilibrates the attractive force of the magnet, which varies as the current in the mains. The pendulum, however, still continues to beat, and the cam L revolves and coming into contact with bell crank lever Y lifts the catch S out of the wheel R, and permits the spring Q to uncoil. When the cam has passed the bell cranked lever, the catch falls into the toothed wheel again, and the above-described action is repeated, the motion of the coiled conductor winding up the spring and driving the indicator wheels. Claims: (1) In combination with electric meters a wattmeter or electro dynamo meter arrangement, in which the force produced being proportional to the current flowing in the series coil or to the watts between terminals is caused to wind up a ratchet wheel against the force of a coiled spring, the other end of which spring is fastened to a toothed wheel which is free on the same spindle, so that the spring can be periodically let down and locked again in any position it may take up; (2) the arrangement and combination of parts constituting the apparatus for metering electric currents substantially as hereinbefore described and illustrated in Figures 1 to 3 of the accompanying drawings; and (3) constituting a modification.—No. 3402. February 26th, 1889. 8*d*.

HOLDERS FOR INCANDESCENT LAMPS.—*P. A. Newton, London.* (*A. Swan, U.S.A.*)—The holder is composed of insulating material, such as papier maché, moulded preferably to the form of a truncated cone. The base of the cone is recessed to receive the base of the lamp through which pass the insulated wires leading from the carbon filament to insulated contact plates on its surface. The holder is pierced with ducts or passages for the leading wires from the mains. In some cases the leading wires lie in the recess of the truncated cone, and constitutes, with the plates upon the surface of the lamp base, the means of connection between the lamp filament and the mains when the base of the lamp is screwed into the recess of the cone. Should it be desired to provide a switch for putting out the lamp, a spring contact can be arranged in connection with one terminal operated by a key. The holder is finished off with a metallic cap piece screwed thereto, which may more or less fully envelop the holder. In pendant lamps the electric cable may pass through a hole in the summit of the cap piece, and, being knotted below, support the lamp. A suitable shade for the light is attached to the lower part of the socket. Nineteen claims are made for this lamp-holder.—No. 5066. March 23rd, 1889. 8*d*.

INCANDESCENT ELECTRIC LAMPS.—*J. W. Edmundson, Gateshead-on-Tyne.*—As is well known, the surface of a carbon conductor forming the illuminating part of an incandescent electric lamp becomes gradually disintegrated by use, and the carbon thus detached settles upon and blackens the glass of the lamp. In order to remedy this defect the inventor prepares carbon conductors by coating them with a metallic deposit. A suitable metal for the purpose is chromium, as its fusing point is very high. Chromium combines with the carbon of the conductor, forming a highly conductive hard surface; it fills up the pores and produces a smooth grey surface not liable to disintegration. The deposit may be produced by painting the surface of the carbon with a solution of chromium chloride, the chromium chloride being dissolved in spirits of wine. After painting the carbon is warmed by passing a current of electricity through it, or by placing it in an oven, until the coating is quite dry. The carbon is then enclosed in a vessel, from which the air is removed, and a current of electricity passed through, heating the carbon to incandescence. The coating upon the carbon is thus decomposed, and the chlorine passing off, the chromium is absorbed by the carbon. This may be repeated until the required coating is obtained. Claims: (1) For an incandescent electric lamp, a carbon conductor coated with a metallic deposit; (2) coating carbon conductors for incandescent electric lamps with chromium in the manner described.—No. 3363. February 25th, 1889. 4*d*.

ELECTRIC INDICATORS.—*B. C. C. Cant, Walthamstow, Essex.*—The instrument is usually termed an electric mechanical throw-back or annunciator. It is joined in circuit with an electric bell and push; the electric current, passing through two magnets, sets free a flag made of brass or other suitable material, by the attraction of an armature. The improvement consists of a new form of armature. The armature has on one side a small lug, which engages with a lug upon the signal or flag, and holds the signal up. When the magnet is vitalised the armature is attracted by it, and the lug upon the armature is withdrawn from under the lug upon the signal, letting it drop and indicate the circuit made. Any suitable mechanical means may be provided to replace the flag after indication. One claim is made.—No. 7600. May 7th, 1889. 6*d*.



CHEMISTRY.

GREEN AND VIOLET COLOURING MATTERS.—*C. D. Abel, London.* (*The Actiengesellschaft für Anilenfabrikation, Berlin.*)—These colouring matters are manufactured by first treating methylbenzyle-aniline and ethylbenzyle-aniline with sulphuric acid monochlorhydrine, or fuming sulphuric acid, and so obtaining sulphuric acids of these bases. These acids are readily condensed with aromatic aldehydes forming leuco-sulphonic acids, which by oxidation are converted into green and violet colouring matters. Claims: (1) The production of methylbenzyle-aniline-sulphonic acid and ethylbenzyle-aniline-sulphonic acid by sulphuration of methylbenzyle-aniline and ethylbenzyle-aniline with fuming sulphuric acid and sulphuric acid-monochlorhydrine; (2) the production of leuco-sulphonic acids by condensation of the sulphonic acids of methyl and ethyl benzyle-aniline with aromatic aldehydes; (3) the conversion of the leuco-sulphonic acids, referred to in claim (2), by oxidation into green and violet colouring matters.—No. 7550. May 6, 1889. 6*d*.

WHITE LEAD.—*R. W. E. MacIvor, London; A. Darlington, London; G. Paul, Edinburgh; & J. Allan, London.*—These improvements are based upon those described in a previous specification, No. 10426 of 1888. In the present invention the white lead, or carbonate of lead, is produced by first treating oxide of lead—that is to say, litharge or massicot—with a solution of acetate of ammonia, whereby the oxide of lead is transformed into hydrate of lead, and then converting this into carbonate of lead by the injection of carbonic acid. The hydrate of lead readily unites with carbonic acid to yield the final product of carbonate of lead. The rapidity with which the oxide of lead is converted into hydrate depends upon the strength of the acetate of ammonia solution—the weaker the solution the slower the convertion; a strength between 5 per cent. and 25 per cent. may be used with advantage. The carbonic acid is introduced into the mass of hydroxide of lead formed by the oxide of lead and acetate of ammonia, either by a series of concentric rings perforated with small holes in the bottom of the vat or by passing the carbonic acid down a hollow shaft to which are attached stirrers, and through perforated tubes attached to the stirrers. Claims: (1) The improvements in the production of white lead or carbonate of lead, consisting in the treatment of oxide of lead—that is to say, litharge or massicot—with a solution of acetate of ammonia in a closed vessel, the contents being agitated by a mechanical stirrer whilst carbonic acid gas is admitted by pipes arranged as described; (2) the improvements in the production of white lead or carbonate of lead, consisting in the treatment of oxide of lead—that is to say, litharge or massicot—by agitation with a solution of acetate of ammonia in a closed vessel connected with a cistern charged with acetic acid, whereby any free ammonia carried over during the operation may be absorbed, carbonic acid gas being also supplied to the vessel; (3) the process as described for the production of white lead or carbonate of lead from oxide of lead—that is to say, litharge or massicot—by treating the same in a closed vessel with a solution of acetate of ammonia of suitable strength as set forth.—No. 6815. April 23rd, 1889. 8*d*.

MISCELLANEOUS.

SOUND RECORDING APPARATUS.—*J. Gale, London.*—In phonographs, graphophones, and such like sound recorders, use is usually made of cylinders covered with tinfoil or wax for receiving, as the cylinders revolve, the impressions made by the scribers. By the present invention the cylinder is replaced by a flat surface, which is made to oscillate and move downwards at regular intervals by the mechanism shown in the accompanying illustrations. Fig. 1 is a front elevation of the apparatus, Fig. 2 a side elevation, Fig. 3 an under view, and Fig. 4 an under view of a modification. A is the tablet forming the recording or receiving medium, and it is preferably of rectangular shape. The tablet is mounted upon a frame J, which is capable of being slidden longitudinally on V-shaped guides K by the rocking lever C attached to the frame J at L. The lever C is rocked by the treadle M, and its motion is steadied by the fly wheel D, which receives motion from the rocking lever C in a manner that may be readily understood from the illustrations. The downward movement of the tablet A at the end of each stroke is caused by the pins E attached to it running in the guides F. The guides F are stationary, and connected to the framing G. A modification of these guides is shown in Fig. 4; there the guides are attached to the back of A, and a single pin E is fixed to the framing G of the machine. The usual mouthpieces, disc needles, cutters, &c., used in sound-recording instruments are used in combination

with the above-described machine. From the motion of the tablet A it may be seen that the impressions made by the scriber B upon it will be in parallel lines, and proceeding from the top downwards. Claims: (1) In instruments and apparatus for recording and repeating speech and other sounds the recording or receiving tablet A having a plain flat surface and receiving longitudinal and transverse motions substantially as set forth; (2) in instruments and apparatus for recording and repeating speech and other sounds the tablet A, the frame J sliding in guides K, the grooves or slots F and pins E, together with mechanism for reciprocating the frame A substantially as set forth; (3) in instruments and apparatus for recording and repeating speech and other sounds the combination with the receiving or recording tablet A, having a plain flat surface, of the mechanism for giving motion to same as described and illustrated.—No. 5507. March 30th, 1889. 8*d*.

INDICATING THE PRESENCE OF FIRE-DAMP.—*J. Pitkin, London, & J. T. Niblett, Greenwich.*—A small instrument is described in this specification for use in mines to indicate the presence of fire-damp, or in gas mains to indicate the escape of gas. The invention is based upon the property certain metals have of evolving heat in the presence of hydrogen gas. One of these metals is spongy platinum or platinum black. The instrument consists of a thermometer to which platinum black is applied in such a manner that if the instrument be taken into the presence of fire-damp the increased temperature of the platinum black will at once be indicated by the thermometer. Two thermometers are preferably placed side by side and the bulb of one covered with the platinum black, so that the difference of temperature due to the presence of fire-damp may be readily seen. The platinum black is applied in a pasty condition and held in place by a covering of silk ribbon or thread. Claims: (1) The treatment of thermometers as above described with metallic substances, having the property of evolving heat in the presence of hydrogen gas or its gaseous compounds, overlaid with a covering of fibrous material, such as silk; (2) the construction and arrangement of instruments for indicating the presence of hydrogen gas or its gaseous compounds as described.—No. 4629. March 16th, 1889. 8d.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

THE INSTITUTION OF NAVAL ARCHITECTS.

(*Continued from page* 304.)

Mr. W. H. White then proceeded with the fourth section of his paper, "Notes on Recent Naval Manœuvres."

It is very much the fashion, he said, to criticise adversely the steaming powers of warships, and to contrast them unfavourably with those of mercantile vessels. This is done without reference to the essential differences between the services that have to be performed by war and merchant ships, or recognition of the inherent difficulties attaching to warship propulsion. A merchant ship is built and engined for the purpose of steaming continuously at certain maximum speeds, and to cover certain distances from port to port. Also their regular return to port enables constant attention to be given to desirable repairs or adjustments.

On the other hand, most of a warship's cruising and passages are done at low speeds, requiring only a small proportion of the power she possesses. For example, the "Howe" can be driven at nine knots for less than 1,200 h.p., not *one-sixth* of the power she can develop with natural draught for a few hours. Yet she always has to carry engines and boilers capable of giving her a speed of over 15 knots with natural draught, and over 16½ knots with forced draught. The "waste work" inevitable under circumstances of this kind must be considerable at low cruising speeds, although every effort may be made to diminish it by using only one of the twin-screws or by other devices. In the "Blake" and "Blenheim," with engines of over 13,000 h.p. natural draught, four sets of engines have been adopted, with special disconnecting arrangements, to permit of throwing out the forward sets when cruising at low speeds. In this great range of power and small development under ordinary conditions is to be found, doubtless, the cause of not a few of the difficulties which arise with warship machinery. Such difficulties would disappear if the engines were continuously worked at high speeds like those of merchant ships.

When a warship forms a unit in a fleet the case is still more difficult. Suppose the fleet is ordered to manœuvre at 9 knots. Every commanding officer would be compelled to have command of steam equivalent to a possible margin of speed of 2 to 3 knots, in order to ensure keeping station. In an actual vessel the case might stand as follows:—

9	knots.....	1,000	h.p.	50	revolutions.
11	„	1,800	„	60	„
12¼	„	3,000	„	70	„

In order to secure the ready command of 10 revolutions above the average ordered, 80 per cent. more power is needed to be available whenever ordered; and to have command of 20 revolutions, 200 per cent. margin of power is needed. Standing on the bridge, and taking observations continuously as to his relative position, the commanding officer is frequently obliged to vary the speed of the engines, and the engineer officers have to be ready to obey promptly the constant flow of orders from the deck.

There have been several allegations of *structural weakness* in some of the ships engaged in the manœuvres. For these allegations there is no foundation whatever in any of the reports received. As an example of the loose way in which these statements are made, it may be mentioned that a short time ago an officer from one dockyard was sent to another to take notes of certain small fittings in ships of the "Medea" class, in order that similar fittings might be carried out in the "Medea" and "Medusa." It was immediately announced that he had gone to obtain particulars of structural strengthenings required in consequence of original weakness of construction. This erroneous statement was circulated far and wide; but it had no foundation whatever, as all the vessels of the class have proved to be amply strong, and almost entirely free from vibration, even when developing the full forced draught power.

Experience in these manœuvres has led to alterations, or rather to additions, in certain classes of ships, which may be grouped under three heads:—

(*a*) Additional ventilation has been found desirable, especially to engine and boiler rooms placed under protective decks; this is caused by the increasing pressures of steam, greater powers, and multiplied auxiliary machinery.

(*b*) Greater facilities for intercommunication between engine-rooms and boilers at a low level in the ships have been proved to be absolutely necessary for safety and good working, and are being provided.

(*c*) Improved arrangements for the transport of coal from the upper bunkers to the fires in ships with protective decks, have been shown to be desirable by the hard continuous steaming done during the manœuvres. The principle now adopted is to stow at least half the coal, and often a larger proportion, in bunkers below the protective deck and adjacent to the stoke-holds. For the bunkers above, longitudinal transport has been arranged; so that all the coal can be readily carried where required and dropped into lower bunkers near the fires.

The discussion on the paper was opened by Admiral Mayne, the officer who was alluded to in the paper as having characterised forced draught as "an invention of the evil one." The same opinion was still held by this gentleman, with all the tenacity of which a sailor is capable. It was contended that forced draught acted like a blow pipe on the tube plates, and that no one should make use of the appliance except in an extreme emergency and to save his ship, the risk of breakdown to the boilers being too great.

Sir E. J. Reed was in accord with Mr. White generally on all the points brought forward. Some surprise was expressed by him with regard to the first proposition, on the influence of size and weight upon the seagoing qualities of ships. It was a truism to say that the big ship must be the best for withstanding heavy seas. To know also that any change had taken place recently from small vessels to large ones in the Navy came as news to him. If some of the ships built while the construction of our national fleet was in his hands were small, this was because they were wholly protected by armour. While not being aware that large ships

200-TON HYDRAULIC RIVETING PLANT.

Designed and Constructed by Messrs. Anderson & Gallwey

behaved better than small ones, he was glad to know that the days of the longer vessels were not numbered. This was referred to because the Board, when introducing the "Nile" and "Trafalgar" designs, described them as the last of their type. There could be no doubt, however, that Mr. White's new ships would be the best in the Navy. When considering the "Medea" class of ships, the experience gained in the past did not appear to have been taken into account by the Department. These vessels were low in the waist, and not covered in from end to end, yet he was responsible for two fast cruisers built in the same way, and they had been shown to be undesirable. As to measured mile trials, it was absolutely necessary to have a standard of comparison between ships, and all the conditions of weather, stoking, &c., could only be obtained in this way. Sea-going trials did not furnish this test between ship and ship. There was one feature in the paper that had not been mentioned before—viz., that a low freeboard vessel could be driven at the same speed as one that had a high side. The measured mile trial would certainly not bring this feature out. It was hastily inferred that because the "Admiral" class buried themselves forward, this was a detriment, but is must be known that their safety was not endangered thereby. That they could fight their guns in a head sea was important to know. Some doubt was expressed here, as information had reached the speaker, of a very contrary nature, and that solid bodies of water had swept the low deck forward, even entering the barbette. Mr. White explained that in this instance the ship was unfinished and had no guns in place. Sir E. J. Reed understood that certain reports of naval officers on these vessels had been kept back from Parliament on account of the actual behaviour of these vessels. He was in favour of these autumn manœuvres. In his time no money could be obtained for experiments whatever. He congratulated the Admiralty on their change of policy in this respect, and for permitting the subject to be brought up for discussion in public.

Admiral Morant confirmed Mr. White's views as to the "Admiral" class of ships. During the manœuvres he was living on board the "Anson." In a gale of wind on the north coast of Scotland, while going at 9 knots against the sea, and with hatches battened down, there was no time at which the guns could not have been fought. As to habitability, improved ventilation had removed a stuffiness existing in the after parts. A leakage that existed in the fore parts had since been remedied. Artificial ventilation was wanted in the stokeholds, but not forced draught. An instance was quoted where two hours' use of this system in a ship had necessitated the fires being drawn. He would not close his stokeholds for fear of disabling his ship at a critical moment.

Admiral Sir J. Willes considered the manœuvres reflected great credit on the Service generally, the temporary crews being quite new to their work. He thought that what was wanted was a steady gun platform, otherwise the ships would be rendered partly useless for their work, even though they possessed a high speed. Officers would also be chary of going into action with forced draught, owing to the risks involved.

Captain Long mentioned the exigencies of a naval service, and the impossibility of having a big ship everywhere. A high freeboard implied a bad target, and high speed produced large waves. It was desirable therefore to have as low a freeboard as possible. The question was then asked if the forward bulkhead on these vessels could not be constructed to meet the sea better. In common with other naval officers, a verdict was recorded in favour of high speed and against forced draught. While saying this it was argued that some mechanical means must be used for increasing the draught, but this was not to be on the usual plan.

Admiral Sir Vesey Hamilton followed in much the same vein, and commended the Admiralty for returning in some measure to old usages in sending our constructors to sea. It was only by studying the performances of ships at sea that improvements in design could be arrived at, practice, he said, being the highest kind of science after all.

Mr. Baden Powell spoke of the steering question in some of the large ships. He referred to one ship, the "Ajax," which it was not safe to approach within a half-mile, and of the straight keels of the "Admiral" class, an adverse opinion was expressed as to their answering their helms well. There was also a doubt in his mind if a good draught could be had were the funnel shot away altogether.

At this point the discussion left somewhat the purely naval channel, and turned rather into an engineering one. Mr. Fothergill is known to have a special knowledge of forced draught. His experience was that the application of the system was generally at fault. A ½in. draught was no more than what a common chimney gave. It was when we came to 2in. in a closed stokehold, that harm was done by opening the fire doors, and by the rush of cold air on to the tube plates. Why not close the ash-pits instead of boxing in the holds? He had steamers working on this system running to India with ¾in. and ⅞in. pressure for thirty days continuously. He had no trouble in any way, and burnt 40lb. per square foot of grate in an exceptional case. For economical reasons, the actual figure was somewhat lower.

Mr. McFarlane Gray here mentioned the possibility of misunderstanding arising in the matter of these draughts. Instead of a ½in. forced draught being the same as that generated in an ordinary funnel it generally meant ½in. in excess of that due to the atmosphere. The funnel itself would give a ½in., therefore a ½in. draught really signified a total of 1in. As regards forced draught, what was wanted was some means of making fireclay stick to the tube plates and so protect them.

Mr. Sennett said he was associated with Mr. White in the design of the ships alluded to in the paper. Some misconception occurred with reference to the term forced draught. Mechanical draught would be better. In the old days if a funnel were shot away it would be a serious matter. Now the fans would be brought into use, and no difficulty arose. If any trouble had been found it was not due to the system itself, but rather to the excessive use of it by some captains. It must be remembered that forced draught did away with ventilators, and that vessels like the "City of New York" (Holt's line) and those sailing from Holyhead all worked successfully with closed stokeholds. The novelty was in making all the air brought in by the fans go through the fires.

Mr. Durston, the Engineer-in-Chief of the Navy, said that at full power they adopted 1in. air pressure, and were now at the Admiralty making experiments as to the use of fireclay on the tube plates. The authorities were always willing to try any likely system that might be brought to their notice.

Admiral De Horsey hoped the discussion would lead to some practical solution of this forced draught question. Some engineers said the air pressure must be ½in., and others put it down as 2in. If the limit could be fixed, why not fit a valve to blow off like a safety valve does on a boiler? He deprecated the horse-power attributed to a ship being at the forced draught rate if the use of the appliance were prohibited by the Admiralty. He would like to leave out forced draught if he could not, according to the regulations, use it.

Mr. Seaton said he had just come to London behind a locomotive using forced draught. He felt no apprehension. It was no new thing on railways. When the Great Western first adopted it, they had troubles. As the engine stopped and the temperature fell, the tube plates began to leak. All this had been got over, and no doubt the same would be the case when the subject was better understood in marine boilers. We wanted a remedy, and must not condemn the system. The Admiralty would not use North country coal, and they did not design suitable boilers for burning Welsh. The furnaces and combustion chambers were too small, and the grate area too large. The higher the pressure the smaller should be the area of the grate. As to admitting cold air when opening the fire doors, there were mechanical stokers, most certain in their action, which would prevent trouble on this head. As regards screw propellers, those for smooth water were not always suitable when tried on a long voyage in rough weather. He thought the Admiralty used sizes which were not large enough for cruising purposes.

Mr. Martell had doubts, when comparing the scantlings of these ships with merchant ships, if they were equal to the strains required of them. That they held together so well was very creditable to the department responsible for their design, considering the great spacing there was between their frames.

Mr. Archibald Denny said his firm had had experience with forced draught at ½in. to 1in. air pressure for nearly two years. The boilers were in a perfect state still. At the trial a pressure of 6in. even was reached, and no troubles arose.

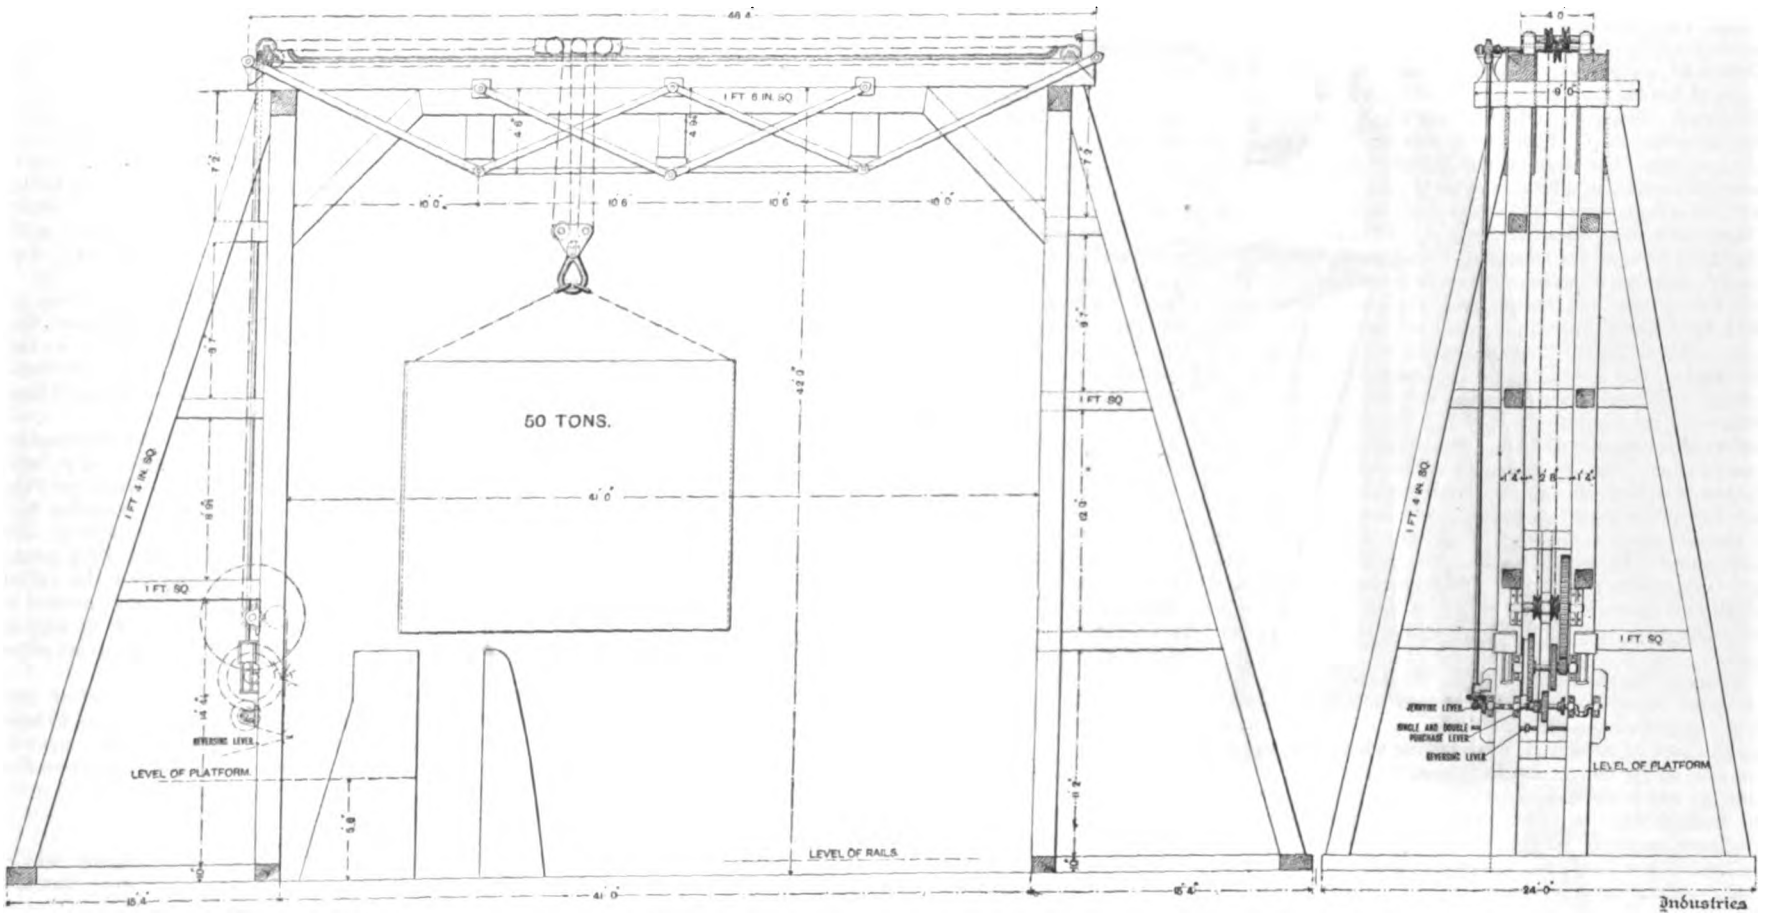
Mr. Yarrow mentioned the using of fireclay some years ago on the tube plates. The difficulty was to get it to expand and contract with the metal. On this account the use of it did not meet with success. As to the 9in. air pressure that had been mentioned, Mr. Yarrow had used 8in. and not been troubled with leakage in any way. This was on a boiler of 1,800 h.p. in use in the Navy. All that was required was a good design of boiler for the work. No special device was necessary.

Mr. White, in his reply, referred to strictures that had been made on the "Rattlesnake," and the so-called strengthenings that had been built in the vessel, due, as it was said, to faulty design originally. To show the error that had been made, Mr. White mentioned the cost of the strengthening of the bulkhead, which was in the wake of the engines, at between £100 and £200. The vessel of the "Sharpshooter" class did on trial vibrate considerably, it was admitted, but on inquiring into the cause it was found that certain pillars had not been embodied in the vessel such as the design indicated. For one-third the midship part of the ship she was without any vertical support. This was stated to be the result of the complexity of the system under which work is carried out under Government. As to the vibration in the "Barham," the answer was found in the fact that this vessel had never yet had her engines turned, but probably the critic was referring to one ship of this class only, it being the practice of the Admiralty to refer to ships of a class without always particularising their names. As to the scantlings of men-of-war, it was rightly contended that no comparison could be made with merchant ships. In the former case you have to support weights, in the latter to carry them in holds, the difference being great subdivision of strengthenings on the one hand to none at all on the other. Clearly, therefore, the scantlings in a warship may be lighter than in that of the unsupported box-form carrier of cargo. Mr. White spoke next of the large guns being used at sea on a low freeboard vessel, and the effect of hydraulic machinery for pointing these massive pieces of ordnance on the object at all variations of the helm and movement of the vessel. The guns of the "Trafalgar" had been fired only 3ft. 9in. above the deck, and no mishap had resulted, as some critics foretold. The steadiness of the platform in the latest ships had been remarkable, for though a totally different distribution of weights had come about under new conditions Mr. White declared himself able to cope with ships of a past era in this respect, notably the "Hercules" and "Sultan." The size of the cruisers has increased as extra speed was desired, till now we find the "Blake" to be of 9,000 tons displacement. If a speed was required equal to the "Teutonic," which is 15,000 tons displacement, the only question was said to be the bill to be paid for this size of vessel. On the forced draught question Mr. White expressed himself as, speaking from a naval officer's point of view, in favour of forced draught, but as wishing to use it only in case of emergency. Here he felt he was undoubtedly on sure ground, for every particle of power that can be got out of the engines would be wanted in an action, and it was only then that a commander of a man-of-war ought to use the auxiliary that was placed in his hands. As to sending naval constructors to sea, this in future would be the rule. The work of the Department was, however, stated to be so great that it is unlikely that many officers in responsible positions would be permitted to see what fleet manœuvring means.

The first paper read on Thursday, the 27th ult., was by Rear-Admiral Colomb, on "The Washington Maritime Conference."

The invitations to attend the Conference were widely spread, and twenty-eight Powers sent one or more delegates. Most of the great Powers sent several delegates, and Great Britain was represented by Mr. C. Hall, Q.C., Rear-Admirals Sir George Nares, K.C.B., F.R.S., Sir Robert Molyneux, K.C.B., and N. Bowden-Smith, Mr. Thomas Gray, C.B., Captain Wyatt, of the P. & O. Service, and Captain Kendall, of the City of Dublin Mail Service.

The programme proposed for consideration stood thus: I.—Marine signals or other means of plainly indicating the direction in which vessels are moving in fog, mist, falling snow, and thick weather, and at night. Rules for the prevention of collision, and rules of the road. II.—Regulations to determine the seaworthiness of vessels. III.—Draught to which vessels should be restricted when loaded. IV.—Uniform regulations regarding the designating and marking of vessels. V.—Saving life and property from shipwreck. VI.—Necessary qualifications for officers and seamen, including tests for sight and colour-blindness. VII.—Lanes for steamers on frequented routes. VIII.—Night signals for communicating information at sea. IX.—Warnings of approaching storms. X.—Reporting, marking, and removing dangerous wrecks or obstructions to navigation. XI.—Notice of changes in lights, buoys, and other day and night marks. XII.—A uniform system of buoys and beacons. XIII.—The establishment of a permanent International Maritime Commission.



There is evidently a double character discernible in the matters proposed for discussion in this programme. There are some divisions which can only be treated internationally as often concerning the ships of different nations equally at the same time. There are others which may be offered for international discussion, with a view to improvement of system, but which are not directly of international importance. Such are: II., Determining the seaworthiness of vessels: III., Draught to which vessels should be loaded: V., Saving life and property from shipwreck; VI., Qualifications for officers and seamen. Of these four subjects it may be said that uniformity of system amongst the nations is not so important as a good system; and that nothing would be gained by calling on a minority of Powers to give up better systems and take to worse because the majority had agreed to do it. But of most of the other subjects it may be said that uniformity is the essence of any system adopted, and that even some sacrifices in efficiency

FIGS. 2 AND 3.—SIDE AND END VIEWS OF TRAVELLING CRANE FOR CARRYING WORK TO BE RIVETED.

might be made, if in no other way could uniformity be secured.

Discussions on the rule of the road at sea, and on the prevention of collisions at sea generally, are so familiar, and differences of opinion are so frankly expressed as between seamen and landsmen, and as amongst seamen themselves, that there is a general impression existing that the whole thing is very abstruse, and terribly complicated. It certainly does contain matter for close and clear thinking, and for highly technical and carefully chosen language. It is a subject, however, not complex in itself, and resting on very clear and determinate principles.

All that was authoritatively laid down on the subject of preventing collisions came before the "Conference on the International Regulations for Preventing Collisions at Sea," extended over twenty-six articles, eleven of them being actual "Rules of the Road," three being of a special and exempting character, and the remainder dealing with signals necessary for carrying out the rules, many of which embraced several sub-sections, and which contained a great many fundamental and highly technical terms, the meaning of which all the Admiralty lawyers on the Conference knew had never been, and perhaps never could be, defined. That such terms should have crept in as the basis of an international law of the highest importance to life and property is, perhaps, not less strange than that they should never have appeared officially until 1863. But the fact that the terms were in the law, and were made the basis of the law when it was first formulated internationally, was a fact which the Conference could not get over.

It was stated that the Conference found the rules hinging on a series of indefinable terms. These terms have all made their appearance since 1856, and were unknown to the rules for preventing collisions before that date. They are as follow:—

1. "Risk of collision." "It was utterly impossible for the Legislature to have determined or described what should constitute risk of a collision," said the Judge of the Admiralty Court in the case of the "Mangerton."*

2. "Keep out of the way of." This phrase has no meaning, except the general one, "not to get into collision with," as it specifies no particular act. If no collision follows the act it is right whatever it is; if collision follows, it is *primâ facie* wrong, whatever it is.*

3. "Wind aft." "A further question arises," says Marsden,† the great authority on the law, "as to how the dividing line between 'running free' and having 'the wind aft' is to be drawn. These difficulties will be found discussed at length in the 'Privateer,' a recent Irish case. In that case the Court appears to have been of opinion that a ship may at the same time be 'running free' and have 'the wind aft.'"

4. "Meeting nearly end-on." "The meaning of 'nearly end on'" says Marsden,‡ "has not been exactly defined. Vessels upon parallel courses, each with the other nearly right ahead, and vessels upon courses making with each other an angle of two, or even three, points have been held to be meeting 'nearly end-on.' But in a case where the courses of the two ships were within a point of being directly opposite, the Privy Council decided that the ships were 'crossing,' and not meeting ('nearly end-on')."

5. "Crossing." This is the converse of "nearly end-on," and the indefinable point, as above, is where "nearly end-on" ends and "crossing" begins.

6. "Overtaking." Marsden says: "There is nothing in the regulations to indicate how one ship must bear from another in order to be an 'overtaking' ship. . . . . Under the regulations of 1863 a rule was suggested by Brett, L.J., in the 'Franconia.' . . . . In a subsequent case, however, doubts were expressed in the Court of Appeal as to the correctness of the rule suggested by Brett, L.J."

Now, the whole law is in motion or not in motion, according to whether there is or is not a something called "risk of collision," and yet no one can decide what that something is. The separate action of each ship, and therefore their presumed mutual action, depends upon whether or no the wind is "aft," whether or no the ships are "nearly end-on," whether or no they are "crossing," or whether or no one ship is "overtaking" the other. And yet, as may be seen, the "whether or no" must be in each case entirely a matter of guesswork at the moment. There are only three definite actions prescribed in the ten "steering and sailing rules": (1) To "alter course to starboard"; (2) to "keep the course"; (3) in narrow channels, to "keep to that side of the fairway or mid-channel which lies on the starboard side of such ship."

So much, he said, for the matter of the law as coming before the Conference for revision. He then dealt with its manner, and it is obvious that any regulations for preventing collisions must consist of two parts: (1) Rules which deal with the motions prescribed to ships on approaching each other; and (2) signals to enable ships to ascertain the situation and make the proper movements. In the existing regulations the cart is before the horse. The signals are put in the primary, and the rules which either dictate, or ought to dictate, the signals, come in the secondary place.

Now as regards the facts on which the law is, or ought to be, founded, and which should be in full view of anybody undertaking its revision: What, he asked, is the law wanted for? when is it required for the mutual safety of two ships? and when are any two ships safe without it? The answer is that in the open sea, or in any space of water where ships are presumably free to act under a law relating to the two ships only, the law is never required unless the two ships are steering for the same point. If they are not steering for the same point law is not required, because both ships are already in perfect safety. If this is so, then what sort of a law is required? The appeal here is to history, and until 1840 history had but one answer. The law provided that one of the two ships, designated by facts which were known to, or presumably known to, both, should be given the right to go on steering for the point, and that the other ship was forbidden, absolutely, to steer for that point, or for any other point in the path which the first ship was pursuing. Of course there were limitations. Although the ships were steering for the same point, one might be so near it, and the other so far from it, that it would be impossible for both to arrive at it at nearly the same time. In such a case no law was required, and no movements were necessary. But by the law, in all cases where each ship was steering for the same point, and where there was the least doubt about the times of arriving there, the ship which had not the right to go on, was bound to steer so as not to pass in front of the other ship. This was the answer which the history of maritime law had given to the question up to 1840. There was then an innovation made with regard

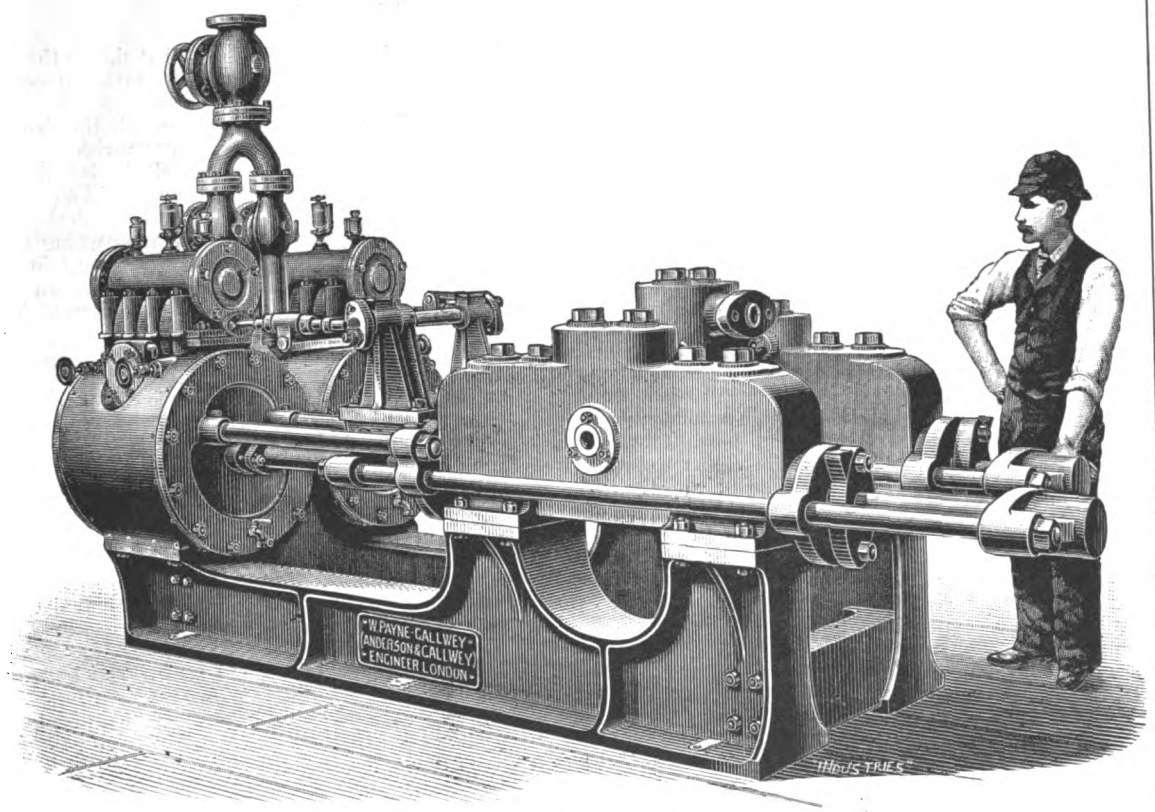

FIG. 5.—DUPLEX PUMP USED FOR CHARGING HYDRAULIC ACCUMULATOR.

to steamers, and a new law appeared which conflicted with the old one in principle, but had the excuse that possibly no way had then been thought of of making the condition of each ship known to the other at night; and also that provision for an exceptional case was mistaken as provision for the general case. This innovation and breach of principle proceeded to swallow up, after the manner of such things, the whole of the old principles, so that by new British laws promulgated in 1854 the old principle absolutely disappeared until 1863. In 1863 there was only the shadow of it left, and the best work of the Conference has been to give substance to the shadow, and to bring us nearer to where we were in 1839.

So much, he said, for the principles of law as applied generally. A question properly before the Conference was, or might have been, whether the simple and general rules of the old law were sufficient for modern times.

To answer this question, the author directed attention to diagrams representing the conditions of approach in ships before they came into collision. It may be said broadly that the danger of collision chiefly arose when ships' courses crossed at a small angle. It seems, then, that if the general principle of law mentioned is suitable for all such cases, but that provision for other cases confuse it, there may be a question whether the other cases had not better be left alone as exceptional. It becomes evident that the mean conditions under which collisions now occur, and against which the law ought to provide, are a crossing angle of about three points of the compass. Make the angle a little larger, say about four points, and we have the crossing angle for ships close-hauled on opposite tacks. It was convenient to take this common case, because it is just the same case now as it was 200 years ago, and the only thing that differs is the law for preventing the ships from coming into collision. This law, when it disappeared from the Royal Naval Signal Books as late as 1868, was thus:—

"When any ships under sail on different tacks, by continuing their course must pass near each other, the ship on the starboard tack is invariably to keep to the wind, and the ship upon the port tack is upon all occasions to give way and pass to leeward, taking care to bear up in sufficient time for that purpose."

As to the qualifications for officers and seamen, the Conference dealt wholly with the question of colour-blindness, on account of its danger with reference to the red and green side lights. He never knew himself a case of collision where colour-blindness was in question. The statements were generally perfectly clear that wrong helm was given deliberately in the face of the colour seen; and as no authoritative teaching had existed to show that it mattered what colour was seen as long as danger was denoted, he had never been able to lay stress on the colour-blind question.

The opinion of the Conference seemed to have been against any decided line being taken with regard to lanes of route for the avoidance of collision. Here again he had never been strong, as he had observed before that collisions did not occur often on any waters which would be included in the lanes proposed. As to the general question of signalling, the Conference agreed that the "system of long and short flashes from a white light"—that was, the existing flashing system—"was better than any employment of coloured lights," and they proposed one or two official signals on that system. They also proposed to insert in the International Signal Book what they called the "Morse Code," meaning presumably the common telegraphic alphabet as used with the flashing system. The maritime countries were invited to consider the establishment of a uniform system of storm warnings. A good many resolutions relating to the notice and removal of derelicts and other obstructions to navigation, as well as notices of changes in lights, buoys, &c., were submitted to the Powers; but, so far as he knew, our own Hydrographical Office already acted in the way proposed A uniform system of buoys and beacons was roughly specified and proposed for adoption. Unquestionably a uniform system was of international importance. The establishment of a permanent international maritime commission was, however, considered "not expedient" for the present. In conclusion, he thought the Conference had done as much as could have been hoped for at its hands. Should such a Conference ever re-assemble, he did not think it should be so numerous. He supposed that some limited number of well-chosen delegates from the four or five Powers most concerned in maritime questions might be found to avoid mistakes as well as the late Conference did, and yet, perhaps, to take still more definite steps in the path of improvement.

(*To be continued.*)

200-TON HYDRAULIC RIVETING PLANT.

THERE is probably no method of working machine tools which is capable of receiving more widespread application than that which embodies in some shape the hydraulic principle. Massive forgings are now operated upon with tools of this character, and, with boiler makers especially, such tools have become not only a useful, but an absolute, necessity in these competitive days. Therefore, to our engineering readers the following description of the largest plant of hydraulic riveting machinery yet erected will be of special interest, and, as an illustration of the growing demands made upon boiler makers to deal with larger and heavier work, it can scarcely fail to indicate the advance of modern engineering.

The plant we illustrate has been designed and erected by Mr. W. Payne-Gallwey, of Messrs. Anderson & Gallwey, of 274–277, Strand, London, for a company of engi-

Digitized by Google

neers and boiler makers in Holland. Some time ago this latter company received an extensive order for some very large marine boilers, and in order that the work should be done as efficiently as possible and also to prepare themselves for similar orders in the future, they determined on having a new hydraulic riveter which should have such a power and size of gap as to be able to deal with the very largest work ever required or likely in the future to be required. The gap of this machine has therefore been made 12ft. deep, and has been given a closing power of 200 tons. It is capable of closing rivets up to 3in. diameter, though most of the work at present will not require rivets of more than 1½in. diameter.

In Fig. 1 (page 313) we show a view of the riveter before it was placed on its foundation, and in Fig. 4 (page 316) a view of the machine when arranged for work; Figs. 2 and 3 (page 315) are side and end views of the travelling crane which is used for bringing the work over the riveter; Figs. 5, 6, 7, 8, 9, 10, and 11 (pages 316, 317, and 320) show various appliances for obtaining the necessary water pressure for the boilers and riveting plant. Figs. 12 and 13 (page 324) give general views of the installation.

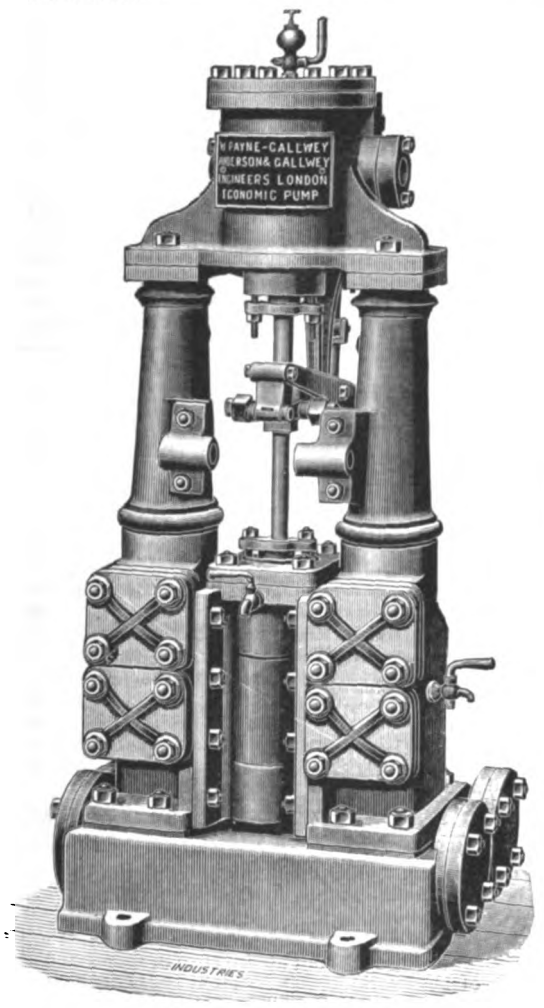

Fig. 6.—Boiler Force Pump.

The nature of the ground upon which the plant is erected was so treacherous, that the customary mode of making the machine framing of a massive casting had to be abandoned, and a new method of designing the main framing had to be arranged.

After much thought had been given to the matter, it was decided to build the frame of steel plates 1½in. thick, and to stiffen them with angles and internal bulkheads. The reduction in weight accomplished by this novel arrangement is very considerable, while the rigidity and stability are very great, as may be judged from Figs. 1 and 4. In the construction of this framing, the rivet holes were drilled in position and the rivets were closed by one of Messrs. Anderson & Gallwey's "Eagle" riveters. The holder up or hob is of solid cast steel, and weighs about 13 tons. It is secured to the frame by two forged steel bolts 8in. diameter, whose threads are swelled up and cut of saw-toothed section, the thrust face of the threads being vertical. Between the hob and main frame there is a distance piece, which is made of plates of box section. The cylinders and rams are all of cast steel. The main or rivet-closing ram is hollow, and within it is the plate-closing ram; by this arrangement a pressure of 100 tons is first brought to bear on the plates to close them; then another 100 tons is put on the rivet; and afterwards the entire pressure of 200 tons is put upon the rivet head and plate.

The steam travelling crane shown in illustrations Figs. 2 and 3 spans the great riveter and the large shop in which it is mounted. It is composed of an oak gantry which has a 41ft. span and is 50ft. high; it is designed to raise and manipulate a complete marine boiler weighing anything up to 50 tons. The power is obtained from two engines, whose cylinders are 8in. diameter by 10in. stroke; double 1in. chains are used, and they work through cast steel pitch wheels. The cross beams are of oak 18in. square, trussed with eye bars.

The hydraulic power is supplied by the duplex horizontal direct-acting pumping engines shown in Fig. 5, page 316. These pumps have two high-pressure steam cylinders, each 22in. diameter by 18in. stroke. The pump ends are 3¼in. diameter, and have double rams connected by side rods. The output is 70 gallons per minute, at a pressure of 1,500lb. per square inch. Two steel locomotive type boilers, shown in Figs. 12 and 13, page 324, supply steam to the pumps and to the crane; each is capable of working the entire plant independently, and can do duty equal to about 130 i.h.p. The exhaust steam is partly used in a feed heater of the horizontal multitubular type, and the rest is discharged up a special upcast pipe, or into the chimney. The accumulator for the riveter is of large proportions, and the tower in which it works and is guided is illustrated in Fig. 7. This tower is a structure composed of 12in. by 6in. rolled joists, stiffened with T braces and angular struts. The whole stands on a base made of 12in. by 6in. joists, which are stiffened at the top and bottom by ½in. plates. Its stability is such as to allow of the canting of the whole, with its loaded counterweight box containing 100 tons, at an angle of 15°, this precaution being taken on account of the treacherous nature of the foundations. Some idea for the necessity of this provision may be gained when it is stated that it has to stand within a few yards from a river bank, and that upwards of eighty 70ft. piles have been driven to obtain a firm base. The accumulator ram is 14in. in diameter, and works in a cast-steel cylinder allowing a 10ft. stroke. The boiler force pump (Fig. 6) is supplied with a lever for hand working in accordance with the requirements of the Dutch law.

The complete plant presents a very massive appearance, and certainly reflects great credit upon the designer. Large as this installation is, Mr. Payne-Gallwey is, we understand, about to eclipse even this his latest effort, and we hope ere long to have the opportunity of describing some other very large machinery on which he is now engaged.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 321.)

PARIS, 1st April, 1890.

IRON.—Though there is an appearance of firmness in the iron markets, in reality the position is less strong than it was at the beginning of last month. Here in Paris not even the appearance is kept up. The merchants are willing to make large concessions to buyers, so that iron may be bought several francs a ton below the official quotations. Prices are maintained in the provincial markets, but the shrinkage of business continues. There is considerable activity in the Haute Marne, where the demand is very brisk for wire and wire-nails. In other districts buyers limit their dealings to the strict necessities of the moment. If the price of coal be reduced—and there are symptoms of a giving way—there will be a drop of several francs a ton for finished iron and steel. The imports of pig iron in the first two months of the current year amounted to 19,485 tons, against 23,066 tons in the corresponding period of 1889. The imports of finished iron and steel were respectively 3,547 tons and 1,132 tons, against 3,707 tons and 1,426 tons last year. The exports were—Pig iron, 39,016 (2,932) tons; finished iron, 14,282 (3,329) tons; and steel, 6,646 (6,123) tons, the figures in parentheses being those for the corresponding period of last year.

STATE OF TRADE.—The Customs returns for the first two months of the year show a steady development of trade. The declared value of the imports in February amounted to 393·4 millions of francs, against 372·1 millions in the same month of last year. Of this increase 20 millions are set down to raw materials. The value of the exports in February of the current year amounted to 277·0 millions against 259·9 millions in the same month of 1889. The increase in manufactured goods is from 246·5 millions to 264·9 millions for the two months. It is worthy of notice that the imports of wool ten years ago were valued at only 30 millions for the first two months of the year, while this year the value is 82 millions. The growing importance of the woollen goods industry is hereby made manifest. A noteworthy feature among the exports is the great increase in the value of articles of women's dress (ready-made), which for the first two months of the current year appears as 8·4 million francs, against 2·5 millions in 1889. The exports of machinery for the same periods show an increase from 5·2 million francs to 7·8 millions.

COLLIERS AND MILITARY SERVICE.—M. de Freycinet has given an assurance that the colliers will not, in case of war, be called on for military service, the supply of coal being regarded as too important a matter to be interrupted in such circumstances. Coal being declared contraband of war, the foreign supply would be wholly cut off.

BERLIN, 31st March, 1890.

IRON.—The number of blast furnaces now in blast in the Upper Silesian district is thirty, the weekly output of which is from 2,700 to 3,000 tons, a quantity insufficient to meet the requirements of consumers. Hence the market is very firm. Makers of finished iron and steel have plenty to do. Fresh orders come in freely. Prices are therefore easily kept up. At the machine works of the Donnersmarckhütte a number of Schmidt's patent tubular boilers are being constructed for export to China, Japan, and Australia. Business in the Berlin market is becoming more active. The tone of affairs generally is strong and hopeful.

THE FRANKFORT EXHIBITION.—The programme of the International Electrical Exhibition, to be held next year at Frankfort on-the-Main, has just been issued. There will be twelve sections, as follow:—(1) Motors for electrical purposes (steam, water, air, and gas); (2) generation of electricity; (3) conduction of electricity—all means of conducting and auxiliary apparatus; (4) electrical accumulators and transferring apparatus; (5) electrical power transmission in its application to industrial purposes of all kinds; (6) electrical lighting, with special division for installations of all sorts; (7) telegraphy and telephony; (8) electric signalling; (9) electro-metallurgy and electrolysis; (10) surveying instruments, apparatus, acoustical and optical instruments relating to electro-technics, and means of instruction; (11) application of electricity in medicine and surgery; (12) electro-technical literature.

GERMANY'S FLOATING EXHIBITION.—The success of this undertaking is now fully assured. So far, 360 large manufacturers have taken part in it, and the support of many others is in prospect. The plans of this exhibition steamer have been finished, and tenders have been invited from three first-class German shipbuilders for its construction, which is to take about a year. The dimensions are to be—length, 570ft.; breadth, 70ft.; and depth, 45ft. The largest ship at present afloat, the "City of New York," is 560ft. long, by 63ft. wide, and 44ft. deep. Hamburg was at first intended as the starting-point of the Floating Exhibition, but Bremerhafen has now been chosen.

THE WATER POWER OF THE RHINE.—Several manufacturers of Winterthur are now engaged in a scheme for tapping the energy of the Rhine at the Schaffhausen waterfall. Water to supply 1,500 h.p. is to be withdrawn from the river, and its energy will be transmitted as a current of electricity to the factories at Winterthur. At present the scheme is somewhat limited, but no doubt in case of its success an extension will be thought advisable. The manufacturers for whom the work has been carried out congratulate themselves on their independence of coal strikes.

GAS ENGINES.—As an indication of the profitable nature of the gas engine business, it is interesting to note that the Gas Motoren Fabrik Deutz, the holders of the "Otto" patent for Germany, have made a profit last year of 1¼ million marks. They will pay a dividend of 36 per cent. as compared with 31 per cent. for the previous year.

LABOUR.—Labour complications continue to disturb all the great industries of the country, and to give rise to much anxiety. From all parts we hear of fresh strikes. A large number of the textile hands in the Chemnitz district are idle. Some serious strikes have occurred among the coal miners of Westphalia, which are likely to develop into another grave conflict between the colliery owners and their men in that locality. Everywhere there is manifested a feeling of discontent and a determination to advance further the rate of wages.

PRICES OF LOCOMOTIVES.—The following are the tenders for the locomotives received here on the 17th inst. For 35 express engines with tenders:—The Hannoverische Maschinenbau-Actiengesellschaft tendered for 10, at 50,900 marks; Henschel, of Cassel, for 13, at 50,900 marks; and A. Borsig, of Berlin, for 12, at 51,000 marks. For 45 ordinary passenger engines with tenders:—Henschel tendered for 13, at 48,850 marks; the Elsässiche Machinenfabrik, at Gravenstaden, for 17, at 48,900 marks; the Berlin Maschinenbau-Actiengesellschaft, 15, at 48,950 marks. For 140 ordinary goods engines with tenders: Schichau, of Elbing, tendered for 20, at 43,500 marks; Henschel, for 39, at 45,350 marks; the Hannover Maschinenfabrik, for 25, at 45,390 marks; the Stettin Vulcan Works, for 25, at 45,400 marks; the Berlin Maschinenbau-Actiengesellschaft for 40, at 45,420 marks; and the Maschinenfabrik Hohenzollern, of Düsseldorf, for five, at 45,450 marks each.

THE ZINC-WHITE INDUSTRY.—The high prices of zinc have seriously restricted the trade in zinc-white. The total production of the Silesian district last year amounted to only 715 tons, against 2,369 tons in 1888. Among the substitutes for zinc-white, zinc dust, which is sold at three-fourths the price of the metal, is being more and more largely used. Another substitute, soap-stone, used from time immemorial in China and Japan for painting metal-work, is also growing in favour here.

VIENNA, 31st March 1890.

THE IRON MARKET.—There is no change to be noted in the iron market, and the improving situation which began last year is continued. Last year's returns show that the production of pig iron was far behind the demand, and that the import of pig has increased in comparison with the previous years. However, most of the finished iron has still to be imported. The following is a table of the imports of the last two years:—

	Tons. 1888.	Tons. 1889.
Pig iron	62,820	81,134
Crude iron	4,180	12,008
Ingots	1,412	1,961
Rails	500	1,376
Wires	993	1,342
Foundry iron	1,919	2,169
Wrought-iron tubes	1,502	2,067
Railway wheels	383	678
Wire ropes	127	230
Bar iron	8,500	4,300
Sheets and plates	202	106
The exports were as follow:—		
Pig iron	6,336	7,519
Crude iron	2,833	978
Foundry wares	2,153	2,389
Ordinary iron and steel ware.	5,863	7,048
Wrought-iron tubes	237	559
Nails	543	1,047
Boilers	113	340
Wire	716	885
Rails	724	939
Sheets and plates	2,034	1,853
Screws	115	85

THE COAL MARKET.—The situation of the coal market continues firm, and prices are still increasing. The export steadily advances. The export coal traffic has reached such a height that the Bohemian Members of Parliament are bringing in a Bill for its regulation, in order to protect home industries from the scarcity of fuel. Another sign of the situation of the market is the fact that the Bustehrad Railway, which is principally occupied with coal traffic, is doubling the tracks of some of its lines.

ELECTRICAL ENGINEERING.—At the Jubilee Exhibition, to be held at Prague, there will be engines of 1,000 h.p. for supplying the electric current. It is intended to use 350 arc lamps and 650 glow lamps, and the remainder of the current will be employed for driving certain machines.—On the Budapest electric tramway the electric light is being used; the current for supplying the lamps is obtained from the accumulators on the cars.—Two large central electric lighting stations are about to be erected, one at Fiume and the other at Linz.—It is proposed to connect the towns of Fiume and Abazzia by means of an electric tramway.

PAPER.—The paper trade has been excellent all through the empire during the past year. The home demand has been good, but the export to eastern countries has been better. The Leykam Josephsthal Company is paying a dividend of 7 per cent. on last year's trade.

BRUSSELS, 1st April, 1890.

THE IRON MARKET.—The position of the iron market has slightly improved. Several new orders for exportation have come to hand, and have filled up the gap which was beginning to make itself apparent. In merchant bars some business has passed at 11·5fr. In sheets the trade continues fairly good, and buyers do not make any difficulty about a price of 22fr. It is proposed to put into blast some more blast furnaces in the Charleroi district, a step which will be welcomed by collieries and rolling mills. The Société des Forges have finished the construction of the two-storey iron house for the Congo. The building will be erected at Oiseau before it is sent to its destination, and it is expected to be ready by the 10th inst. La Société des Conduits d'Eau of Liége have just sent off 500 tons of steel water mains to Denmark. To-morrow the tenders will be opened for the supply of 2,600 tons of steel rails of the Vignoles type, 52 kilogs. per metre, for the State railways.

THE COAL MARKET.—The coal market continues to be very animated. Concessions, however, are more easily gained from the sellers in the renewal of orders; in fact, one might safely count on the new prices being a shade lower than the former ones. Some impatience is manifested as to the result of the adjudication of the State Railways on the tenders for the 75 lots of 2,000 tons each of locomotive coal; and it is probable that business will be retarded in order that the state of the market shall be fully ascertained before any further contracts are entered into. It was decided a short time ago that the railways should have sufficient fuel in stock to last for 75 days; now, however, the Administration has thought proper to reduce this to 30 days. Close burning coal is quoted at 15fr., and *fines demi-grasses* at 16fr.; coke is still at 35fr.

THE GLASS TRADE.—The state of the glass market does not improve; prices lack firmness, and further concessions are being granted. The scheme for the regulation of the trade in glass with the United States has unexpectedly collapsed on account of unforeseen opposition, and the consideration of the project stands adjourned for the present.

DÜSSELDORF, 1st April, 1890.

IRON.—The uncertainty of the situation arising out of political changes and recent developments of the labour question has caused a serious shrinkage of business in the iron markets. There is hardly anything doing in pig iron. The absence of buyers has not yet led to weakness in manufacturers' prices, because the blast-furnace owners are sold far forward, many of them to the end of the year; but the merchants are giving way. Forge and foundry pig may now be bought from second hands several shillings a ton below manufacturers' prices. The market for finished iron and steel continues active, but the volume of business transacted is considerably less than it was a month ago.

COLLIERS' WAGES.—Troubles are again breaking out in the coal mining industry. Partial strikes have occurred in several places, and these interruptions of the work of production tend to become more numerous and more serious. The latest of these disturbances reported from the mining district is a strike at the "Consolidation Colliery" at Schalke, one of the largest and best managed mines in the country. The men demand an advance in wages and a reduction of the working day to eight hours, including the time occupied in winding. The published accounts of the company show that the average wages of all underground hands, after the cost of blasting powder, timber, and oil had been deducted, were in the first quarter of 1889, 3·08 marks, in the second quarter 3·32 marks, in the third quarter 3·49 marks, and in the fourth quarter 3·58 marks per shift, an increase of about 16¼ per cent. in the year. A further increase has taken place since the beginning of the current year, making the rise in a little over twelvemonths upwards of 20 per cent. This is an average for all hands, be it observed. The advance in heavers and putters' wages in the same time is but little short of 40 per cent. The men now demand a further rise of no less than 50 per cent.

COMPETITION IN THE IRON TRADE.—The relative state of the iron trade in Germany, Belgium, and France, as manifested in the ability of manufacturers to compete one with another in foreign markets, is significantly shown by the recent tendering for 150 Martin steel tyres of 866mm. and 140 of 900mm. diameter for the Roumanian State railways. The prices are f.o.b. Galatz, except in the case of Dietrich & Co., of Niederbronn, whose price is free on trucks at the frontier railway station of Verciorova. German firms: Reinische Stahlwerke, at Ruhrort, 17,085fr.; Phœnix Actiengesellschaft, at Laar, near Ruhrort, 18,760fr.; Bergwerks and Hütten-Verein, at Hörde, 20,415fr.; Oberbilker Stahlwerk, at Oberbilk and Düsseldorf, 21,574fr.; Union Actiengesellschaft, at Dortmund, 22,110fr.; Fried. Krupp, of Essen, 25,579fr.; Georgs-Marien Bergwerks & Hütten-Verein, at Osnabrück, 23,852fr. Belgian firms: Société John Cockerill, at Seraing, 18,961fr.; Société des Aciéries d'Angleur, at Renory, 20,100fr. French firms: Société des Aciéries et Forges, at Firminy, 19,095fr.; Schneider & Co., of Creusot, 19,430fr.; Compagnies des Hauts-Fourneaux, &c., at St. Chamond, 20,100fr. Dietrich & Co., of Niederbronn, in Alsatia, tendered 20,740fr.

HIGHER PRICES FOR PAPER.—At a meeting of paper-makers held here a few days ago, at which nineteen firms were represented, it was resolved unanimously to advance the prices of packing paper forthwith to cover the additional cost of the raw materials of manufacture, which have increased fully 15 per cent. in price within the last six months. The rates for paper are to be advanced in a like proportion. The trade in packing paper with England is large and constantly growing.

LILLE, 1st April, 1890.

IRON.—The iron market continues quiet and the prospect discouraging. The fresh orders coming to hand are not sufficient to keep the works going. It is hoped that the early spring which we are now enjoying will stimulate the business in building iron. Prices are as follow:—For bars and joists, 156s. to 160s.; common plates, 196s.; steel plates, 216s. a ton Manufacturers maintain these rates firmly, but merchants are ready to make some concession to tempt buyers. Founders are well provided with work. On the whole, the tone of the market is weaker than it was a fortnight ago.

TEXTILE MANUFACTURES.—The situation of the linen goods trade continues satisfactory. The demand is brisker than usual at this time of the year, and there are indications of greater activity as the spring advances—greater, that is, than the average of past years, for some falling off in the demand may now be expected. In the ordinary course of things the busy season comes to an end with the month of March. From Roubaix we learn that business in woollen goods is very slack. Of fresh orders to close the season there are practically none. The prospects for next winter's trade are said to be very good.

FLAX AND YARNS.—The flax market continues animated for home-grown produce. The demand is brisk, and as there is not a large stock on offer, prices remain firm. The market is quiet for Russian produce, with no alteration in prices. For tows of good quality full prices are easily obtained. Yarns are in brisker demand. Jute yarns are still an active market, at former prices.

AMSTERDAM, 31st March, 1890.

THE AMSTERDAM WATERWORKS.—The Town Council of Amsterdam will be asked to continue the Commission appointed for the supervision of the concession of the Water Works Company.

ELECTRIC LIGHTING AT AMSTERDAM. The well known firm of electricians, Messrs. Siemens & Halske, of Berlin, have withdrawn their tender for the electric lighting of the greater part of the Dutch capital.

NEW AGRICULTURAL COMPANY.—The Official Gazette has published the articles of Association, as approved by the King, of the Netherland South African Agricultural Company, established at Amsterdam, with the object of promoting land cultivation, cattle rearing, and dairying in the South African Republic. The capital is 2,000,000 guilders.

THE PETROLEUM TRADE AT AMSTERDAM.—The "petroleum harbour" at Amsterdam does not seem to have answered the purpose for which it was established at very great expense. At least, the town authorities have laid a proposal before the Town Council to let the whole of the property, if possible, to a syndicate or combination, that will endeavour to establish a petroleum depot and trade there as originally intended.

THE MAILS TO EAST AFRICA.—It was rumoured that Rotterdam had been selected as the Dutch port of call for the steamers in the new subsidised German mail service between Hamburg and East African ports. This rumour has proved premature, the German Government having come as yet to no final decision on the point. The Rhenish provinces and Southern Germany are in favour of Rotterdam, but the Hamburg people seem to prefer Amsterdam

LABOURERS' DWELLINGS IN AMSTERDAM.—The Amsterdam Association of Labourers' Dwellings is enabled to pay for the past year a dividend of 2½ per cent. upon the ordinary shares. At the end of 1889 the society still owed the city of Amsterdam upwards of one million guilders for advances made, upon which it had to pay interest at a rate of nearly 5 per cent. Last year it received 91,000 guilders in rents, and 15,000 guilders was repaid to the city of Amsterdam. This is one of the largest, but not one of the most prosperous, building societies of Holland.

INCOME TAX REJECTED.—The Second Chamber of the States-General has rejected by a very narrow majority the Income Tax Bill, which had been introduced by some private members. They were supported by the Liberal party, but opposed by the Government and its adherents, although the Ministers had to admit that a readjustment of taxation, so as to increase the land tax and to get at the holders of securities to bearer, was urgently required, as urgently as the reorganisation of the communal finances and the lightening of the salt tax. The Government has also a Bill pending imposing customs dues on foreign goods imported *ad valorem*.

THE WATER QUESTION AT AMSTERDAM.—The Hill Water Supply Company, an English company which has contracted to supply the Dutch capital with water collected in the Dunes near Haarlem, has been called upon to remove the defects in the system of distribution and to increase the supply, thereby avoiding the recurrence of the "water famine" of last year. It will be recollected that a special committee reported that the company was evading the stipulations of its charter by using a low pressure in the Dunes, and thereby preventing a "waste" of water, but in reality creating an artificial scarcity caused by a defective system of collecting and intercepting the hill water. It was proposed to increase the pressure, and provide for a better distribution of water from the Dunes to Amsterdam. The Hill Water Supply Company has been "invited" to do both things, and it has signified its willingness to execute the necessary works, which are to be done under the supervision of the town authorities.

COPENHAGEN, 29th March, 1890.

SHIPBUILDING IN NORWAY.—Last year the Norwegians considerably increased their merchant fleet. At the beginning of the present year there were in the course of construction in Norway 36 steamers, with an aggregate tonnage of 15,775 tons, and 33 sailing vessels, with a tonnage of 15,330 tons.

STEAM TRAMWAY IN DENMARK.—The steam tram from Copenhagen along the Sound as far as Klompenborg, about six miles, is not doing well. The receipts for last year amounted to 177,099kr., but as the expenses were 187,474kr., there was a loss on the year of 10,375kr., against 18,722kr. for the previous year and 7,788kr. for 1887. On the other hand the Copenhagen horse tramways are as a rule doing well—some of them very well indeed.

GRAIN ELEVATORS AT ST. PETERSBURG.—On account of the unsatisfactory and antiquated state of the St. Petersburg quays, there has for years been a decided want of despatch in the loading and discharge of vessels. Several attempts have been made to bring about improvements in this respect, among others by an American syndicate, which offered to supply the whole of Russia with grain elevators. The matter was allowed to rest, however, till two Russian gentlemen, last spring, obtained a concession for the erection of elevators at St. Petersburg. They have lost no time in setting about the work, and one elevator building has already been ready for some months. Its capacity is considerable—45,000,000lb. of grain.

SHIPBUILDING AND ENGINEERING.—The Burmeister & Wain Engineering and Shipbuilding Company, Copenhagen, the largest establishment of its kind in Denmark, held its annual meeting on the 15th inst. The business during the past year showed a very considerable advance. New vessels had been built with an aggregate tonnage of 6,643 tons against 2,200 tons for the previous year. The gross profits on the year were 801,000kr., and the net profits amounted to 496,036kr.—The United Steamship Company, of Copenhagen, have issued their report for last year, from which the following particulars will be of interest: The amount of freights during 1889 was 13,923,044kr. The expenses for all the vessels for repair, overhauling, &c., were 799,175kr., and working expenses amounted to 9,650,066kr., making a total of 10,449,241kr. Marine and fire insurance incurred an expenditure of 238,214kr., managing expenses amounted to 259,433kr., and in interest has been paid 318,394kr. The surplus on the year, therefore, amounts to 2,952,044kr., of which 1,129,838kr. is net profit.

MADRID, 31st March, 1890.

RAILWAY CONCESSION.—A concession has been granted to Messrs. Murrieta, of London, to establish a railway to go from some mines in the vicinity of Baracaldo to the River Galindo for shipment of iron ores.

THE VINE DISEASE IN SPAIN.—The increase in the number of vineyards in Spain attacked by phylloxera is shown by the following table:—

Provinces.	Hectares.
Gerona	26,516
Barcelona	2,569
Tarragona	439
Malaga	84,000
Granada	9,429
Leon	8,310
Almeria	3,214
Orense (Galicia)	2,529
Salamanca	326
Total	137,332

The value of the crops lost annually is calculated at about £1,250,000. Much has been done to stop the disease, but nothing successful has been found so far. Lately some new ideas on mineral manures of M. Georges Ville, the well-known French professor, seem to offer more hopes than anything previous as a cure or preservative.

ANTIMONY ORES.—The first lot of antimony ore, of great yield, from the Zalamea de la Serena Mines, in Estremadura, has been despatched from the mines for England. A large sample of this ore, sent to Germany, was analysed, and found to contain 15 grammes of gold per ton. As a rule, all the ores of that place, both antimony and silver lead, have shown more or less gold, but the company do not yet look upon their property as a gold mine.

RAILWAYS IN CUBA.—The largest concession for a system of railways that has ever been made in one lot by the Spanish Government is to be made shortly for a number of lines to be called the "Central Railway of Cuba." The estimates for this line come up to the large sum of £4,950,000. The Government invites tenders, guaranteeing 8 per cent. interest. The conditions are of a rather complicated character, but the belief is that Mr. Ivo Bosch, the Catalonian banker, will tender for the concession. Mr. Bosch took up the Porto Rico railways and the Linares and Almeria line. His plan is supposed to be to issue a great number of debentures in proportion to the cost of the work.

NEW YORK, 22nd March, 1890.

THE COAL MARKET.—The anthracite coal trade is still in a dull and depressed condition, but prices are no weaker than they were last week. The cold weather has caused a good demand on retailers and improved the trade somewhat. The decrease in the output for February is a good feature in the present condition of the trade. The official figures show about 1,800,000 tons, or 200,000 tons less than the allotment. The production of coal since the 1st of January is 400,000 tons below the average consumption for January and February during the past four years. The production for 1890 to date is 600,000 tons less than for the same period in 1889, and the whole of that year was nearly 3,000,000 tons less than 1888. These facts must tell on the trade in time, and the market is sure to take 35,000,000 tons during the current year. The present dull season is likely to continue until July, as stocks are large, but there seems to be no reason why the trade in the latter half of the year should not be active and at good prices.

NEW LINE OF STEAMERS TO JAPAN.—Contracts providing for a monthly line of steamers between Portland, Oregon, and Asiatic ports were executed on the 3rd inst. in San Francisco by the Union Pacific Railway officials and Frank Upton, of Kobe, Japan. The first steamer will arrive in Portland in June with a cargo of new crop tea.

SUBSIDIES RECOMMENDED FOR STEAMERS.—The report of the Pan-American Committee on communications across the Atlantic was presented to the Conference a day or two ago. The committee recommend that aid be given one or more lines of steamers between ports in the United States and those of Brazil, Monte Video, and Buenos Ayres. The conditions imposed are that the companies receiving Government aid shall establish a fast bi-monthly service between the ports named, with steamers having passenger and freight accommodations, and carrying the mails. The speed of steamers is to be at least sixteen knots per hour, and the tonnage not less than 5,000. The committee also recommends an auxiliary line of freight steamers twice a month, having a speed of twelve knots. Brazil and the United States are to pay one-half each of the amount the lines receive. The contracts are to last ten years, and will take into consideration that existing between Brazil and the present line.

TRYING NAVAL GUNS.—A test has been made of the "Vesuvius" gun for throwing cartridges charged with gun-cotton. Several dummy shots were fired, and then one loaded cartridge from each gun, each shot striking over a mile away from the vessel. The cartridges weighed 504½lb. to 510½lb., and carried something over 200lb. of gun-cotton. The first of the cruiser "Baltimore's" 8in. guns has been tested at the naval proving grounds, Annapolis. A charge of 110lb. of American brown powder gave to the projectile of 250lb. weight an initial velocity of 2,130ft. per second, the pressure being only 13 tons per sq. in.

THE IRON AND STEEL TRADE.—There has been no improvement in the outlook for the iron trade during the past week. Consumers are not inclined to take more than is absolutely necessary while the market is in its present unsettled condition, and producers are finding the cost of manufacturing continually increasing. A continuation of the present condition of affairs will send prices below the paying point, while a moderate demand would be very likely to send them up again. But little is doing in pig iron, as neither buyers nor sellers are willing to name figures on good-sized lots or for later delivery that are at all near the market. Several of the heavier consumers will need iron soon, but it is doubtful whether they will take more than sufficient to cover present needs. In manufactured iron matters are in about the same condition. In bar iron a few large orders have made the demand a little heavier, but prices are unchanged. A number of mills are running out their old orders, and are becoming anxious for new business. The demand for plates is fair, but prices are falling off. Makers claim that there is plenty of business for the near future. Steel rails are dull. There is considerable unwillingness to pay the high prices asked for large lots, and buyers continue to make their contracts only for their month's supply. Mills have plenty of other work on hand, and can afford to wait.

PHILADELPHIA, March 21st, 1890.

A LARGE STEEL OUTPUT.—The Scranton Steel Works last week exceeded the record in America in the manufacture of steel ingots by 414 tons with two 6½-ton converters, the total output being 5,456¾ tons against the previous run of the Lackawanna Iron and Coal Company's output of 5,042¾ tons with two 7-ton converters. The company also record the largest turn and day record during the week, the former being 800 tons, and the latter 1,400 tons.

A FAST RUN.—Some days ago the Pennsylvania Railroad Company ran a special train from New York to Washington, a distance of 231 miles, in 4 hours 19 minutes, including stoppages, making the fastest run ever made between the two cities. The time to Philadelphia was 94 minutes, and the distance 90 miles. The occasion was the transportation of a theatrical company playing in New York to take part in a benefit for the Actors' Fund in Washington. The company played in New York again the same evening.

THE EDINBURGH EXHIBITION.

SINCE our last report great progress has been made with this undertaking, and it is confidently expected that it will be quite ready for the opening on the 1st of May. The principal buildings are now completed, with the exception of the internal decorations, and will very shortly be ready for the reception of exhibits. It is perhaps rather soon to express an opinion as to the general appearance of the structure, but it is certainly not very ornate; in fact, the Machinery Hall is severely plain, and, with its long corrugated roof, looks more like an engineer's workshop than anything else. The interior is of a totally different character, and nothing but admiration is expressed, especially for the design of the trussed wood roof. On the whole, perhaps the Executive were right in reducing the cost of the buildings by having as little decoration as possible, and the money saved by this policy will doubtless be spent in a way more appreciated by a Scotchman. The annexes and various auxiliary buildings are also in a forward state, while the grounds and approaches are being rapidly got into order. As we have previously mentioned, a complete covered way, partly in the form of a verandah, extends from the main entrance to the extreme end of the range of buildings, a distance of about half a mile, and will form a delightful promenade when the weather is not favourable for outside amusements. A large staff is at work in connection with the electric light installation, and the boilers have been built in place. Messrs. Brown Brothers, of Edinburgh, are providing one of their combined steam and hydraulic derricks, to lift three tons; it will command the railway siding, and assist in discharging exhibits.

BREAKDOWN OF THE "CITY OF PARIS."

AT the end of last week considerable anxiety was felt about the safety of the Inman liner the "City of Paris," which was several days overdue; and as the weather had not been stormy, it was feared that the machinery had broken down or a collision had taken place. Telegrams from all parts of the world were received making inquiries about the ship, but it was not till Saturday morning that the news was wired from Crookhaven that

Digitized by Google

the "Paris" was in tow and everyone safe on board. The captain's report, handed to the Press by the Inman agent, is as follows:—"On Tuesday, the 25th inst., at 5.30 p.m., when 216 miles east of the Fastnet, the starboard engine broke down from an unknown cause. The cylinders went to pieces, injuring the bulkhead and breaking the injection and water-pipe connection, allowing a considerable quantity of water into both engine-rooms in the adjacent section. No one on board was injured." It was soon evident to all that the accident was serious, and that it might be followed by grave consequences, as the vessel at once began to fill, and it required all the efforts of the crew to keep the water from increasing. For two days after the accident the ship drifted aimlessly about without sighting another vessel, but on Friday morning the White Star "Adriatic," bound from Liverpool to New York, was sighted, and its captain offered to take off her passengers and take them to New York, but this was declined. The "Adriatic" then steamed away, and sent to their assistance the London steamer "Aldersgate," bound from New Orleans laden with cotton. At the same time the chief officer, Mr. Passo, was despatched in the life-boat to Crookhaven, so as to communicate with Liverpool for help. The American liner "Ohio" also bore down upon them, and a considerable number of tugs, and all, with the exception of the "Ohio," accompanied the "City of Paris" to the entrance of Queenstown Harbour. While at Queenstown a thorough examination of the ship was made by divers, by whom it was discovered that there was no hole in the bottom as was expected. From their searches it appeared that the sea had gained admittance to the holds owing to the bursting of the injection pipes which fed the condenser with sea water. These pipes were at once plugged, and the water pumped out of the holds. In a short time the vessel drew her natural draught again, and she was at once propelled to Liverpool by her uninjured port engines. The repairing work will unfortunately be tedious and expensive, and she will hardly be able to resume service this season.

Notices of Meetings.

THIS WEEK.

SHEFFIELD SOCIETY OF ENGINEERS.—Saturday, April 5. Lecture by B. H. Thwaite, C.E., of Liverpool, "On the Development of the Open-Hearth Steel Furnace."

NEXT WEEK.

ROYAL INSTITUTION.—Monday, April 7, at 5 p.m. General Monthly Meeting.

THE INSTITUTION OF CIVIL ENGINEERS. Tuesday, April 8. No Meeting. Friday, April 11, at 7.30 p.m. Paper to be read: "Description of the Roof over the Carlisle Markets," by Mr. F. P. Reynolds. Tuesday, April 15, at 8 p.m. Paper to be read: "The Application of Electricity to Welding, Stamping, and Other Cognate Purposes," by Sir Frederick Bramwell.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, April 10, at 8 p.m. Papers to be read: "On Signalling Across Rivers in India," by Mr. W. T. Melhuish; "The Diathermancy of Air in Relation to the Efficiency of Incandescent Lamps," by Mr. Frederick Higgins.

PRICES CURRENT, 2ND APRIL, 1890.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brocklebank, Manchester, report as follows:—

COPPER during the past week showed a decidedly stronger tone, which was attributed to the scarcity of cash warrants offering, together with an improved demand. The highest point was reached on the 27th ult, when quotations were £48 15s. to £49 cash, but the improvement was not maintained, and values have since receded, to-day's prices being £47 12s. 6d. to £48, with a steady trade reported. Manufactured still £61 sheets and £64 bottoms, with small business doing.

TIN continues without animation, business done being unimportant. Quotations for foreign are about 5s. easier. To-day's prices, £90 2s 6d. to £90 10s. cash.

LEAD continues quiet, with no practicable change in prices.

SPELTER: Small business doing and prices unchanged.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Prices of caustic soda, soda ash, and soda crystals remain unchanged, demand being very strong and supplies limited. Bleaching powder is quiet. Rather more business is doing in acetates of lime at lower prices. Acetate of soda is more inquired for, and high figures are asked. Acetates of lead dull. Benzoles are again easier. Only a moderate business is being done in sulphate of ammonia, and prices are barely steady.

SHIPBUILDING NOTES.

ON the 21st ult. Messrs. John Blumer & Co., North Dock, Sunderland, launched the steel screw steamer "Trinidad," built to the order of the Trinidad Steamship Company, Limited, London. The vessel has been specially designed for the iron ore trade. Water ballast tanks on the Macintyre principle are fitted to each hold. The principal dimensions are:—Length, 240ft.; breadth, moulded, 34ft.; depth, moulded, 18ft. 1in. The deck erections consist of long raised quarter-deck, short bridge-house, and top-gallant forecastle. The engines and boilers have been constructed by Messrs. Alley & Maclellan, Glasgow.

ON the 22nd ult. Messrs. John Priestman & Co., Southwick, Sunderland, launched the screw steamer "Siam," built to the order of Messrs. Russel & Spence, Glasgow, for Jan Kinching, Siamese Consul-General, Singapore. The vessel is of the awning-deck type, and of the following dimensions: Length, 258ft.; breadth, extreme, 36ft.; depth, moulded, 22ft. 10in. The main deck is of iron sheathed with wood, and the upper deck and houses of teak. The engines and boilers have been constructed by Messrs. Hutson, Corbett, & Co., Glasgow.

ON the 22nd ult. Messrs. Ropner & Son launched from their North Shore Shipyard at Stockton a steel screw steamer, built to the order of Messrs. R. Ropner & Co., of West Hartlepool. Her dimensions are as follow:—Length over all, 282ft. 6in.; breadth, 38in. 10in.; depth, moulded, 21ft. 11in.; and deadweight capacity, 3,300 tons. She has a short poop, raised quarter-deck, long bridge extending to foremast, short well, topgallant forecastle, cellular bottom for water ballast, four steam winches, multitubular donkey boiler, and steam steering gear. She is built on the web-frame principle, and her holds will give large stowage for cargo. She will be fitted with triple expansion engines by Messrs. Blair & Co., Limited. As she left the ways she was christened "Newby."

ON the 24th ult. the Blyth Shipbuilding Company, Ld., launched from their building yard at Blyth a steel cargo steamer. This vessel is 228ft. long, 32ft. broad, and 16ft. 4in. deep, and has been constructed on the cellular bottom principle for water ballast. There are powerful steam winches to each cargo hold for the rapid loading and discharging of cargo, and a patent windlass on forecastle deck for working the anchors. The steering arrangements consists of a compact hand and steam steering gear fitted up in wheelhouse on the bridge. The engines are of the triple-expansion type, with cylinders 16½in., 26½in., and 43½in. in diameter by 33in. stroke, and they will be made by the North Eastern Engineering Company, Ld., of Wallsend. As the vessel left the ways she was named the "Matteo Premuda."

ON the 20th ult. Messrs. Robert Thompson & Sons, Southwick, Sunderland, launched the steel screw steamer "Ona," built to the order of Messrs. Bailey & Leatham, Hull. The vessel has a straight stem, elliptical stern, short full poop, raised quarter-deck from poop to after end of engine-room, and partial awning deck to stern. The principal dimensions are:—Length, 280ft.; breadth, moulded, 38ft. 10in.; depth of hold, 19ft. 6in. The four large cargo hatchways are provided with steam winches, and the deck machinery also comprises steam steering gear and a direct steam windlass. The engines are of the triple expansion type, the cylinders being 21in., 35in. and 57½in. in diameter and 39in. stroke, and have been constructed by Messrs. Geo. Clark, Limited, Southwick.

FOREIGN TELEGRAPHIC ADVICES.

As we had to publish earlier than usual this week on account of the Easter holidays we were obliged to go to press without the latest telegraphic despatches from our Continental correspondents.

Digitized by Google

HOME INDUSTRIES.

LONDON, 3rd April, 1890.

THE MONEY MARKET.—Money has been in strong demand all the week. The necessity for tiding over the holidays has given rise to applications for accommodation which have exceeded the capacity of Lombard Street to supply. The Bank of England has been largely borrowed from, and rates have been well sustained at 3½ per cent. and over. Extensive purchases of gold for Germany have not caused any alarm, as enough has been forthcoming to provide for them, and at the same time to reinforce the bullion in the Bank of England. Discount rates have consequently been easier, and allotments of Treasury Bills at low rates have given the key to this market. A renewed firmness in silver has been observable. The stock markets have been pervaded with a holiday tone all the week; business has been limited, and prices well sustained. The spell of good weather has strengthened home railway stocks. Foreign securities, after a depression produced by fears of trouble on the Berlin Bourse at the settlement at the end of the month, improved when these fears were seen to be exaggerated, if not groundless. The American railway market is uncertain in tone in the absence of any controlling influence in one direction or another. Grand Trunk and Mexican Railway stocks are rather in disfavour. The panic in South African gold shares has ceased, but, though prices show a disposition to re-act slightly, there is no sustained recovery. Nitrate shares are not in request. There is no feature to note in industrial and miscellaneous securities.

COMPANIES.—The following companies have been registered since our last report:—Samuel Webster & Sons, Ld., with a capital of £175,000, to carry on the business of brewers; The Ship "Penrhyn Castle" Co., with a capital of £16,600; The Haswell Gaslight and Coke Co., Ld., with a capital of £5,000; The Ryecroft Mills Co., Ld., with a capital of £50,000, to carry on a business of cotton spinners at Ashton-under-Lyne; William Pearce, Ld., with a capital of £40,000, to carry on business as lead and glass merchants; Fuller's Earth Union, Ld., with a capital of £100,000; Swansea United Breweries, Ld., with a capital of £50,000; The Lightwood Colliery Co., Ld., with a capital of £20,000; The Temple Normanton Colliery Co., Ld., with a capital of £16,000; The Electric Meter Co., Ld., with a capital of £50,000; The East Halkyn Mining Co., Ld., with a capital of £15,000; The Simplex Brake Co., Ld., with a capital of £5,000; Read, Holliday, & Sons, Ld., with a capital of £200,000, to carry on the business of Read, Holliday, & Sons, as chemical manufacturers, &c; Adnams & Co., Ld., with a capital of £35,000, to carry on business as brewers; The Bear Creek Oil and Shipping Co., Ld., with a capital of £50,000; The Anglo-Continental Coal Co., Ld., with a capital of £10,000; The St. George's Ironworks, Ld., with a capital of £5,000; The Atacama Mineral Co., with a capital of £30,000; The Caledonian (Transvaal) Gold Mining and Prospecting Co., Ld., with a capital of £80,000; Hitchman & Co., Ld., with a capital £50,000, to carry on business as brewers; The Springfield Breweries Co., Ld., with a capital of £105,000; The Carmarthen United Breweries Co., Ld., with a capital of £50,000; The Bennett Steamship Co., Ld., with a capital of £100,000; The Damaraland Mining Co., Ld., with a capital of £100,000.

SHIPPING.—During the last fortnight freights have ruled low, and there has been a decline in many instances. There is a discouraging outlook all round. Mediterranean and Baltic business is very poor. From America a fair trade has been done, but the rates are falling slowly. The prices of new steamers are lower, but are still beyond the earning power valuation. Builders are becoming anxious about their orders, but their prices are still too high for prospective owners.

POLICE SIGNALLING.—We have received a pamphlet on Morgan's automatic electric signalling system, by Mr. Ernest de Vere Hill. This is a very complete system of telegraphic communication between the central office and the police on duty. Certain lamp posts, say one in each street, are fitted up so that the police, who have keys, can communicate with the station, and the station can signal for the nearest policeman and communicate with him. The public can also call for police or signal any message to headquarters.

THE GUILD AND SCHOOL OF HANDICRAFT.—The following is the list of Easter free lectures to be delivered at the workshop of the Guild School of Handicraft, 34, Commercial Street, London, E.:—April 3rd, 8 p.m., Mr. Henry Holiday, on "Looking Backward, in its Relation to Life, Taste, and Art;" April 10th, 8 p.m., Mr. T. Cobden Sanderson, on "Bookbinding;" April 17th, 8 p.m., Mr. W. B. Richmond, A.R.A., on "Gesso;" April 24th, 8 p.m., Mr. Sterling Lee, on "A Talk on Sculpture," with practical illustrations; May 1st, 8 p.m., Mr. E. Prioleau Warren, on "Parlour Architecture." Evening classes will be held as follows:—Carpentry, Tuesday, 8 p.m.; Decoration (men), Wednesday, 8 p.m.; Decoration (boys), Thursday, 7.30 p.m.; Clay Modelling and Wood Carving, Thursday, 8 p.m.; Repoussé Metal Work and Clay Modelling, Friday, 8 p.m.; Ruskin Reading Class, Thursday, 8.30 p.m.; Teachers' Carpentry Class, Wednesday, 6 p.m.

A NEW METHOD OF MOUNTING GUNS.—A successful trial of Sir W. G. Armstrong, Mitchell, & Co.'s new mode of mounting guns to be fired *en barbette* took place on Saturday, off the Isle of Wight, on board Her Majesty's screw gunboat "Handy," a vessel specially appropriated for gun trials. Particular importance attached to the proceedings on this occasion, the invention to be tested being designed to meet a defect which has been much felt in regard to the existing method of mounting heavy guns in barbette ships. Several novel features accompany the main design, the total result being practically a new departure in naval gunnery. The gun not only returns automatically into the firing position after each discharge, according to the Vavasseur recoil system, but is capable of being elevated so as to fire at angles up to forty degrees, or double that allowed by any previous mountings for such a gun, the calibre of the piece in this instance being 9·2in., and the weight 22 tons. The carriage on which the gun is mounted is also fitted with a steel shield, 6in. thick, which is attached to the mounting, and trains with it. The construction is such that the port through which the gun fires is completely filled by the gun at all angles of elevation, thus preventing the entry of projectiles or splinters. The mounting is intended for use in barbette batteries on the upper deck, and no similar carriage has hitherto been provided with any shield or screen capable of resisting the fire of anything more than machine guns, whereas the shield now devised will effectually protect the gun and gunners from all rapid-firing guns at present in use in the Service. The elevated fire is valuable as affording the means of attacking coast batteries placed on high ground at short range. At present elevated land batteries protecting a narrow passage or a harbour can fire down on ships attempting to pass them without being open to attack themselves. At the trial which took place on Saturday fifteen rounds were fired at angles ranging up to the maximum of forty degrees with perfect success in every respect.

MANCHESTER, 3rd April, 1890.

THE FOURNESS REGENERATIVE LAMP.—The Fourness Regenerative Lamp Company have acquired the business lately carried on by the Fourness Regenerative Lamp Company, Limited, at Pritchard Street, Oxford Street, Manchester, and are now prepared to execute orders for these well-known lamps. The business will be carried on at the above address by the new company, who have had a large experience in this class of gas lamps.

OPENING OF THE DEE RAILWAY.—The new line of railway extending from Chester, via the Dee Bridge, to a junction with the Wrexham, Mold, and Connah's Quay Railway was opened for traffic on the 31st ult. This route brings the coal fields of the Wrexham district into better communication with Lancashire and Yorkshire.

THE TECHNICAL INSTRUCTION ACT.—The Special Committee of the Manchester City Council has presented a report with reference to the Technical Instruction Act. They recommend its immediate adoption as being readily applicable to the wants of the city, and also recommend their reappointment as a special committee to carry it into effect.

ELECTRIC LIGHTING.—A number of circulars have been issued to various firms in Bolton asking them to express their willingness or otherwise to adopt the electric light. 1,178 inquiries were sent out, of which 449 brought out replies, 45 of these being favourable, and 80 of a doubtful character. The Town Clerk is applying for powers, but this is intended more to protect the interests of the Corporation than with a view of immediate action.

THE THIRLMERE WATER WORKS.—A tunnel, 3,040 yards long, through Moor How hill, has been successfully pierced. This forms part of the aqueduct in connection with this water scheme. It is pierced almost entirely through hard rock, and has taken nearly four years to construct. The contracts for the remainder of the work are now making satisfactory progress, and the laying of the pipes is being proceeded with in some of the sections.

COTTON MILL DIVIDENDS.—During the month of March forty-two mills in the Oldham district have published the results of the quarterly stocktakings. They comprise 2,800,000 spindles, and have made a gross profit during three months' working of £61,346, which has yielded an average dividend of 8 per cent. Spinners do not anticipate a continuance of these good results unless the condition of manufacturers improves, as they are now badly placed for remunerative business.

THE ENGINEERING TRADES.—The general condition of these trades, although satisfactory so far as old orders are concerned, is not quite so good in the amount of new business coming forward. There is a perceptible lull in the advance of orders in almost all departments at present, but there are indications that it is only temporary. Boiler makers perhaps are less troubled than others. Machine makers are not obtaining anything like so much new business, and are in some cases becoming anxious. There is a strike of moulders in Bolton, and it is rather disturbing that district.

THE LINEN AND JUTE TRADES.—The reduced lists issued about the last week in February by manufacturers of fine makes of linens have not improved business, and there is very little doing at the present time. Coarse makes are cheaper, and the fall in Dunfermline goods ranges from 4 to 5 per cent. Tows being weaker in proportion than line yarns, the drop in articles made from the former is greater. The shipping demand is rather quiet, but some buyers from the States arrived on the "City of Paris," and more activity in our market is therefore anticipated. Business with American houses in the future will, it is feared, be curtailed considerably, owing to the oppressive restrictions of the McKinley Tariff Bill, which empowers the Customs officials to fine or imprison importers, without trial by jury, for what they may consider under-valuation. The rate on brown and bleached linens, ducks, canvas, and handkerchiefs is to stand at 50 per cent. *ad valorem;* on linen (or part linen) collars and cuffs, 30 cents per dozen, and 35 per cent. *ad val.* Hessians are a shade weaker, but not sufficiently so to result in any appreciable change in quotations. The home trade, as previously indicated, is generally quiet. There is a prospect of a more extensive distribution ere long, however, not only in linens, but in all descriptions of dry goods, and the settlement this week of the Liverpool dock strike has already given a fillip to the vast shipping trade of the city. The business passing in German and French specialties is of an average character. Owing to the practice on the part of foreign manufacturers of selling to the retail as well as the wholesale, it is not easy to trace with accuracy the extent of this trade, which is chiefly in goods of the expensive class.

GLASGOW, 3rd April, 1890.

ENGINEERING.—The locomotive works in Glasgow are well employed. Messrs. Dubs & Co. are extremely busy, and Messrs. Sharp, Stewart, & Co. have orders to keep them going for many months ahead.

SHIPBUILDING.—An order, which is understood to have come through a London firm, has been placed with Messrs. Lobnitz & Co., Renfrew, for three large dredgers. Some of the smaller shipbuilding yards on the Clyde, having got to the end of their orders, are beginning to feel the pinch of hard times. Inquiries are very scarce.

ELEVATING FERRIES.—The elevating ferry which is now being constructed for the Clyde Trust will soon be in its place. The Works Committee of the Trust have been instructed to make provision on either side of the river for the reception of the ferry steamer. Some modifications on the original plans for the "dolphins" have been made, the design being that these should interfere as little as possible with the shipping.

SCOTTISH RAILWAYS.—Although there is an impression that business is not so brisk as it was, the railway traffic returns show that the volume of goods passing over the lines is increasing rather than diminishing. The first three months of 1889 showed large increases over the corresponding months of the previous year; and now the returns for January till March, 1890, show quite a remarkable increase over these figures. The absence of any serious labour troubles and the working off of orders placed some months ago are the proximate causes of this result. The fall in Scottish Railway stock, especially in Caledonian, has occurred in spite of this increase of traffic, and has been due to assumed uncertainty as to the Conversion Bill now before Parliament, and to speculative over-buying.

GLASGOW COMPANIES.—The directors of the Pollok Patents Gold Extracting Company have announced the distribution of a bonus of 2s. 6d. per share (5s. paid), payable on the 8th inst. This bonus is available owing to the successful floating of the Australasian Company under the wing of the Pollok Company. The shares of the new company formed by the amalgamation of A. & J. Stewart, Limited, and the Clydesdale Iron Company are already at a premium of about 12s.

(From our own Correspondents.)

LIVERPOOL, 2nd April, 1890.

LIVERPOOL ENGINEERS.—It was feared that the strike which took place among the engineers at Tyneside would extend to Liverpool. The Amalgamated Society of Engineers demanded a short time ago an advance of 2s. per week for Union men working in Liverpool and the district. The General Association of Master Engineers have intimated through the secretary that they are willing to pay the advance on and after the 10th July.

THE DOCK STRIKE.—This unfortunate strike of the dock labourers has now happily terminated, and work is resumed along the whole line of docks. The reconciliation has been effected by the able, impartial, and practical mediation of Mr. Michael Davitt. He at once grasped the situation, and, instead of hurling abusive invectives at the shipowners, he calmly approached both masters and men and obtained concessions on both sides, and the strike is now ended. The conditions agreed upon through his intercession are: (1) A regular dinner hour from 12 to 1, and if the men work during this hour they are to have an extra hour's pay; (2) the men need not work more than nine hours at night, all beyond this time being paid as overtime at a special rate; (3) union and non-union men to work harmoniously together; (4) weekly labour to be offered to the men, with a week's notice on either side, the men to deposit a week's wages by instalments; 5) the men on strike to be taken back as they are required and are not to wear their badges in working hours; (6) the union not to boycott Liverpool ships in other ports.

SHEFFIELD, 2nd April, 1890.

THE COAL AND COKE TRADES.—Business continues to be fairly good, although by no means brisk. One of the main reasons for the quieter tone is that the heaviest consumers of coal and coke had laid in a good stock of fuel, which is not yet exhausted. Prices are firm, although the production is evidently overtaking the demand, and they cannot continue long as they are. House coal is quoted at 14s. to 16s.; slack, 6s. to 7s.; smudge, 4s. to 6s. There is a

Digitized by Google

good demand for coke; best qualities are in special request for steel melting. With a view to economise steam-raising fuel several firms here are adopting special feeding apparatus to their boilers. A mixture of 25 per cent. of coke with smudge, machine-fed into the furnaces, has given every satisfaction.

THE IRON AND STEEL TRADES.—The iron market is rather unsteady, owing in a great measure to the results of speculation in the North and North-East of England. In steel there is no perceptible reduction in the output, and work goes on steadily night and day. A new works has been started by Messrs. Hampton & Facer, for the purpose of working out a new system of ingot casting. The products of the works will be of best quality, of all sizes, and chemical compositions. Mr. Hampton has been well-known both in connection with Messrs. Davey Brothers, and afterwards with Messrs. Steel, Peach, & Tozer, Phœnix Bessemer Works, Rotherham.

ENGINEERING.—So far the threatened dispute about the 2s. advance to turners, fitters, and machine men generally, has been settled satisfactorily; all the leading firms have granted the advance, and the others are not likely to cause much trouble.

NORTH STAFFORDSHIRE, 2ND APRIL, 1890.

THE IRON TRADE.—It would be affectation to disguise the fact that manufacturers begin to recognise a complete collapse of the revival in trade which originated only twelve months ago. Inquiries and orders are in the nature of exceptions in the morning's budget, and consumers who are in the market are resuming the attitude of the last decade. How finished iron producers will fare for the next three months is a puzzle for themselves. The sliding scale gives their workmen an advance of 7½ per cent. from last Monday, coal is dearer owing to the advance in colliers' wages, and prices are falling enormously. In some cases heavy sales forward at remunerative figures have been entered, but in others anticipation of higher prices have made producers over cautious, and in such instances books are getting bare of orders.

THE COAL TRADE.—Prices for coals for domestic consumption have advanced in consequence of the rise in colliers' wages, but the demand for manufacturing fuel shows signs of diminution, and there is some weakness becoming apparent in the matter of prices.

LEICESTER, 2ND APRIL, 1890.

WOOL SPINNING AND YARN TRADES.—No great change has marked the wool market during the last fortnight. There is a tendency to increased firmness in prices, and as the stocks are light, especially of the choicer growths of wool, this firmness will continue. The business done has been very limited, and users are buying very cautiously. The spinning trade is not satisfactory; new business does not come to hand very freely, as buyers are waiting for the prices to become settled. As the conditions of the mills vary so much the quotations are irregular. Yarn merchants are having a quiet time just now.

HOSIERY TRADE.—This industry opens slowly. Generally the condition of trade is considered healthy, but the demand on the producing powers of the machinery is light. It is the current opinion that the trade will soon revive. Some of the causes of this inactivity are the heavy production of last year and the uncertainty of feeling with regard to the yarn market. The latter cause much affects the yarn merchants, and is the cause of their restricted turnover.

BOOT AND SHOE TRADE.—A busy time has lately prevailed, and it has culminated this week in the endeavour to fill orders on hand before the holidays. The demand has taxed the machinery, and the general complaint lately has been the scarcity of labour. Leather merchants are not doing much, despite the activity in the manufacturing department. Consumers are using up stocks, and as the condition of the market offers no inducement to buy they only purchase for very immediate wants.

SWANSEA, 2ND APRIL, 1890.

TINPLATES.—A decided check to the downward course of prices has been given by the recent "stop-week," and buyers are coming forward with more reasonable views than have prevailed for some time past. The completion of old contracts for steel bars at low prices is also having a natural effect on the supply of low-priced tinplates, and if masters and men could only continue to work amicably together the trade might soon recover from the effects of the recent depression. Unfortunately the air is full of rumours that threaten another crisis at no distant date. The proposal of the Manufacturers' Association to "revise" the standard of 1877, which still governs the rate of wages, has been met in the most determined manner by the men's union, who interpret the intended "revision" to mean a "reduction," and at their behest notices to terminate contracts are to be sent in at the earliest possible moment. A strike has also been going on at the Melingriffith Works, due to the endeavour of the company to lower the standard of Canada plates, which the men will not work at anything except 54 sheets per box. The owners of the most important works that carried on operations during the recent stop-week have decided to have one of their own later on. 350 mills out of a possible 450 were idle during the first week in March.

GOLD MINING IN WALES.—It seems reasonable for Mr. Pritchard Morgan to complain that, after spending £140,000 in developing the industry of gold mining in Wales, such delay should occur before trying the Crown injunction by which his company has been prevented from continuing operations since 1888. He urges that the subjects of the Crown are freely allowed, nay, encouraged, to drive for gold and silver in every other part of her Majesty's possessions except in Great Britain, where royalties are claimed on the gross production, whether obtained at a loss or at a profit. It is interesting to note that the mine in question has already produced gold to the value of £50,000, and that this precious metal and silver in the United Kingdom are for the most part to be found in Wales and Ireland.

NAKED LIGHTS IN MINES.—The protest of the Cwmbran colliers against the recommendation of her Majesty's inspector of mines that locked lamps should be used in that colliery renders the action of the management a difficult one. The men say that the introduction of lamps in place of naked lights would be an injustice, and would not add to their safety, but rather that increased loss of life from falls of roof and sides would follow.

NEW PATENT FUEL WORKS.—Detailed plans have been approved by the directors of the Barry Dock and Railways for the construction of an extensive patent fuel works at Barry Dock.

CARDIFF, 2ND APRIL, 1890.

IRON AND STEEL.—The pig iron market has shown a further weakness in consequence of the unexpected drop in warrants, caused chiefly by the inability of large owners to hold out any longer. Notwithstanding this, stocks are decreasing, which is a sure indication that ironmasters are reliable when they profess to be well sold forward at high prices. Certain it is that if ironmakers had to buy raw material, coal, coke, iron ore, &c., at to-day's prices, and sell also at to-day's figures, they would be clear losers of 15s. per ton. It is inevitable that things must adjust themselves soon, or trade will be completely paralysed. Coal is certainly the last thing that low iron prices will influence as far as South Wales is concerned, as the value is influenced entirely by the foreign inquiry, which at present seems to be stronger than ever. Coke cannot be brought down as long as coal rules so high, and from recent accounts from Spain, whence the bulk of hematite ore is drawn, the price seems to be still advancing on account of the abnormally high demand. At Portugalete, one of the principal loading places in the Bilbao River, steamers have to wait in turn about ten days before the loading can be commenced. Rubio ore is quoted at 10s. to 10s. 6d. f.o.b. Bilbao, which, with the freight, makes its value 16s. to 16s. 6d. c.i.f. Cardiff or Newport. Steel tin bars are nominally quoted at £7 5s. to £7 10s., but no business of importance has been done at these figures, both sellers and buyers preferring to wait the issue of the quarterly meetings next week.

COAL AND COKE.—The arrivals of tonnage during the past few days have been exceedingly numerous, and in consequence there is a decidedly firm tone noticeable in the steam coal trade. The demand for the coaling depôts in the Mediterranean is not quite so heavy on account of the poor prospects for the Black Sea business during the approaching season, but, with this exception, there is a steady influx of orders and inquiries from all other directions. Large steam is quoted at: 16s. 3d. to 16s. 9d., first quality; 15s. 6d. to 16s., second quality; 14s. 9d. to 15s., third quality; 14s. 3d. to 14s. 9d., inferior quality. There is less excitement in the market for small steam, which, however, is still quoted firm at 9s. 9d. to 10s. 3d. House coal is steady. New orders for coke are infinitesimal, but, having substantial contracts to carry out, makers have made no reduction in their prices.

BARROW-IN-FURNESS, 2ND APRIL, 1890.

DEPRESSION IN HEMATITE IRON.—An unexpected depression has set in in the hematite pig iron trade, and prices have dropped fully 6s. per ton on the week. Makers of hematite have been doing no new business of late, as they have been quoting all along fully 10s. per ton above the price at which buyers could obtain warrant iron. This is one of the effects of overstocking. Makers are not only about to restrict the output of pig iron at their works by the further blowing out of furnaces, but it is reported on good authority that they intend to buy largely of warrants, as a cheaper means of making steel than is at the command of smelters.

STOPPAGE OF THE MOSS BAY IRON AND STEEL WORKS.—Owing to financial difficulties and the impossibility of making a profit at present prices the managing director and the secretary of the company issued circulars to the shareholders on Monday morning, saying it would be necessary to stop the works and damp down the furnaces. The men were acquainted with the decision of the management when they went to work on Monday morning.

STEEL.—There is a quiet tone in the steel trade. Orders are coming to hand very slowly, and there is not much disposition on the part of buyers to place contracts at present. It is indeed probable that makers will soon be wanting orders, and that buyers will be able to place forward contracts at cheaper prices; but in the meantime, with iron ore, coke, and labour at present prices, makers cannot possibly hope to make steel at lower prices than they have been quoting. Heavy rails are 5 15s. to £6 per ton, steel plates at £8, and angles at £7 10s. per ton net f.o.b.

IRON ORE.—There is an easier tone in the iron ore trade, but prices remain firm at 13s. 6d. to 17s. per ton net at mines.

MIDDLESBROUGH, 2ND APRIL, 1890.

PIG IRON.—There was a very meagre attendance on 'Change at the weekly market held yesterday, and no great disposition to do business was shown. Prices have fallen 3s. since last week, and buyers are waiting for still lower prices. Sellers are asking 49s. 6d. for No. 3 G.M.B. prompt delivery. Warrants are quoted at from 49s. to 49s. 6d. There is a great drain upon the public stores, as the makers are holding to their prices. In hematite East Coast brands are quoted at 75s. per ton for mixed numbers makers' iron, but 70s. has been taken. West Coast hematite has fallen to 58s. 7d., on account of the Moss Bay failure, which will place their stock upon the market. The stock in Connal's store on the last day of March amounted to 151,288 tons, as against 161,060 tons a week back, showing a decrease over the week of 9,772 tons.

SHIPMENTS OF PIG IRON.—The shipments are improving as compared with February, but are far behind those of March of last year. For the month of March this year they amount to 60,683 tons, as against 87,314 tons during March last year. Of the 60,683 tons, 16,986 went coastwise, as against 53,420 last year, and 43,697 went abroad, as against 33,894 last year. The fall in coastwise shipments is, of course, accounted for by the fall of Scotch prices to the level of Cleveland.

MANUFACTURED IRON AND STEEL.—Both iron and steel are tending to dulness. The works are busy, but new orders are not coming in fast enough to take the place of the old which are being worked off. Prices are lower. Iron ship plates are at £6 12s. 6d., angles £6 12s. 6d., bars £6 15s. per ton; steel ship plates £7 12s. 6d., angles £7 12s. 6d., rails £5 17s. 6d. per ton, all less the usual discount. The exports of manufactured iron for the month of March are nearly 10,000 tons in advance of those of last March. The steel exports are less.

PURCHASE OF IRON WORKS.—Under the direction of the Court of Chancery, the West Stockton Ironworks have been sold as a going concern to the British General Investment Trust, Limited, at the price of £75,000. These works have been kept steadily going for some years, and are likely to be a very profitable investment.

NEWCASTLE, 2ND APRIL, 1890.

THE IRON TRADE.—Quietude is still the prevailing feature in the iron trade, and, though manufacturers of the finished material are still kept busy, a less satisfactory state of matters must soon be experienced unless new orders are received to replace those that are now being worked up. Buyers, however, are loth to operate, the expectation of a further fall in prices being no doubt the main cause of their hesitancy. The demand for thin sheets, though not so brisk as it was a year ago, is still sufficient to keep the mills engaged in the manufacture fully employed. In the galvanising works there is a good business doing.

STEEL WORKS.—Orders are still very plentiful at the steel works of Messrs. John Spencer & Sons, Newburn, much of the work in hand being for railway service in different parts of the country. The new steel plate mills are rapidly approaching completion. The steel works of the Palmer's Company at Jarrow are quite exceptionally busy, the company's own requirements for shipbuilding and boiler making purposes being at this moment unusually heavy.

ENGINEERING.—Messrs. John Abbott & Co, Gateshead, have several large colonial orders for hydraulic machinery in progress, and their works are consequently very busy. The marine engine department of Messrs. Black & Hawthorn's works is kept briskly going, there being several sets of engines in hand for vessels building on the Tyne and Wear. Messrs. Allen & Robson, the agents in Newcastle for Purves' patent ribbed furnaces, are doing a large business in this line, one of the most important orders lately supplied by them being 24 of these furnaces for the boilers of the Russian passenger steamer "Orel," built and engined by Messrs. Hawthorn, Leslie, & Co. This firm (Messrs. Allen & Robson) have just taken up the agency for a new "sure-grip tackle block," the principal feature of which is that rope is used as the suspensory medium, instead of chain. It seems to be a decided improvement on the descriptions of safety hoisting blocks at present in use, and should soon command a large sale.

ELECTRIC LIGHTING.—The new wing which has been added to the electric lighting works of Messrs. J. H. Holmes & Co., at Stepney, having been fitted up with effective machinery, is now in full operation, and forms, in conjunction with the older works, one of the largest and best-appointed electric light engineering establishments in the kingdom. The firm have orders for over twenty steamship installations, besides a number of land installations, the total number of dynamos now in progress or on order being no less than one hundred and fifty. Among these are several coupled on the direct system with single and compound engines, which arrangement is understood to combine many advantages. Among the most important orders lately received by the firm is one for a 2,000-light installation in a South American meat factory.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 4TH APRIL, 1890.

THE INSTITUTION OF NAVAL ARCHITECTS.

IT is now thirty years since the Institution of Naval Architects was founded, and in looking over the range of "Transactions" which it has published, and examining their contents, we can say that it has fully justified its existence. We think that few Institutions can show such a high standard in the papers which have been read before it, containing as they do, not only an account of all that is best in current practice, but also of investigations which led to developments in that practice. The meeting at which the Institution was established was held on the evening of the 16th of January, 1860, in the Hall in which the members have always met since, that of the Society of Arts. About forty gentlemen were invited to attend, but as many resided in remote parts of the country, and as others had official duties to perform at considerable distances from town, a large attendance was not anticipated. On looking over the roll we find that eighteen attended, a great many of whom have now passed over to the majority. Mr. (now Sir) E. J. Reed was the first Secretary, and gave an introductory and explanatory statement of the objects of the Institution. He stated that the want of an Institution which should have for its exclusive aim the improvement of ships, and of all that specially appertains to them, had long been felt by many professional men, but that previous attempts had always ended in failure. At that time, however, the state of the Navy was the subject of much anxiety to the public, and it was felt that if the establishment of such an Institution was ever to be effected that was the right time to set about it; the matter was therefore again revived, and the Institution of Naval Architects safely launched, and it has ever since continued to increase in prosperity. Its list of members contains the names of all the most distinguished naval architects and marine engineers in this country, and many of those of other countries, while among its associates are many who have taken a prominent place among those interested in naval and shipping matters. Mr. Reed pointed out the necessity for the Institution not only directing its attention to the improvement of ships, but also to all that specially appertains to them. He said no Institution having for its object only the improvement in the forms of ships, or of the actual building of ships, or of the fittings of ships, or indeed of any single branch of the naval architect's study, could ever be successful; because, in the first place, there was not a sufficient number of persons to constitute an effective institution engaged in any one branch; and secondly, because no single feature or portion of a ship could be properly studied apart from others. Hence it was seen that the scope of the Institution must of necessity be wide enough to embrace the consideration of all that is part of or belongs specially to a ship. While it was considered proper to so far recognise the naval architects—to whom alone the ship, as a great complex whole, is a subject of study—in giving their distinctive name to the Institution, it was felt that, if it was to be a vital and vitalising body, it must draw into association with itself persons from all the classes connected with ships, and especially shipbuilders, men of science, seamen, engineers, mastmakers, riggers, smiths, and others. At first only naval architects proper were admitted as members, and all the others as associates; but it was soon found that marine engineers were worthy of the position of full membership, and now they form a very important part of the Institution—in fact, as some of the naval architects complained at recent meetings, they seemed to monopolise more than a fair share of the time.

The broad basis on which the Institution was founded ensured its success and brought to its meetings men whose papers and discussions form a mine of study to the student of naval architecture. During the first half of its existence the Transactions of the Institution were enriched with many papers which are now among the classics of the subject. The very first volume, for instance, contained an admirable *résumé* of the state of the mathematical theory of Naval Architecture at the time by Dr. Woolley, and thus afforded the members a good starting point for their discussions. In it also John Scott Russell gave an account of his Wave Line Principle of Ship Construction, which even now is worthy of careful study. Professor Airy discoursed on the correction of Compasses in Iron Ships, while Mr. Barnes began his series of papers on different subjects connected with naval architecture with which he enriched the Transactions. It would be invidious, even if it were possible, in our limited space to give a list of all those whose papers we considered specially worthy of notice, but there are two whose names we cannot pass over—we mean Professor Rankine and William Froude, whose mathematical and experimental investigations make the early volumes of the Transactions invaluable. During recent years, although there has not been anything very distinctive, the papers have embraced a wider field, and almost every part of naval architecture and marine engineering has received attention.

The meeting of the Institution which was held last week, we are afraid, had scarcely a programme which came up to the high average of preceding years, not only as regards quantity, but also quality. This may be accounted for by the extremely busy state of trade during last year, which may have prevented members from putting on paper the results either of their study or experience. As we mentioned in our report of the meeting last week, the President stated that the characteristics of the work of last year had been large production but moderate profits, while the proportion of vessels built of iron had gone down to 8 per cent. He condemned the Load Line Bill, but, as we have already pointed out (see *Industries* of the 7th ult.), it is possible to make provisions which will prevent the evils which he anticipates, and we understand that those in charge of the Bill have been able to meet almost all possible objections. We are strongly of opinion that nothing should be done which handicaps British shipping, but we also think that it is unnecessary to do this in order to protect the lives of seamen. The most important paper read before the meeting was undoubtedly that by Mr. White, the Director of Naval Construction, in which he gave some "Notes on the Recent Naval Manœuvres." As this bears to a considerable extent upon our leading article of last week, we will make a few remarks upon it. The opening sentence of Mr. White's paper confirms our opinion of the general character of the programme, for he states that it

Digitized by Google

was written at the request of the Council, because they found themselves less favourably placed than in former years in relation to papers offered for reading and discussion, and they had urgently asked him to contribute to the programme of the meetings. We hope that the members will take a note of this, and in future make it unnecessary for the Council to hunt for papers. Mr. White, in his capacity of Naval Constructor, had been requested by the First Lord of the Admiralty to go afloat last August, and to remain with the fleet during the manœuvres. He had thus excellent opportunities for observing the operations of mimic warfare and fleet manœuvring, especially as the weather was bad during a good part of the time, and it is pleasant to find that, on the whole, his observations are to be read with satisfaction. We have given in another place a *résumé* of his paper, and therefore need only mention a few of his most important conclusions. On the subject of the influence of size and weight upon the sea-going qualities of ships, he differed entirely from the opinions which were expressed by Sir N. Barnaby before the Institution of Civil Engineers last year, and he said he was confirmed in his views by those of the majority of the naval officers with whom he had consulted. Sir Nathaniel had said that he agreed with those naval officers who thought it did not much matter as regards fighting qualities whether a ship was 3,200 tons or 14,000 tons, for the weather that would render it impossible to fight with the one would do the same with the other. Mr. White states that even the limited experience of the recent manœuvres proves that, for fighting in a seaway, ships of 3,000 tons and upwards are not practically on an equal footing. The possibility of any ship continuing to fight and maintaining good speed depends largely upon her length and size, as well as on her freeboard and the disposition of her armament. For instance, the vessels of the "Medea" class proved good sea boats, but it was obvious when they were seen in rough weather alongside a belted cruiser of 5,600 tons, or the "Warspite" of 8,400 tons, that these latter had very superior powers of maintaining speed and fighting because of their greater size and weight, while, if one of these latter had been alongside of one of the new battle-ships of 14,000 tons, Mr. White thinks that her advantages relatively to the "Warspite" would probably have been no less marked. With regard to the speed, Mr. White said it had been proposed that war cruisers should be built equalling the Atlantic "greyhounds" in speed and coal endurance, but surpassing them in armament and protection. To do this must involve still greater displacement and cost, and Mr. White is of opinion that we may well hesitate in embarking on such a course, so long as we possess, not merely a vast superiority in swift merchant steamers available as auxiliaries to the regular fleet, but also larger war cruisers than are to be found in foreign navies. Mr. White discussed at length the influence of freeboard, height of guns above water, and disposition of armament upon fighting qualities at sea. We must refer to the paper for details, but, speaking broadly, the recent manœuvres confirm the conclusion generally reached beforehand—namely, that low freeboard forward puts a practical limit upon the power of driving ships against a head sea, while it entails a sensible increase in the expenditure of power required to maintain a given speed in a moderate sea, as compared with the expenditure in high-ended ships of similar form and equal size.

The lessons derived from the manœuvres have led to certain alterations, or rather additions, in certain classes of ships—such as improved ventilation in engine and boiler rooms, greater facilities for intercommunication between engine rooms and boiler rooms, and improved arrangements for the transport of coal from the upper bunkers to the fires in ships. It is very satisfactory to find Mr. White stating that there is no foundation whatever in any of the reports about structural weakness in some of the ships engaged in the manœuvres. The contradiction of such reports can only be done by the publication of such information as is found in Mr. White's paper, and the discussion of it before such a body as the Institution of Naval Architects, and we trust that Mr. White will be encouraged by the Admiralty to continue the custom which he has introduced. It would also save the officials of the Admiralty from a considerable amount of correspondence and unfair criticism. The recent letter of Lord Randolph Churchill to one of our daily contemporaries is an illustration of what we mean. His lordship thought he had discovered a piece of official blundering and red tape about the purchase of certain boiler tubes, and immediately he wrote a letter to the daily papers. Mr. Forwood, the Parliamentary Secretary to the Admiralty, replied, explaining the actual facts, and proved that his lordship had depended too much on the information of a naval officer, which is too often apt to be indefinite and sometimes exaggerated. We need not enter into the details of the case, and only mention it to show the desirability of correct information being furnished on all points about which there is likely to be any discussion. We can imagine subjects on which the Admiralty may consider it proper to keep their own counsel, but in matters which refer to the science and art of engineering or ship-building it is highly advisable that they should aid the professors of shipbuilding with all the information at their command.

THE OPENING UP OF WESTERN CHINA.

A SPECIAL meeting of the Glasgow Chamber of Commerce was held on Wednesday in last week for the purpose of hearing an address by Mr. Archibald Little, F.R.G.S., on "The Upper Yangtse and the Opening of Western China." As Mr. Little is possibly better acquainted with that part of the world than any other British subject, a few of his most important remarks will be of interest to our readers.

After explaining something of the geography of the district, and of the history of its relations to western countries till the time of the Chefoo Convention, Mr. Little explained that the province chiefly affected by that treaty was Szchuen, which was in extent about double the size of Great Britain and Ireland, and whose population was estimated at 50 or 60 millions, this population being, according to the accounts of travellers and his own experience, the most prosperous in China. The great question was how to reach this magnificent country and exchange goods with it by the most economical and shortest route. Three main routes were proposed. There was the short cut by Bhamo to Yunnunfoo, 350 miles by an air line or 967 miles by road, over mountains and ravines, with total ascents equal to 26,000ft. Then Mr. Holt Hallett had shown an admirable route for a railway from Moulmein, but it would be long before it was carried out, whereas by the Yangtse the approach was practical and simple, and, notwithstanding the long length of rapids, boats with heavy machinery were towed up successfully. A very large native trade went on by land routes from different districts, and the goods were carried chiefly by coolies and pack-horses. Since the French got to Tonkin they had tried to open another route, and last year a stern-wheeler 105ft. long succeeded in going to Laokin from Hanoi in eight steaming days; but this could only be done at the height of the freshets in July, and the river was scarcely navigable at any other time, whereas the Yangtse was navigable all the year round. The province of which Chun-King was the commercial centre was one of the most fertile in the world; it was like one vast garden, and was the only part of China Mr. Little had seen where the country was cultivated to the mountain tops. Within the past few years the Chinese had practically given up growing winter wheat, and had taken to the growing of the poppy, and now the production of native opium was very nearly equal to that imported. The chief exports from Szchuen were silk, silk piece goods, and silk waste. Two tons of musk were exported last year, and, in addition, spelter, copper, iron, and coal. Salt was the largest article of export, and its manufacture or preparation was entirely in the hands of a guild, similar to those which existed in Europe in the Middle Ages.

Szchuen was chiefly interesting to the merchants of this country as being unsuited to the growth of cotton, whereas the coast provinces of China produced large quantities of cotton. About one-tenth of the cotton goods, and one-fifth of the woollens, which came to Shanghai, went to Tchang, at the foot of the rapids, and thence found their way to Szchuen, and as Mr. Little remarked, when one found a country so rich, the people so well to do, so anxious to purchase products from outside, and having so much to exchange, one felt desirous to improve the means of communication. In the matter of railways, Mr. Little confirmed the opinions we have often expressed, that the Chinese seemed determined to carry on the work in their own way, with their own money, and by their own men. One of the most progressive Viceroys, who had lately been sent to the province of which Hankow was the centre, had said that before railways were built they must have Chinese iron. Iron must be got out of the mines, rails must be forged, machinery must be made, and everything must be done in China. Whether that would be the case ultimately, it was impossible to say at the present moment. Mr. Little then gave an account of the attempt which he had made to open up navigation, and of which we have given details on previous occasions. As we mentioned, the end of that attempt was the purchase of Mr. Little's steamer, and at present negotiations were being conducted between the Chinese and our Foreign Office for the opening of the port of Chun-King, provided we would not attempt the navigation of the Yangtse for a term of years, and in the meantime foreign subjects might reside at Chun-King; and, on the whole, this seemed a fair compromise, for at the end of the specified time trade would be largely developed. Mr. Little then gave some details of the mineral resources of China, especially of the province of Yunnun. The whole of the copper for the coinage of China, which was a copper coinage, was exported by land, and afterwards by water, down the Yangtse, so that there was not only an enormously rich agricultural country and an active and wealthy population, but almost inexhaustible mineral resources. The basin of Szchuen had been estimated as the largest coalfield in the world. Coal was entirely used by the people, but it was worked in a hand-to-mouth way. Gold was also found in considerable quantities, being washed from the sand brought down by the rivers in winter, showing that there must be very rich gold-bearing mountains.

Mr. Little explained that his chief object in addressing the Chamber was to beg of those interested in the foreign trade not to remain idle or apathetic, or to think that they had done enough for China. What they had to do was to get our Minister in China and our Foreign Office here to open up new markets. Step by step we had got nineteen ports opened in China, and when Chun-King was opened it would make the twentieth—another Shanghai. He believed the people were anxious to have the country opened up to trade. Whenever one passed the mountains nothing was more striking than the friendliness and kindness of the people. The officials did not care much for change, but the people had great weight with them, and we should exert ourselves and do all we could to aid them in opening up Western China to foreign trade.

CONDENSATION AND RE-EVAPORATION IN MARINE ENGINE CYLINDERS.

AT the last meeting of the Institution of Engineers and Shipbuilders in Scotland, a paper was read by Mr. Edward C. Peck, on the loss by condensation and re-evaporation in marine engine cylinders. The chief object of the paper was to consider a suggestion whereby the efficiency of marine engines might be increased without increasing expansion. The author pointed out that condensation and re-evaporation in the cylinders had long been recognised as a great source of loss, and it was generally held that, by breaking up the operation of expansion in two, three, or four cylinders, we had overcome the difficulty. This, he thought, was still doubtful. The action of the steam on the walls, cover, and piston of the cylinder had received very able investigation, but he thought that the ports, and what occurs within them, have not had their full share of attention. The conduction of heat into and out of a metal surface is dependent upon the rate of circulation of the heating or cooling medium over it, and this circulation is of greater moment as the difference of temperature between the two becomes less. Now, the steam passes into and out of the cylinder without actually circulating over its surfaces; the vapour in contact with the cylinder remains in contact, or at most cannot possibly pass over its surface at a greater speed than that due to the piston speed, while in the case of the ports the whole volume is passed through an area (which has generally a very large proportionate perimeter) at about ten times the piston speed. The circulation over the cylinder surfaces is practically *nil*, and conduction is further impeded by the condensed water clinging to them, but it is extremely rapid and efficient in the ports, where the high speed steam maintains the surfaces clear of water and makes them in the best state for parting with or taking up heat; better conditions, in fact, could hardly be obtained for promoting condensation and evaporation. While the cylinder walls probably do not rise much above or fall much below a certain mean temperature, each port gets thoroughly heated up to the initial and then thoroughly cooled down

Digitized by Google

to the terminal temperature at every revolution. Steam jacketing may do a great deal to lessen condensation and re-evaporation in the cylinder, but it obviously cannot deal with the serious mischief which thus occurs in the ports; it is in the latter where the heaviest losses occur. There can be no doubt that, especially in the quadruple expansion engine, where this heating or cooling action takes place sixteen times per revolution, we have a state of things which demands a remedy, and any successful attempt to eliminate it would be amply repaid by increased efficiency.

Mr. Peck pointed out that the high efficiency of the Corliss type of engine is probably not so much due to careful jacketing and the facility for obtaining a correct distribution as to the separate steam and exhaust ports adopted, and he suggests the adoption of separate steam and exhaust ports for marine engines. He is aware that there might be increased complication, and probably also greater first cost, but he thinks that the steam valves, link motion, and reversing gear would be at least 25 per cent. lighter. Moreover, in the adoption of separate valves there would be another direct advantage. In our present piston valves there is a constant leakage in each valve from steam to exhaust side to an extent proportionate to the size of the valve, which is at least one-third larger than that necessary for steam alone. In addition to this there is the constant loss by conduction through the thin body of the valve from steam to exhaust side. The greatest gain in efficiency, however, would be from the reduction of initial condensation and subsequent re-evaporation, and Mr. Peck thinks that this might be so great as to lead to the substitution of a two-cylinder compound for a triple, and at least postpone the further advance in complication involved in quadruple engines.

We think Mr. Peck's suggestions worthy of the consideration of marine engineers. We are not overlooking that in the early days of the Corliss valve gear it was applied to marine engines, but both that form of gear and many others have been much developed during recent years, and one might now be designed which would not only effect the chief object in view, but be also sufficiently simple to allow it to be applied to marine practice. The main feature in the engines shown in the recent Paris Exhibition was the great variety in the valve gears, and we think that if the matter were taken up in the direction suggested by Mr. Peck it might lead to good results. We shall be glad to have the experience and opinions of marine engineers on the subject.

Legal Proceedings.

MORGAN AND CO. *v.* WINDOVER AND CO.

The House of Lords, consisting of the Lord Chancellor, Lord Watson, Lord Herschell, and Lord Morris, gave judgment in this patent action on the 11th ult. in favour of Windover & Co. The patent of Morgan was dated in 1876, and the invention was for improvements in carriages. The Court of Appeal upheld his patent, as reported in *Industries*, Vol. III., p. 351.

The House of Lords reversed this decision, and declared the patent invalid on the ground of there being no "patentable invention."

The facts sufficiently appear from the judgment of Lord Watson, who said:—"At the date of the patent there were in common use three different arrangements of springs for supporting the body of a four-wheeled carriage. In one of these the body was suspended from the upper extremities of four C-shaped springs, the lower ends of the two front springs being secured to a platform or framework termed a perch, having a rigid connection with the fore-axle. In another the body rested directly upon four elliptical springs, two being in rigid connection with each axle. In the third arrangement the front of the body rested upon two elliptical springs similar in shape and adjustment to those used in the preceding class, whilst the back part rested upon two composite springs, which were for above half their length elliptical, and for the other half C-shaped. These composite springs rested upon and were fastened to the axle in the same manner as elliptical springs, their elliptical ends being placed below the body of the carriage. The sole object of employing springs is to prevent or mitigate jolting, and thereby promote the comfort of persons occupying the interior of the vehicle. The advantage which C-shaped springs, properly so-called, possess over elliptical, is that when the carriage is shaken, from any cause, they allow the body to sway horizontally as well as vertically, whereas elliptical springs only permit of vertical play. The witnesses appear to be agreed that composite springs such as I have described do permit of some degree of horizontal play in all directions, and are so calculated to produce easier motion than elliptical springs. One feature was common to the second and third of these arrangements. In both a 'full-lock' (which implies the capability of turning the fore wheels either to the right or to the left until they are nearly at right angles to the line of the body) can be obtained without using a perch, which is indispensable in the case of genuine C-spring carriages, and adds greatly to the weight of the machine. In 1876, some years after these composite springs came into use for supporting the back part of a carriage, Mr. Morgan took out a patent for the 'improvements in carriages' which the respondents claim as his invention. The leading claim in the specification is for 'the mode herein described of supporting the front of a carriage by C-springs, having their lower parts fixed to the axle, and their bows connected by links or loops to bearings fixed to the bottom bed of the under carriage substantially as and for the purposes herein shown and described.' On referring to the letter-press and drawings, it becomes apparent that the invention substantially consists in the substitution of composite for elliptical springs in the fore part of the carriage, so as to make the whole body rest upon four composite springs, instead of resting upon four elliptical, or upon two elliptical and two composite springs. For that purpose the patentee employs the same composite springs which were previously in use, and attaches them to the fore-axle in the same manner in which they were previously attached to the hind-axle, with this immaterial difference, that the C end of the spring is turned forward so that its elliptical end may be placed below the body of the carriage as in the case of the hindmost springs.

"The learned Judges of the Court of Appeal do not appear to me to have sufficiently considered the principle enunciated by Lord Westbury and accepted by this House, in Harwood *v.* Great Northern Railway Company (XI. House of Lord Cases, 682), to the effect that there cannot be a patent 'for a well-known mechanical contrivance merely when it is applied in a manner and to a purpose which is not quite the same but is analogous to the manner or the purpose in or to which it has hitherto been notoriously applied.'

"The springs described in the specification differ in no respect from carriage springs then in common use. The purpose to which they are applied is not only analogous to, but might fairly be described as identical with, the purpose which they previously served—viz., that of giving support to the body of a carriage. These circumstances are, in my opinion, fatal to the validity of the patent, unless it has been shown that inventive faculty has been displayed in the adaptation of composite springs to their new position in the front of the vehicle. But nothing of that sort has been shown. No mechanical contrivance or adjustment is specified or required in order to make the substituted springs fit into their new position or to render them efficient when they are placed there. On these grounds I am of opinion that the specification does not disclose a patentable invention."

The other learned Judges gave judgment to the same effect.

COTTON MILLS IN CHINA.

It is reported that the Chinese are about to make a vigorous effort for the erection of cotton mills, and for the production of cotton yarns and cloths by native labour. The Governor of Canton has presented a petition to the Emperor, advocating the establishment in Canton of cotton mills under Government supervision, and the purchase of machinery for reeling yarn and weaving cloth, with a view to the improvement of trade and the prevention of the outflow of money. He points out that since the commencement of trade with foreign nations a very large proportion of the import trade has been in foreign cloth and foreign yarn. He also states, what is now becoming very evident, that India and Ceylon are robbing China of her tea trade, and, further, that the silk trade is suffering very seriously, and he thinks that the only way to counteract these is to establish cotton mills in different parts of the country under Government supervision. Arrangements have already been made for one in the province of Kwang-Tung, to be carried on by a mercantile company with the assistance and, to a certain extent, under the direction of the Government, and machinery for it to the value of £87,000 has been purchased. The Governor of Canton points out that the various kinds of Chinese cotton are only suitable for the manufacture of three kinds of cloth, and that an admixture of foreign cotton is necessary for the manufacture of the seven kinds most in demand; that admixture is only about 30 per cent., and the low wages in China compared with the high rates abroad will enable much greater profits to be realised than in foreign countries. If the experiment should prove successful Government mills will also be erected at Shanghai and Hong-Kong, and later on at Tientsin and other parts of the empire. If this movement develops it will have a most important effect on our foreign trade, and we shall watch it carefully.

Letters to the Editor.

THOMSON ELECTRIC WELDING.

To the Editor of "Industries."

Sir,—Considerable prominence has been given, both in the United States and here, to a very favourable report which has been made by a Naval Board of the United States upon the potentialities of the Thomson electric welding process for naval purposes. It is a magnificent puff on the face of it, but its value tends to depreciate upon further examination. The subject of electric welding, to be investigated thoroughly, should have been submitted to a Board of electricians and engineers, but upon looking at the composition of the Board in question I find it to have consisted of Commander George A. Converse, A. S. Greene, Assistant Naval Constructor S. W. Armistead, and Ensign Gilbert Wilkes. The Commander, the Assistant Naval Constructor, and the Ensign, together with Mr. Greene, whose occupation is not defined, but who may be

"A bo'sun tight
Or a midshipmite,"

are possibly excellent persons in their own line, but what can they be expected to know of electricity or of welding? To entrust an inquiry of this kind to such a Board is a mere farce.

It seems from this that eccentricities in Government officials are not confined to Great Britain.

Yours, &c.,
N. D. O.

London, 31st March, 1890.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

Sir,—Your recent description of a low-pressure compressed air tramcar which has been tried at Chester is of interest, but to make the information of real value there should be some further details as to the cost of the system. I see that the car was only an experimental one, and the engineers are therefore hardly in a position to give quite accurate data as to expenses, but a rough estimate can no doubt be supplied. What forms an important factor in such a system where a new roadway is required is the expense of laying this. The figures, therefore, required before a judgment can be formed as to the value of the invention, are the cost per mile of laying the permanent way with its accessories, the cost of laying down the machinery for a line of given length, and the expense of running the same. If Messrs. Hughes & Lancaster could give a comparison between the expense of horse, electric, and steam traction as compared with their own system it would be of use to many interested parties.

Yours, &c.,
Car.

Portsmouth, 27th March, 1890.

To the Editor of "Industries."

Sir,—Almost coincident with your account of the new departure in compressed air tramcars there appears an American consular report from Consul-General Rathbone, of Paris, on a compressed air tramway motor which has been tried for two years on the Nogentais tramway near Paris. His description is very vague, as is usually the case when consuls refer to technical matters, but it contains a few scraps of information.

He states that air is compressed to forty or forty-five atmospheres; the reservoirs of the motor are charged at this pressure: the air to be used is reduced to a pressure of five to ten atmospheres, and at the same time heated to a high temperature and charged with moisture in a vessel called the heater (*rouillotte*); from there it passes to a double expansion engine, where it acts like steam in moving a piston rod. There is a saving of nearly 30 per cent. in favour of this system as against the Parisian omnibus service.

Various advantages are claimed, including several which are self-evident, but I give them as put down. They are, that the motor does not emit smoke or hot gases, and is almost noiseless; that a greater speed is attained than with horses when necessary; that a special track or overhead appliance is unnecessary; that, being very light, it can be easily handled on steep grades; that it is simple in form and does not frighten horses, and the machinery on the platform is almost invisible from outside; that a possible explosion of air reservoirs is less dangerous than of steam or superheated water; that maintenance in repair is very simple; that only one person is necessary for managing the machinery, and he is not necessarily a skilled engineer; and that in crowded days or times of day the number of passenger places may be easily augmented by the addition of one or even two tenders or ordinary cars, without a motor, thus making a short train.

Yours, &c.,
A. W.

London, 2nd April, 1890.

THE MELTING OF STEEL WITH WATER GAS.

To the Editor of "Industries."

Sir,—From the notices of the experiments made at the Leeds Forge in melting steel with water gas, which appeared in some technical journals last week, it may be inferred that the steel was made on the open-hearth of a Siemens furnace (with four regenerators), and that the fuel employed was a mixture of producer and water gas. A charge was made, it appears, in five hours with a consumption of fuel equivalent to 5 cwt. per ton of steel produced.

These figures are very interesting to steel makers, but it would be well if they could be supplemented by information on the following points, viz.:—Whether the water gas employed was mixed with gas from a Siemens producer, or with the gas, sometimes called "producer gas," which is made in the water gas apparatus; also whether the consumption given as 5 cwt. represents the fuel consumed in the production of water gas or of producer gas or of both combined.

No one will doubt that gas made in the Siemens producer may

Digitized by Google

be enriched by the addition of water gas (hydrogen and carbonic oxide free from nitrogen), and that by using such enriched gas in the Siemens furnace a higher temperature may be obtained than by using producer gas alone; but it may be questioned whether this can be done profitably both as regards cost of fuel and wear and tear of furnaces.

With regard to the melting of a charge in five hours at the Leeds Forge, in the Siemens crucible steel melting furnace, which was introduced about 1867, five to six charges have always been made per 24 hours in regular work; and if similar materials —viz., pig iron and puddled bar, or scrap, be used in an open-hearth furnace—steel should be melted as quickly in one case as in the other; and this indeed has been reported from the Continent. If the puddled bar is charged red hot, the working should be even more rapid, as in pot furnaces cold materials are exclusively employed. The notices concerning the use of water gas at the Leeds Forge refer to the fusion of pig iron and scrap, and it follows from what has been said that there is no evidence of improvement by the use of water gas, as, of course, the melting of steel in crucibles, and on the open-hearth, to which reference has been made, is effected with gas from the ordinary Siemens producers.

The statement that the normal production of puddled iron in an ordinary puddling furnace is as low as 14 cwt. per shift can only be looked upon as a clerical error, inasmuch as 32 cwt. per shift is the usual figure for a forge mixture, and the consumption of fuel 25 cwt. per ton of puddled bar, as may be found on reference to the standard works on iron and steel of Percy or Bauermann. A return which I have seen from the Pather Works, Glasgow, of the day and night shifts on the 24th of last month confirms these figures, the production of bar iron from an ordinary puddling furnace being given as 32 cwt. per shift, and the consumption of fuel 23 cwt. per ton of puddled bar. At the same works a double Siemens furnace of the new type has lately been set to work for puddling iron, and the production is returned as 3¼ tons of puddled bar per shift, which is fully equal to the ordinary furnace, whilst the consumption of fuel is reduced to 6 cwt. per ton of puddled bar. It would be interesting to learn the consumption of fuel in puddling with water gas.

Yours, &c.,
"GAS."

APPLIED MECHANICS. By James H. Cotterill, F.R.S., Professor of Applied Mechanics in the Royal Naval College, Greenwich. Second Edition. London: MACMILLAN & Co. 1890.

The first edition of Professor Cotterill's work on applied mechanics was published fully five years ago, and although the standard adopted by the writer has prevented it from becoming a popular treatise, it has been recognised by all teachers of the subject as, on the whole, the most complete and generally useful work of the kind we have in English. When, however, we speak of complete, it is, of course, understood that it is with the limitations commonly given to the term Applied Mechanics, for in its widest sense it includes all engineering science. In its restricted sense it is applied to the more theoretical parts of that science, and would be more correctly designated the "Dynamics of Construction and of Machines." Professor Cotterill belongs to the Cambridge school of mathematicians, which is very conservative of old terms, and "Mechanics" is often used by them when "Dynamics" would be employed by those whose education had been less formal. True conservatism, however, is generally found by going a little further back than people usually do, and in the case of the term we are discussing we are quite safe in adopting the signification given to it by Newton, who defined it as "the science of machines." Professor Cotterill's sub-title for his book is "An Elementary General Introduction to the Theory of Structures and Machines." We would suggest that when he brings out another edition that he call it simply a treatise on the "Dynamics of Construction and of Machines." Professor Cotterill in this, as well as in his treatise on the steam engine, takes up the work of Rankine, and carries it a step further, and at the same time simplifies it; and of course the name of Applied Mechanics is taken from Rankine. But it must be remembered that when Rankine wrote we had, practically, no treatises on the science of engineering in English, and Rankine, in many cases, adopted the nomenclature and methods of French writers. At the same time he widely extended the field of the science of engineering and placed it on a firm basis, and during the thirty years which have elapsed since Rankine's first treatise appeared immense developments have been made in every direction, and writers of the standing of Professor Cotterill should try to establish a systematic method of nomenclature.

The book itself gives an excellent introduction to the science both of structures and machines, and the selection of the subjects is one which will be most useful to all classes of engineering students. Towards the end some of the sections are unduly compressed, which the author himself admits, and says that, should the book continue to be found useful, he will, in a future edition, dwell at greater length on some of the more important sections.

We need not enter into details of the contents of the book, as they give in outline the course of instruction which the author has been in the habit of giving at the Royal Naval College, and cover the ground usually understood to be included under the name. The part on Structures is an excellent introduction to the subject, while that on Machines gives not only Rankine's method of treating the dynamics of the problems involved, but also Reuleaux's system of Kinematics, although in a much simpler form than in that writer's own works, which are too diffuse for the average British student. The section on Stiffness and Strength of Materials is, on the whole, the most generally useful treatment of the subject with which we are acquainted, while those on Hydraulics and Thermodynamics, although good in their way, are, as we have already said, too condensed to be in proportion to the other parts of the book. An Appendix gives notes and references which will be useful to those who wish to continue their studies in the higher departments. Throughout the treatise there is a large number of well-selected numerical and graphical examples, which are of great assistance to the students, for the author never gives an abstract rule without illustrating it by one or more well-chosen calculations or constructions. It is quite evident that Professor Cotterill is not only an authority on his own subjects, but is also one who has studied the difficulties of beginners, and taken them on in such a way as to enable them to overcome difficulties for themselves; in short, the book is the work of an educator, and not of a crammer.

THE SCIENCE OF METROLOGY, OR NATURAL WEIGHTS AND MEASURES. A Challenge to the Metric System. By Hon. E. Noel. London: STANFORD. 1889.

The Hon. E. Noel has endeavoured to show in this challenge and book of many names that "by very little alteration, and by a little amending, the existing English measures can be welded into a system *scientifically* as well as practically superior to the metric." We praise the author for his bold attempt, especially as he admits in the preface that he is neither a man of science nor a mathematician, and lays no claim to technical knowledge, but regret that we must unhesitatingly condemn any such patching up of our present system of weights and measures as he proposes. We admit there are advantages in a duodecimal notation which are missing when ten is the basis of notation, but no one proposes to make any such radical change as would give to these advantages any practical value, although the author seems inclined to prophesy a Utopia of this description in a future century. While making fun of the great metric system, he states that it has been adopted by every country of Europe and America, except the British Isles and their dependencies, Russia, the United States, and Turkey, and adds that if no worthy competitor appears in the field it may become the system of the whole civilised world. It is precisely this rapid development of the metric system that is its main argument for universal adoption, and we fail to see the advantages to be gained by first altering our present weights and measures as the author proposes, then inducing Russia to alter hers to suit the author's, and finally making a gigantic fight with the forlorn hope of ousting the metric system from the countries in which it is already firmly established. The novelty of the author's system appears to lie in the supposed advantages of a mixed duodecimal and decimal division of the standards in order to suit the requirements of persons who prefer "to halve and quarter," to dividing decimally. The author does not seem prepared to admit that ·5 conveys the idea of half-one as nearly as ½, and that children with an entire ignorance of decimal notation accept 5 as half-ten. We entirely agree with the author that a reform of the English measures is wanted, but hope that the time is gone for a natural preference for a national system to restrain our adoption of the measures which have already been found of such commercial utility by so many nations. We purposely abstain from urging the advantages to be derived from an adoption of the metric system on the grounds of applied science and from the fact that many derived units in daily use in all countries where electricity is employed would cease to have a meaning if a new universal system were adopted, as we believe that only those who, like Mr. Noel, are neither men of science, mathematicians, nor technologists, can possibly find points of agreement with his somewhat wild scehem.

THE WORKS MANAGER'S HAND-BOOK. Fourth Edition. By Walter S. Hutton. London: CROSBY LOCKWOOD & SON. 1890.

A book of this class, and of such size, which runs through three editions in a comparatively short time, has got beyond the stage of requiring a formal review; the constituency for which it was written has already settled its position in current engineering literature, by giving it a place among those works which ought to be found in the library or drawing office of all works managers who keep themselves up with the wants of the times. As, moreover, we noticed the last edition, we have another reason for not entering into a lengthened examination of its contents on the present occasion. For the benefit of those who have not seen our previous notice, we may say that the book is divided into six sections, the first of which is taken up with stationary and locomotive steam engines; the second, with hydraulics and its applications; the third, with millwork; the fourth, with steam boilers and their fittings; the fifth, with heating, warming, and ventilating; and the sixth, with the strength of materials and with workshop practice. In each of these room has been found for new matter by the excisions from the original work, and the whole has been brought up to date by a great many emendations and alterations. The first section has been for the most part re-written and improved by the addition of numerous illustrations and a variety of new matter relating to steam and gas engines. The second section, which treats of hydraulics, has been enlarged and illustrated, and much useful information regarding pumps and water supply has been added. Altogether, the alterations and improvements which have been made on it will add much to its utility as a book of reference, not only to those in charge of works, but also to all interested in mechanical engineering. Every engineer should of course, as far as possible, make their own hand-books from the results of their own experience, but there is no reason why they should not take advantage of the work of others, and those who utilise what is to be found in Mr. Hutton's book will have an excellent foundation from which to start.

THE PRACTICAL ENGINEER'S HAND-BOOK. Third Edition. By Walter S. Hutton. London: CROSBY LOCKWOOD & SON. 1890.

This volume is designed as a companion to the work by the same author which we have just noticed, and for the same reasons given above a very few sentences will be sufficient for our present purposes. It may, in a sense, be looked upon as the theoretical and experimental basis on which the other is laid, although it by no means excludes the practical, and the two together contain information on almost every point which is likely to come within the range of ordinary mechanical engineering practice. This edition does not differ in any material respects from the one which preceded it, although it has been carefully revised, and some new matter added to it by way of completeness. The information is conveyed in simple language, as far as possible freed from mathematical formulæ, and in a concise and condensed form, and it is illustrated by well-executed engravings which elucidate and shorten description. On the whole we think that the two books by Mr. Hutton which we have noticed will be found to contain more useful information, arranged in an orderly manner, on all the chief departments of mechanical engineering than any similar books in the English language, and we have no doubt they will be largely taken advantage of, both by practical men and by students of engineering. To the notice of the latter we would especially commend them, as they will serve to show them the shape in which their information requires to be put in order that it may be useful in everyday work. Both books are furnished with very complete indices, which make their contents easily available.

WELCH'S IMPROVED MIXER.

We illustrate herewith an improved apparatus made by Messrs. Francis B. Welch & Co., engineers, Manchester, for mixing thick and sticky substances. It will be seen that the vessel is mounted on three legs, and is provided with pulleys and mitre gearing for rotating the

internal stirrers. While in the mixer the substance is rendered more mobile by the heat from a coil which is arranged inside. Two outlets are fixed in the bottom of the mixer in order to facilitate the withdrawal of the contents.

BOARD OF TRADE RULES ON LIFE SAVING APPLIANCES.

The following is a synopsis of the Rules made by the Board of Trade under the "Merchant Shipping (Life Saving Appliances) Act, 1888," 51 and 52 Vict., c. 24. It was originally intended that these Rules should come into force on 31st March, 1890; but the date of their coming into operation has been postponed. In the effort to make the clauses quite clear, a rearrangement of their order has been found necessary:—

GENERAL EXPLANATIONS.

I. The Rules for *Steamers* of each class are kept distinct from the Rules for *Sailing Ships* of each class.

II. Each class is described in a self-contained section, and the expressions "as provided for above" and "as described above" have reference to the preceding matter in that section only.

III. The term "approved," whenever used descriptively, signifies that the article so described must conform to the requirements detailed under the General Rules.

GENERAL RULES.

I. Boats.

All boats shall be properly equipped as provided by these Rules.

Cubic Capacity of boats shall be ascertained as in measuring ships for tonnage capacity, by Stirling's rule, but in lieu of the application of that rule the following approximate measurement may be adopted for general purposes, and when no question requiring absolutely correct adjustment is raised:—

The length and breadth of boat outside and the depth inside (if the oars are pulled iff rowlocks the bottom of the rowlock is to be considered the gunwale of the boat for ascertaining her depth) multiplied together and by ·6 gives the capacity in cubic feet. Thus a boat 28ft. long, 8ft. 6in. broad, and 3ft. 6in. deep, will be regarded as having a capacity of 28 × 8·5 × 3·5 × ·6 = 499·8, or 500 cubic feet.

Construction and Buoyancy.—Properly constructed boats shall be of the following classes:—

Class A.—A life boat of wood or metal having for every 10 cubic feet of her capacity at least 1½ cubic feet of strong serviceable inclosed air and water tight compartments.

Class B.—A life boat of wood or metal having inside and outside buoyancy apparatus together equal in efficiency to the buoyancy apparatus provided for in boats of Class A. At least one half of the buoyancy apparatus must be attached to the outside of the boat.

Class C.—A life boat of wood or metal, having some buoyancy apparatus equal in efficiency to half the buoyancy apparatus provided for in boats of Class A or Class B; one half of the buoyancy apparatus to be attached to the outside of the boat.

Class D.—A properly constructed boat of wood or metal.

Class E.—A boat of approved form or material which may be collapsible.

Carrying Capability.—The number of persons a boat of Class A may carry shall be arrived at by dividing the capacity in cubic feet by 10, thus a boat of 500ft. of cubic capacity may carry 50 adult persons. The space in the boat shall be sufficient for the seating of the persons carried, and for the proper use of the oars.

The number of persons the boats of other classes (B, C, D, and E) may carry shall be according to the cubic capacity divided by 8.

Lowering and Disengaging Appliances.—Appliances for getting the boats into the water must fulfil the following conditions:—The boats placed under davits must be attached to the davit tackles and kept ready for service at any moment, and means to be provided for speedily detaching them from the lower blocks of the tackle. Hooks must not be attached to the lower tackle blocks. The davits to be of sufficient strength, and so spaced, that the boats can be swung out with facility; the points of attachment of the boats to the davits to be sufficiently away from the ends of the boats to ensure their being easily swung clear of the davits; the boats' chocks to be such as can be expeditiously removed; the davits, falls, blocks, eye-bolts, rings, and the whole of the tackling to be of sufficient strength; the boats' falls to be long enough to lower the boat into the water with safety when the vessel is light; the life-lines fitted to the davits to be long enough to reach the water when vessel is light.

Equipments for Collapsible or other Boats.—To be properly equipped, each boat shall be provided with the following:—

Full complement of oars (single-banked) and two spare oars.

Two plugs for each plug-hole, attached with lanyards or chains; and one set and a half of thole-pins or crutches, attached to the boat by sound lanyards.

A sea anchor, a baler, a rudder and tiller, or yoke and yoke lines, a painter of sufficient length, and a boat hook. The rudder and baler to be attached to the boat by sufficiently long lanyards and kept ready for use.

A vessel kept filled with fresh water.

Additional Equipments for Boats of Classes A and B.—To be properly equipped, each boat of these classes, in addition to the requisites specified above, shall be provided with the following (but not more than four boats in any one ship require to have this outfit):—

Two hatchets or tomahawks, one to be kept in each end of the boat and attached thereto by a lanyard.

A mast or masts, and at least one good sail, and proper gear for each.

A life-line, in loops run round the outside of the boat and securely made fast.

An efficient compass.

One gallon of vegetable or animal oil, in a vessel of an approved pattern, for distribution on the water during rough weather.

A lantern, trimmed, with oil in its receiver sufficient to burn eight hours.

II. Life Rafts.

Carrying Capability.—The number of persons any approved life raft for use at sea may carry shall be determined with reference to each separate type of life raft approved by the Board of Trade; provided always, that for every person so carried there shall be at least 3 cubic feet of strong and serviceable inclosed air-tight compartments, such that water cannot find its way into them. Any approved life raft of other construction may be used provided that it has equivalent buoyancy to that hereinbefore described. Every such approved life raft shall be marked in such a way as to plainly indicate the number of adult persons it can carry.

Equipment.—Life rafts shall be fully provided with a suitable equipment.

III. Buoyant Apparatus.

Approved buoyant apparatus shall be deemed sufficient for a number of persons, to be ascertained by dividing the number of pounds of iron which it is capable of supporting in fresh water by 32. Such buoyant apparatus must not require to be inflated before use, must be of approved construction, and marked in such a way as plainly to indicate the number of persons it is sufficient to support.

IV. Life Belts.

An approved life belt shall mean a belt which does not require to be inflated before use, and which is capable at least of floating in the water for twenty-four hours with 10lb. of iron suspended from it.

V. Life Buoys.

An approved life buoy shall mean either

A life buoy built of solid cork and fitted with life-lines and loops securely seized to the life buoy, and capable of floating in the water for at least twenty-four hours with 32lb. of iron suspended from it; or

A strong life buoy of any other approved pattern and material provided that it has buoyant properties equal to above, and provided also that it does not require inflation before use, is not stuffed with rushes, cork, or other shavings, loose granulated cork or other loose material.

VI. Position of Life Belts and Life Buoys.

All life belts and life buoys shall be so placed as to be readily accessible to the persons on board, and so that their position may be known to those for whom they are intended.

VII. Steamers.

Class 1.—*Rules for Steamers carrying Emigrant Passengers subject to all the provisions of the Passengers Act.*

Steamers of this class shall carry boats in number and capacity not less than are given in the following table, placed under davits and having proper appliances for getting them into the water, but no steamer of this class shall be required to carry more boats so placed than will furnish sufficient accommodation for all persons on board. The boats are to be equipped and of the description defined in the foregoing General Rules.

TABLE FOR STEAMSHIPS OF CLASS 1.

Gross Tonnage. 1.	Minimum Number of Boats to be placed under Davits. 2.	Total Minimum Cubic Contents of Boats to be placed under Davits. L. × B. × D × ·6. 3.
9,000 and upwards	14 ...	5,250
8,500 and under 9,000.....	14 ...	5,100
8,000 ,, 8,500.....	14 ...	5,000

750 ,, 1,000.....	4 ...	1,000
500 ,, 750.....	4 ...	800
250 ,, 500.....	2 ...	400
150 ,, 250.....	2 ...	300

Note.—Where in vessels already fitted the required *cubic contents* of boats placed under davits is provided, although by a smaller *number* of boats than the *minimum* required by this table, such boats shall be regarded as complying with these rules.

Masters or owners of steamers of this class claiming to carry a smaller number of boats than is indicated in the following table must declare before the collector, or other officer of Customs at the time of clearance, that the boats actually placed under davits are sufficient to accommodate all persons on board, allowing 10 cubic feet of boat capacity for each Statute adult.

Not less than half the number of boats placed under davits shall be life boats properly constructed of wood or metal, each having for every 10 cubic feet of its cubic capacity at least 1½ cubic feet of strong enclosed air-tight compartments, such that water cannot find its way into them, or they may be life boats properly constructed of wood or metal having inside and outside buoyancy apparatus together equal in efficiency to the buoyancy apparatus described above. (At least one-half of the buoyancy apparatus to be attached to the outside of the boat).

The remaining boats may also be of above description, or they may, in the option of the shipowner, have some buoyancy apparatus, equal in efficiency to one-half the buoyancy apparatus above described, such consisting of inside air-tight compartments as above described, or of apparatus attached to the inside and outside of the boat (at least one-half being to the outside). Two of said remaining boats may, however, simply be properly constructed boats of wood or metal.

If the boats placed under davits in accordance with the foregoing table do not furnish sufficient accommodation for all persons on board, then additional wood, metal, collapsible or other boats of a suitable description (whether placed under davits or otherwise) or "approved" life rafts, shall be carried. Such additional boats or rafts shall be of at least such carrying capacity, that they and the boats placed under davits provide together, in the aggregate, double the minimum cubic contents required by column 3 of Table. All such additional boats or rafts shall be placed as conveniently for being available as the ship's arrangements admit of, having regard to the avoidance of undue encumbrance of the deck, and to the safety of the ship for her voyage.

When steamers are divided into efficient water-tight compartments, so that, with any two of them in free communication with the sea, the vessel will remain afloat in moderate weather, they shall only be required to carry *additional boats* or life rafts of *one-half* the capacity required by preceding paragraph.

In addition to life boats and life rafts steamers of this class shall carry not less than one "approved" life buoy for every boat placed under davits. They shall also carry "approved" life belts or other similar "approved" articles of equal buoyancy suitable for being worn on the person, so that there may be at least one for each person on board the ship.

Class 2.—*Rules for Foreign-going Steamships carrying Passenger Certificates under the Merchant Shipping Acts.*

Steamships of this class shall be subject to the same requirements as those in Class 1.

Class 3.—*Rules for Foreign-going Steamships not Certified to Carry Passengers.*

Steamships of this class shall carry on each side, at least, such boats of wood or metal, placed under davits, that the boats on each side shall be sufficient to accommodate all persons

Digitized by Google

on board. One boat on each side shall be properly constructed of wood or metal, having for every 10 cubic feet of her capacity at least 1½ cubic feet of strong and serviceable enclosed air-tight and water-tight compartments; or it may be a life boat, properly constructed of wood or metal, having inside and outside buoyancy apparatus together equal in efficiency to the buoyancy apparatus provided for above, at least one-half of which shall be attached to the outside.

Steamships of this class shall carry "approved" life belts, as required for steamships of Class 1.

They shall also carry not less than six "approved" life buoys.

CLASS 4A.—*Rules for Steamships having Passenger Certificates, under the Merchants' Shipping Acts, authorising them to carry Passengers anywhere within the Home Trade Limits—that is to say, between Places in the United Kingdom or between the United Kingdom and Ports in Europe between the River Elbe and Brest.*

Steamships of this class shall carry boats placed under davits, in accordance with the rules and table provided for steamships in Class 1.

If the boats placed under davits in accordance with this requirement do not furnish sufficient accommodation for all persons on board, then additional approved boats or approved life rafts shall be supplied as for steamers of Class 1.

Provided that if (having regard to the avoidance of undue encumbrance of the deck and to the safety of the steamer for her voyage) it is not practicable for a steamer of this class to carry additional "approved" life boats or "approved" life rafts as are required for steamers of Class 1, the deficiency so caused may be made up by an equivalent supply of "approved" buoyant deck seats or other "approved" buoyant deck fittings to the satisfaction of the Board of Trade officer.

Steamships of this class shall carry not less than six "approved" life buoys.

They shall also carry, in addition to the boats and appliances required above, "approved" life belts, or other similar approved articles of equal buoyancy, suitable for being worn on the person, so that there may be at least one for each person on board.

CLASS 4B.—*Rules for Steamships in the same Trades not Certified to carry Passengers.*

Steamships of this class shall carry, on each side, at least so many and such boats of wood or metal placed under davits that the boats on each side of the ship shall be sufficient to accommodate all persons on board. The boats shall have proper appliances for getting them into the water, and one on each side shall be a life boat properly constructed of wood or metal, having for every 10 cubic feet of her capacity at least 1½ cubic feet of strong and serviceable enclosed air-tight compartments, such that water cannot find its way into them, or it may be a life boat properly constructed of wood or metal, having inside and outside buoyancy apparatus together equal in efficiency to the buoyancy apparatus provided for above, at least one-half of which shall be attached to the outside of the boat.

Steamships of this class shall carry "approved" life belts, as for steamships of Class 1. They shall also carry not less than four "approved" life buoys.

CLASS 5.—*Rules for Steamships having Passenger Certificates authorising them to carry Passengers within certain specified Limits of the Home Trade—that is to say, on short specified Passages along the coasts of the United Kingdom, or between Great Britain and Ireland, or between Great Britain or Ireland and the Isle of Man.*

Steamships of this class shall, according to their tonnage, carry boats placed under davits, as required by the foregoing Table, for ships in Class 1.

If the boats placed under davits, in accordance with the above requirements, do not furnish sufficient accommodation for all persons on board, then additional boats or "approved" life rafts shall be supplied as for ships of Class 1.

Provided that if (having regard to the avoidance of undue encumbrance of the deck, and to the safety of the ship for her voyage) it is not practicable for a steamship of this class to carry additional "approved" boats or "approved" life rafts as required for steamships of Class 1, the deficiency so caused may be made up by an equivalent supply of approved buoyant deck-seats or other approved buoyant deck-fittings to the satisfaction of the Board of Trade officer.

Steamships of this class shall also carry "approved" life belts or other similar approved articles of equal buoyancy, suitable for being worn on the person, so that there may be at least one for each person on board the ship.

They shall also be provided with at least one "approved" life buoy for each boat of wood or metal carried, but in no case shall less than six "approved" life buoys be provided.

CLASS 6.—*Rules for Steamships carrying Passengers on Short Excursions or Pleasure Trips to Sea, or in Estuaries or Mouths of Rivers during Daylight or across the Straits of Dover.*

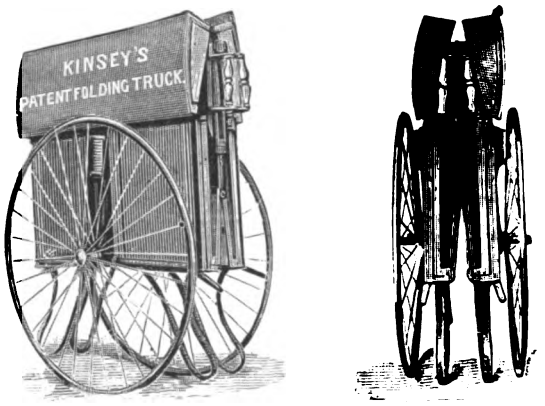
Steamships of this class shall carry at least two boats, placed under davits, and with proper appliances for getting them into the water. Such boats to be properly constructed life boats of wood or metal, having for every 10 cubic feet of their capacity at least 1½ cubic feet of strong and serviceable enclosed air-tight compartments, such that water cannot find its way into them; or they may be life boats properly constructed of wood or metal, having inside and outside buoyancy apparatus, together equal in efficiency to the buoyancy apparatus provided for above, at least one-half of which shall be attached to the outside.

Steamships of this class shall also carry other boats, "approved" buoyant apparatus, [and] [or] "approved" life belts sufficient (with the boats) to keep afloat all the persons on board the steamer.

They shall also carry at least four "approved" life buoys.

CLASS 7.—*Rules for Steamships carrying Passengers on Rivers and Lakes, or on Lakes only, but not going to sea or into rough waters.*

Steamships of this class shall carry one boat in such a position that it can readily be got into the water. They shall also carry "approved" buoyant apparatus or "approved" life belts, and "approved" life buoys at least sufficient (together with the boat) to keep afloat all persons on board (a discretion to be exercised by the Board of Trade officer to relieve ferry boats in narrow waters from the operation of this rule).



(To be continued.)

PATENT FOLDING TRUCKS.

IN our notice on the late Ironmongers' Exhibition at the Agricultural Hall, we referred briefly to the patent folding trucks exhibited by the Folding Truck and Carriage Co., Bellevue Street, Swansea. We now illustrate one of these in the form of a covered truck, Fig. 1 showing it in use, and Figs. 2 and 3 being a side and end view respectively when the same is folded up. The blocks are self-explanatory.

FIG. 1.—VIEW OF TRUCK IN USE.

FIGS. 2 AND 3.—VIEWS OF TRUCK FOLDED.

THE THWAITE "SIMPLEX" GAS GENERATOR.

THE illustrations on page 331 show a vertical section and a front elevation of the Thwaite "Simplex" Gas Generator. Its simplicity of construction, economy, and regularity of working, and the ease of effecting the difficult work of clinkering, are its salient characteristics. One of the features of this generator is the means by which the air for partial combustion is heated. On referring to the illustrations it will be observed that the side of the vessel just round its hottest part is provided with an annular space through which the air is blown in by means of a steam-jet air-injector. In its passage around this cavity the air is heated by contact with the side plates, and it also is heated by the cast-iron hollow fire-bar bearer plate. By means of a drop or curtain wall shown in the section the volatile hydrocarbons are compelled to flow through the hot and incandescent portion of the fuel, and are thus rendered more permanent. This "Simplex" generator has a wide field of application for heating purposes where economy of fuel, equable working, and regularity of heat and smokeless combustion are valued. In proportion to its size it is very powerful, and the cost of repairs is exceedingly light. By its means a high annealing temperature in a furnace is maintained at a cost of about 1d. per hour in fuel. The generator is the invention of Mr. B. H. Thwaite, of Liverpool, and is manufactured by the Gaseous and Liquid Fuel Supply Company, Limited, of 25, Market Street, Manchester.

PRACTICAL WORKING OF THE ELECTRICAL SUBWAYS IN NEW YORK.

(From our New York Correspondent.)

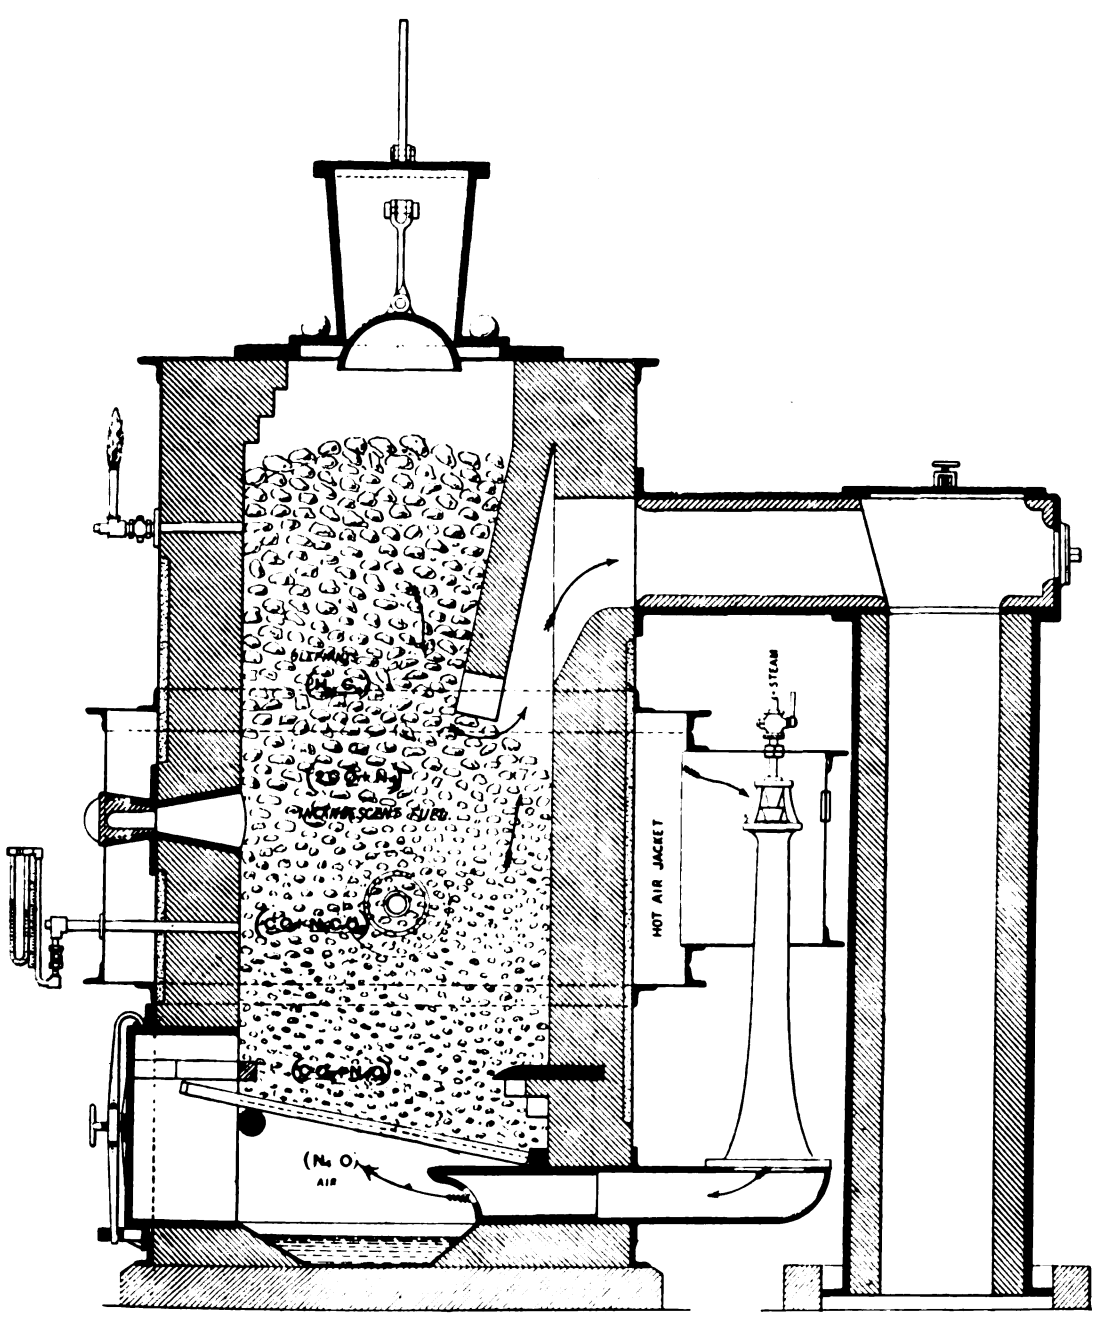
(Concluded from page 306.)

THE use of lead covering is not required by the subway rules. In addition to being a protection against the attack of acids and gases, it is considered a safeguard against accidents to men working in the man-holes amongst "live" wires. If a defect should occur in the insulation in the man-hole, the presence of a ground furnished by the lead covering would make the defect known at the regular test, which, if the defect were of a serious nature, would ensure its being located and eliminated. Whereas, if the conductor were not lead covered, there is a probability that a defect in the insulation might occur which would not be indicated by the test, but which might expose the conductor and render it impossible for workmen in the man-holes to make contact therewith. It would be quite possible for a workman to handle the lead covering of even a defective conductor without injury since the lead covering is grounded throughout the length of the subway. It is a fact that live electric light wires conveying the alternating and high tension arc currents are handled and moved about in the man-holes by means of the lead covering without the slightest indication that such wires are alive. It is quite a common occurrence to start up alternating circuits immediately after a rubber joint has been made in order to save time, and then to have the plumber adjust and wipe the sleeve on to the lead cover while the current is in full operation. No shocks whatever due to induced currents in the lead covering are felt by the workmen in handling the lead-covered cables conveying the alternating current. It is quite conceivable that such shocks might be noticed, where the cables are suspended from point to point and insulated. In that case, any one handling the lead covering of the conductors would doubtless receive the accumulated induced charge.

The requirements of the rules of the Subway Compans as regards insulation are such that none but a first-clas insulation can well be employed on the conductors conveying currents of high electromotive force. These rule require an initial insulation of 50 megohms per mile per 100 volts electromotive force employed on the circuit, and a minimum of 5 megohms per mile per 100 volts. The initial test is made when the conductor is first laid in the subway and prior to the turning on of the current. The minimum requirement is allowed after the circuit has been in use. This insulation requirement refers to the conductor proper in the subway, and does not include the lamps, aërial connections, or converters. The rule does not apply to conductors conveying currents of less than 100 volts e.m.f. In the case of alternating circuits, the uniform electromotive force employed in this city being 1,000 volts, the conductors to be employed in this service are required to show an initial insulation resistance of 150 megohms per mile, and a minimum insulation resistance afterwards of at least 50 megohms per mile.

The average e.m.f. of the arc light circuits in the subways is about 2,000 volts; but in some instances it runs up to 3,500 volts. In the latter case, the initial insulation resistance required by the rules is 525 megohms per mile; minimum, 175 megohms per mile. Experience in the New York subways has shown that it is vastly easier to maintain the insulation resistance at 150 and even 500 megohms per mile than it has been in the past in other cities to maintain them at one megohm per mile. The high tension electric light conductors are tested weekly for insulation resistance. The tests are made by the direct deflection method, a Thomson reflecting galvanometer being used, and as a rule 100 volt chloride of silver battery is employed as a testing battery.

The subway conductors are, as a rule, tested exclusive of arc lamps, converter, and inside wiring, but frequently also the tests are made inclusive of arc lamps and converters. The latter are only accepted when the results fairly indicate that the fall of insulation is due to the lamps or converters. Tests of circuits are not made inclusive of house wiring, because of the generally low results of trial tests. Some such tests showed an insulation resistance of the house wiring of less than 1,000 ohms.



Tests with converters included in some cases show very fair insulation. One circuit, with 34 converters included, showed 11 megohms insulation resistance. Another, with 11 converters included, gave a total insulation resistance of 159 megohms. It is not uncommon to get an insulation resistance of from two to five megohms with 30 and 40 converters in circuit. These tests did not include aërial portions of circuits. It should be said that the insulation of the converters and connections is being constantly improved.

About 130 miles of the subway electric light conduc-

THE "SIMPLEX" GAS GENERATOR.

DESIGNED AND CONSTRUCTED BY MR. B. H. THWAITE, ENGINEER, LIVERPOOL.

VERTICAL SECTION THROUGH GENERATOR

FRONT VIEW OF GENERATOR.

tors referred to are employed as carriers of alternate current for incandescent lighting, and about 60 miles as carriers of arc light circuits and incandescent continuous current. These circuits vary in length from 1 mile to 11 miles; the longest arc light circuit is 10 miles in length; the longest alternating circuit is 11 miles in length. In 10 miles of alternating or arc circuit there are from 450 to 500 joints. The greateat number of converters on one subway circuit is 65. There are 14 arc light circuits and 25 alternating circuits in the subways. Quite recently an alternating circuit for arc lamps has been installed in the subways, which is intended to be the pioneer of numerous such circuits.

The presence of gas is the most serious defect of electrical subways in cities. The ducts used in the subways are not only joined together as nearly hermetically as possible, but, except in the case of distributing ducts, they are laid in a solid body of cement from man-hole to man-hole. Whatever may be the mode by which point the gas enters the subways, its unwelcome presence is acknowledged, and while it is self-evident to anyone who will investigate the matter for himself, and is actually admitted by the gas companies, that the gas emanates from the gas mains in the streets, nevertheless the subway enginers have been constantly at work devising means to remove the intruder. Various methods of ventilating the subways have been suggested and tried, the most successful of which thus far has been the ventilation of the subways by the use of blowers stationed at intervals along the subways, and arrangements are now in progress to place fifteen such blowers in operation to cover the entire subway system. As the ducts become filled with cables, however, the free passage of air through them is prevented, and in this way the utility of the blowers is diminished. In order to evade this difficulty a 6in. wrought-iron pipe has been laid above the subway ducts in the more recently constructed subways. This large iron pipe has openings at each man-hole. It has been frequently suggested that good results might follow a suction method of ventilation, but experience has shown that this would rather aggravate the evil, as it would draw into the subway all the accumulated gas in the streets, besides inviting a larger leakage from the gas mains.

Experience has led to the following conclusions:—That it is possible to successfully operate all classes of underground electric conductors in cities. That, at least for conductors conveying high tension currents underground, it is advisable to set the standard of insulation high. That regular insulation tests of the conductors are very valuable. That liberal thickness of insulation is desirable for high tension currents. That it is unadvisable to place underground new types of cable or insulation until they have been subjected to tests and conditions analogous to those to which they will be subjected underground. That for electric lighting conductors—especially distributing mains—many conductors under one cover are not advisable, owing chiefly to the difficulty in making joints in such cables. That all sharp edges in ducts should be avoided. That until the gas light companies are required, like the electric light companies, to maintain their mains in a fairly sound condition underground, a means of ventilating the subways should be provided at the time the subways are contracted for. That while other features may be accessories thereto. the employment of smooth strong conduits, accessible ducts for distribution of the current, first-class insulation, constant expert attention to details, and thorough organisation in every department are essential to the production of a successful electrical underground system.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

AT the meeting of this Institution on the 27th ult. a paper was read, on "Alternating *v.* Continuous Currents in Relation to the Human Body," by Mr. H. Newman Lawrence and Dr. Arthur Harries, of which the following is a brief abstract:—

The experiments and observations upon which our contribution is based form part of a series of data connected with investigations upon which we are engaged with the hope of solving some of the physiological problems occurring in the course of our electro-therapeutic work at the Institute of Medical Electricity. The results obtained led us to note how strongly they bore on the question now before us. They differ from the experiments of D'Arsonval, Harold P. Browne, and others, in the important point that they deal, not with the bodies of rabbits,

Digitized by Google

dogs, and horses, or other animals (from which conclusions regarding human life have to be evolved), but directly with the human body. Our experiments have not been made with the powerful currents dealt with in electric lighting and distribution of power. We have used small currents, for the most part at low e.m.f., and have directed our attention to—1st, the determination of the resistance of the human body and skin to the passage of currents under certain conditions; and, 2nd, a comparison of the sensations produced in the human body by passage of the two forms of current. Our experiments have been made with the skin *normally dry* and *moist*, and we have selected measurements taken from hand to hand, as the hands are the parts most likely to come into contact with wires and other conductors. We find the—

Average Resistance				Ohms.
To the continuous current, moist with *salt* and water				= 9,557
,,	alternating	,,	,,	= 1,405
,,	continuous	,,	,, distilled water	=15,250
,,	alternating	,,	,, ,,	= 1,722
,,	continuous	,,	dry	=38,140
,,	alternating	,,	,,	= 4,155

When this difference between alternating and direct currents became apparent we thought it well to confirm our experiments by repeating them as far as possible under conditions such as would occur in actual working. The continuous-current tests were made with a Wheatstone bridge of Post Office pattern and a mirror galvanometer. The alternating-currents tests were made with one of Kohlrausch's rheometers, in which the balance is observed through a telephone. The *alternating* currents obtained from the induction coil of the instrument had a periodic frequency of about 300 per second. These results indicate that the resistance of the human body to continuous current is 6·8 times greater than it is to alternating currents when the skin is moistened, and 8·3 times greater when the skin is in its normal condition and not moistened by artificial means. The sensitiveness of persons to the *continuous* current varies very much, quite independently of variation of resistance. But we find that most people (and we have tested some hundreds) can bear without discomfort the passage of 10 milliamperes for a short time, and therefore for the purposes of this paper we will consider that amount of current-strength as the maximum which may be passed through the body without producing unpleasant sensations. With alternating *currents*, however, a very different state of things is disclosed; for having in the course of our therapeutic work found the great need for accurately measuring the alternating currents from induction coils, we obtained from Germany (after failing to find a suitable instrument of English make) a galvanometer recording milliamperes of alternating currents, and on putting it in circuit with a patient, were surprised to note that before the needle indicated the passage of a single milliampere the patient complained that the current was too strong, and practically unbearable. This, of course, led to further investigation, with the result that, though we tested a large number of persons of varied age and of both sexes, we found only a few who could bear with comfort the passage of one milliampere of alternating currents.

We can therefore confidently state that, as far as sensations are concerned, the human body can bear with ease at least five times as much of continuous-current strength as of alternating current strength. When this fact is taken in connection with the great difference in the resistance offered by the body to the two forms of current, it leads to the conclusion that the danger of unpleasant consequences, and possibly (if not probably) of loss of life, when currents of equal voltage are handled, is 34 times ($6{\cdot}8 \times 5$) greater with moist hands, and 41·5 times ($8{\cdot}3 \times 5$) greater with dry hands, when alternating currents are used than when the continuous current is employed. These figures we will adopt as representing the *danger-ratio*. As a practical example of this conclusion we may take the Board of Trade limit of pressure at which currents may enter houses, viz, 200 volts, and assume that a man having an average resistance handles naked wires within the house.

$$\text{With the continuous current (dry hands)} \left.\right\} C = \frac{200}{14{,}475} = 13{\cdot}5 \text{ milliamperes.}$$

He thus receives *only* 13·5 milliamperes, which is little more than, as shown above, he can take with perfect impunity.

$$\text{With alternating currents (dry hands)} \left.\right\} C = \frac{200}{1{,}740} = 115 \text{ milliamperes.}$$

He thus receives 57 times more current than he can bear without discomfort, and the danger of physiological shock is correspondingly increased.

In the discussion which followed, Professor Forbes said that the tests made and the results obtained had little bearing on the practical question of safety in the use of electricity for lighting and power purposes, for the conclusions arrived at in the paper were not in accord with actual experience. The sensations, he said, depend not on the mean current, but the maximum value of the current or volts; and in the case of an induction coil the volts on break were immensely greater (20 to 50 times) than the maximum occurring in a well-designed alternator which would send the same mean current through the body as that indicated by the measuring instrument used.

Mr. Kapp found he could bear 100 volts continuous with about the same discomfort as 40 volts alternating.

Major Cardew said shocks received from old Wilde machines were very severe, even when the volts were small; whilst from a modern alternator 100 volts may be taken without great discomfort. Referring to the Board of Trade regulations, he informed the authors that permission to use 200 volts alternating on consumers' circuits had never been granted.

Mr. Sayers thought sensation depends greatly on the shape of the e.m.f. curve and on the frequency of alternation.

Mr. Crompton said he had recently tested the resistances of individuals by Evershed's ohmmeter, 100 volts being used in all cases. As a rule he found the resistance to fall from 30,000 or 40,000 to 25,000 by continued application, and in some cases 10,000 or 11,000 ohms were indicated.

Mr. Joyce said that, even if the difference in the e.m.f. curves of induction coils and alternators in producing sensations were admitted, yet from the results in the paper one could see that there is a great difference between the resistances of the body to alternating and continuous currents. This of itself meant a serious difference in the "danger ratio."

Mr. W. H. Preece believed there had been more nonsense talked about this subject, particularly on the other side of the Atlantic, than on any other with which he was acquainted. Speaking of the so-called "dangers of electricity," he said the difficulty was to kill rather than to prevent being killed, and that the question was not one of high or low potentials, or alternating *v.* continuous currents, but of overhead *v.* underground mains, and bad or good workmanship and insulation.

Dr. Harries said he had anticipated more discussion on the physiological points raised. He remarked that the high voltage on breaks means little if the resistance be high. As regards the effect of frequency, he stated that the greater the frequency the less unpleasant a given current becomes.

Replying to the electrical points, Mr. Lawrence said the frequency of the alternating currents was about the same in all the experiments, and that from greater frequencies he would expect less effect.

Mr. Alex. Siemens (who was in the chair) said he had experienced the pain-alleviating properties of the electric current in the case of teeth extraction.

Notes.

A FRESH FIND OF SALT IN CHESHIRE.

THE *Chester Chronicle* reports that the sinking and tunnelling of the last nine months on Mr. Podmore's farm at Middlewich, Cheshire, has resulted in finding a plentiful supply of brine containing 2lb. 10oz. of salt per gallon. The work has been under the direction of Mr. Murgatroyd, of Stockport, and, before finding the brine, evidence had been obtained of two beds of salt of considerable thickness—the second deposit containing amber rock-salt of very fine quality. The property is, undoubtedly, of great value, and it is proposed to set up works immediately for evaporating the brine, and also to sink a shaft for mining the second bed of rock-salt.

ASSOCIATION OF SANITARY INSPECTORS.

THE position of sanitary inspector is beginning to be recognised as of some importance, and as almost all the County Councils are taking steps to have the sanitary affairs of their districts placed under proper supervision, it is likely that soon a distinct profession may be organised. In fact, that to a certain extent has been done, for we have already the Association of Public Sanitary Inspectors of Great Britain. The Council of this Association is naturally anxious to improve the positions of its members, and it is of opinion that the conditions under which sanitary inspectors are appointed and discharge their duties are inimical to the interests of the public health, and that those conditions are due to the defective state of sanitary law. The Council has recommended that the influence of the Association should be directed to secure the following amendments in sanitary law: That every candidate for the position of sanitary inspector shall have a general knowledge of the building trades, and in addition shall possess a certificate in sanitary science; that sanitary inspectors shall be elected to a permanent tenure of office, and shall only be dismissible for misconduct or proved incompetence, with right of appeal to the Local Government Board, with various other stipulations regarding salary and duties. In consequence of the probable demand for sanitary inspectors we understand that numerous classes in sanitation are being started in different parts of the country.

THE WOOD SUPPLY OF GREAT BRITAIN.

FROM a paper recently read by Dr. W. Schlich we learn that about twelve million pounds sterling are paid every year for timber by the British Empire, and the author pointed out that the United Kingdom had waste land amounting to over 26,000,000 acres, one-fourth of which would be sufficient to produce all the ordinary timber now imported into the country. Part of this was, of course, wanted for other purposes, but still, if systematic forest management were introduced, a great deal of timber might be produced. The author urged that, in spite of the constitutional aversion of Englishmen to State interference in anything like an industry, it was most essential that energetic steps should be taken to prevent the serious consequences that would arise from a failure of the wood supply of the Empire. Nominal interference only would be disastrous. The forests must be treated in a systematic manner, and the State should either set aside certain areas for forest purposes or by legislation take upon itself the management of communal and even private woodland. He pointed out the great improvement which had recently taken place in India since the Forests Departments had been reorganised, and a competent staff of officers provided, to be reinforced by those educated at Cooper's Hill College. Dr. Schlich also placed before his hearers an exhaustive account of the action of the Australian colonies with regard to the regulation of wooded lands by the State, contending that in no case had sufficient steps been taken to ensure a lasting and continuous supply of timber.

SCOTCH RAILWAY RETURNS.

THE proposed changes in the management of the Scotch railways cause unusual interest to be attached to the returns which have been recently issued, are receiving a considerable amount of attention. During the half-year there has been an increase in the traffic of each railway by the following amounts:—

North British	£59,930
Caledonian	48,574
South-Western	8,338
	£116,842

On the other hand, there has been an increase in the working expenses by the following amounts:—

Caledonian	£51,454
North British	36,512
South-Western	15,358
	£103,324

which show a most remarkable difference in the dividend values of the various increases, and further that for some reasons, or others, the North British has been able to do its half-year's work very much cheaper than either the Caledonian or the South-Western. Various special items have no doubt entered into the accounts of the two latter during the past half-year, but they are not in themselves sufficient to account for the difference, the reasons for which will no doubt receive the careful attention of some of the shareholders.

THE PRESENT CONDITION OF PANAMA.

THE effects of the collapse of the Panama Canal scheme on Panama and Colon are described in a recent interesting report from the American Consul at the latter port. The decadence of Colon, he says, and the almost entire prostration of all business since the collapse of the canal become more and more apparent. It very often happens that not a single vessel is to be found in the harbour, where but a short time since vessels were obliged to anchor out for days waiting for dock room at which to unload their cargoes. The local traffic of the isthmus while the work on the canal was proceeding had reached vast proportions. The route for about fifty miles was a vast bivouac, where the most energetic of all nationalities and races had congregated to amass wealth, and many, especially the Chinese, have done so. Wages were high, princely salaries were paid, money was easily made and freely expended. Daytime was not enough; the nights themselves were turned into day, and, literally speaking, the twenty-four hours of the day were a constant draft on various industries. Forty towns sprang up on the line in almost as many miles, every one of them a real beehive of people of all races and tongues. Now the people have all gone and business is dead. Colon and Panama still live, but that is all—merely bye-way stations for the traffic across the isthmus eastward and westward between two hemispheres. In Colon rents have fallen off 500 per cent. in three months, and are still on a decline. The Panama railroad, which in 1888 paid 23·50 per cent. dividend, will in 1889 pay only 9 per cent. This line in 1888 carried 1,300,000 passengers (4,000 every day); this year it will carry probably 500,000, if so many. But the transit traffic has not suffered; local traffic only has been affected, but this to such an extent that nearly two-thirds of the business houses in Colon are closed, and bankrupt sales are of daily occurrence.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents)."

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

17th March, 1890.

4104. Roberts, A., Jun. ..... Lathes.
4107. Bradshaw, A..... Lubricators.
4110. Hartley, G..... Mules.
4117. Rhodes, Rhodes, & Rhodes..... Grooved pulleys.
4119. De Baere, P. ..... Rock boring apparatus.
4122. Jackson, E..... Band sawing machinery.
4126. Berg, E. ..... Indicator.
4127. Dewar, A. ..... Projectiles.
4128. Walker & Stephenson (trading as John Perry)..... Washing machines for fibres.
4131. McEwen, J..... Water gauges.
4133. Roberts & Belden ..... Grinding and amalgamating pans.
4139. Glüser, H. ..... Water gauge.
4144. Morrell, J..... Brakes for vehicles.
4147. Müller, E. ..... Wood working machinery.
4148. Pol & Künzel ..... Car brakes.
4152. Picking & Hopkins ..... Drying machines.
4153. Simonet, M. H. ..... Crushing machine.
4154. Shepherd, G. H. ..... Lawn mowers.
4157. Wallwork, R. ..... Machinery for finishing hats.
4158. Brigham, M. E. ..... Paper box making machinery.
4162. Newton, H. E. ..... Boilers and furnaces (*Cartwright*).
4164. Abel, C. D. ..... Governing gas engines (*Gas Motoren Fabrik Deutz*).
4166. Cornero, C..... Propelling and steering ships.
4167. Marshall, J. ..... Thrashing machines.
4168. Spanoghe, J.-E..... Screw propellers.
4169. Edwards, E. ..... Stuffing boxes (*Gminder*).
4176. Parkinson & Parkinson Sieves for grading grain.

18th March, 1890.

4184. Howe, C. J..... Disengaging boats.
4194. Hahn, J. ..... Railway brakes, signal, and switch operating mechanism.
4195. Hawksley, G. W..... Furnace bars.
4196. Barlow & Barlow ..... Jacquard harness.
4201. Teague, T. ..... Smelting furnaces.
4203. Vicars, Vicars, & Vicars Mechanical stokers.
4209. Smith & Sutton..... Apparatus for cutting cloth.
4214. Ballach, A..... Sowing machines.
4217. Van Vestraut, L..... Apparatus for charging inclined gas retorts.
4229. Melendy, B. H. ..... Dough-kneading machines.
4230. Powell & Bennett ..... Expanding pulleys.
4234. Sorel, E. E. A. ..... Manufacture of wheels.
4236. Smith, W. E. ..... Apparatus for burning liquid fuel (*Bray*).
4239. Apostoloff, L. ..... Submarine vessels. (10th September, 1889).
4240. Seymour, C. J. ..... Elevators and conveyors.
4242. Searles, J. E..... Disintegrating machines.
4244. Galloway & Beckwith Expansion valves.
4245. Rowe, G. E..... Mowing and reaping machines.
4247. Scott & Tagg..... Ships' boats.
4249. Kesterton, H. ..... Explosion engines.
4250. Marshall & Wigram ... Engine valves.
4257. Thompson, W. P. ..... Brush-making machines (*Young & Robinson*).
4262. Thomson, J..... Water meters.

19th March, 1890.

4268. Ingram, G. ..... Locomotive engines.
4274. Crawshaw, R..... Looms.
4276. Preston, N. A. ..... Bearing for railway axles.
4281. Smith, Smith, & Smith... Apparatus for washing wool.
4282. Whyatt, H. J..... Machines for veluring hats.
4284. Johnson, W. ..... Fan for smiths' forges.
4288. Firth, A. ..... Lifting machinery.
4296. Burrell, F. J. ..... Compound locomotive engines.
4297. Burrell, F. J. ..... Undertype compound steam engines.
4299. Lees & Lees ..... Machines for mortising timber.
4302. Sproule, R. F. ..... Printing machines.
4307. Gill & Bradley..... Paper-cutting machines.
4309. Foster, J..... Evaporating and distilling apparatus.
4320. Jones, C. J..... Boilers.
4323. Hanneborg, O. B. H. ... Machines for making drains.
4325. Edwards, J. D. ..... Permanent way.
4326. Sahlström & Hill ..... Burner for liquid fuel.
4327. Tonnar, F. ..... Apparatus for manufacturing plush fabrics.

20th March, 1890.

4328. Scott & Thornton ..... Reducing valve.
4331. Gillibrand, R. T..... Boiler furnaces.
4333. Lindsay & Allan ..... Whip rails of looms.
4334. Lindsay & Lindsay ..... Let-off mechanism of looms.
4335. Baines & Baines ..... High-pressure valve cocks.
4336. Forknall, T..... Machinery for perforating paper.
4337. Bolton, R. ..... Cranes.
4338. Waters & Woodman ... Brush-making machinery.
4356. Wilkinson, A. J. ..... Pottery ovens.
4360. Robertson, J..... Machinery for glazing paper.
4361. Armitage, R. ..... Apparatus for winding yarn.
4362. Binns, J. P..... Gas engines.
4363. Sewell, S. J. ..... Brakes.
4367. Burrows, G. W..... Apparatus for washing bottles.
4368. Pullan, Mann, & Gill... Brick-making machinery.
4374. Engeldow & The Engineering Joint Stock Company ..... Heating apparatus.
4375. Morris, A. ..... Typewriters.
4379. Heslop, W. ..... Metal boats.
4380. Miles & Arter ..... Potato-planting machines.
4381. Arter, A. C. ..... Reaping and mowing machines.
4386. Von Ehrenwerth, J. ... Producing iron.
4387. McNaught & McNaught Barring engines.
4389. Lawrence, H..... Slide valves.
4392. English, T..... Mounting heavy guns.
4393. Lacoste, J. ..... Liquid meter.
4398. Boult, A. J..... Tidal motors (*Rankin*).
4401. Kenyon, Barnes, & Kenyon ..... Vices.
4402. Boult, A. J. ..... Pulverisers (*Meyer*).

21st March, 1890.

4410. Harrison, J. ..... Elliptical springs.
4411. Dienst, L. ..... Looms.
4416. Haddow, J. ..... Friction calenders.
4421. Field, E. ..... Steam engines.
4422. Stern & Brune..... Strengthening soft metal pipes.
4431. Howson & Milnes..... Boiler furnaces.
4432. Field, E. ..... Steam engines.
4433. Bell, W. ..... Valve gear.
4438. Hart & Baynes ..... Machines for cleaning cotton.
4442. Anderton & Barlow ... Locking screw bolts.
4443. Reid, W. ..... Reducing valves.
4454. Felstead & Smith..... Brake.
4455. Bauermeister, A. ..... Presses for preparing cement.
4457. Edwards, E. ..... Coke ovens (*Stroehmer*).
4459. Cussons, H. R. ..... Pumping apparatus.
4461. Hornsby & Smith ..... Sheat-binding apparatus.
4464. Peckham, E. ..... Bogie tramway trucks.
4465. Kirk, J. H. ..... Looms.
4466. Lake, H. H..... Regulating the pressure of fluids (*Jay et Jalliffier*).
4467. Carey, W. ..... Pipe couplings.
4471. Lake, H. H..... Training guns (*Maxim*).
4472. Tuerk, F. W. ..... Rotary fans.
4474. Gibson & Lilley ..... Pulley blocks.
4475. Lay & Owen ..... Machinery for manufacture of ropes.

22nd March, 1890.

4478. Wear, S. ..... Sieving apparatus.
4479. Presland & Pallant ... Compensating crank.
4483. Fowler, A. B..... Heel finishing machines.
4486. Muir, A. ..... Planing machines.
4487. Snelgrove, W. ..... Drain-clearing apparatus.
4488. Orr, M. L. ..... Machinery for washing bottles.
4493. Weir & Denholm ..... Harrow.
4495. Hetherington, J. M. ... Spinning machinery.
4497. Bradley, I. ..... Hot water apparatus.
4498. Marlow, C..... Machine for polishing glass.
4500. Brownlow, R. S. ..... Apparatus for removing solid matters from water.
4503. Thomas, F. ..... Lowering ships' boats.
4504. Lee, E. P. ..... Kilns for burning bricks.
4509. Rylands & Stoner ..... Machinery for manufacture of glass bottles.
4514. Preston & Co., Ld. ..... Compressed air tramcars (*Fitzgerald*).
4516. Aston, Aston, & Aston Presses for stamping metals.
4517. Barfoot & Langham ... Knitting machines.
4518. Thompson, W. P. ..... Apparatus for heading bolts (*Seaton & Seaton*).
4521. Leonard, H. S. ..... Machine for husking seeds (*Canterbury (N.Z.) Seed Company*).
4522. Morris, R. ..... Magazines for rifles.
4523. Abel, C. D. ..... Gas engines (*Gas Motoren Fabrik Deutz*).
4528. Schoone, C. I..... Stone cutting machine. (22nd August, 1889.)
4531. Downing, G. C. ..... Lubricator for air-compressers (*Lalance & Elsner*).
4532. Lawrance, E. G. ..... Evaporating liquors (*Pick*).

ELECTRICITY.

17th March, 1890.

4103. Campbell, J. ..... Arc lamps.
4116. Young, F. J. ..... Magneto call bells.
4125. Berg, E. ..... Electric bell.

18th March, 1890.

4189. Suter, F. ..... Electric switch.
4191. Farrall, T. D. ..... Generating heat, steam, and light by electricity.
4220. Holden, H. C. L. ..... Electric switches.
4231. Gray, W. E..... Arc lamps.
4232. Gray, W. E ..... Incandescent lamps.
4235. Rees, J. P. ..... Filaments for electric lamps.
4242. Siemens, A. ..... Electric railway signals.
4246. Forbes, Sir C. S. ..... Primary batteries.
4260. Thompson, W. P. ..... Electrical distribution (*Young*).

19th March, 1890.

4275. Kingdon, J. A. ..... Electrical switches.

20th March, 1890.

4350. Barnett, H. T. ..... Electric switch.
4366. Parker, T. H. ..... Electrical thermometers.
4383-4. Pitkin & Holden ..... Secondary batteries.
4405. Sayers, W. B..... Dynamos and motors.

21st March, 1890.

4407. McGrew, J. B. ..... Electric railways.

22nd March, 1890.

4533. Lake, H. H..... Safety devices for electric circuits (*The Thomson-Houston International Electric Co.*).

CHEMISTRY.

17th March, 1890.

4120. Laing, J. ..... Distillation of mineral oils.
4137. Piekenbrock, F. (of the Firm of Graf & Co.)... Producing "ozone oil."
4151. Candy, F. C. ..... Purification of sewage, &c.
4171. Negrier, C. S. ..... Concentrating sulphuric acid.
4181. Spitzer, S. ..... Manufacture of starch.

18th March, 1890.

4197. Müller & Adkins..... Lighting gas.
4223. Von Langer & Cooper... Water gas.
4224. Von Langer & Cooper... Enrichment of water gas.
4243. Schückher, W. ..... Explosive.

19th March, 1890.

4324. Kelman, J. A..... Manufacture of gas.

20th March, 1890.

4355. Hancock & Craig ..... Gas from mineral oils.
4382. Willcox, B. ..... Derivatives of phenyl-amido-acetic acid (*Farbenfabriken vormals Friedrich Bayer & Co.*).
4394. Ricard, F. ..... The ammonia soda process.

21st March, 1890.

4409. Muller & Webber ..... Aniline black.
4420. Beilly & Henderson ... Extraction of metals.
4434-5. Meldrum & Meldrum Distillation of ammonia.
4450. Turnbull, Stockdale, & Duerr ..... Mordanting cotton.
4473. Lake, H. H..... Carbonic acid (*Jay et Jalliffier*).

22nd March, 1890.

4519. Precht, H. ..... Potash.

MISCELLANEOUS.

17th March, 1890.

4111. Scotter, R. ..... Ships' berths.
4113. Bennett & Hides ..... Water pits and fountains.
4180. Oliver, G. H. ..... Separating dust from air.

18th March, 1890.

4185. Barr & Stroud ..... Range finders.
4208. Thomason, J. ..... Gas valve.
4218. May, A. ..... Removing paint.
4225. Von Langer & Cooper... Valves for hot gases.
4238. Etrich, I..... Spindles.
4259. Thompson, W. P. ..... Ring throstles (*Koldt*).

19th March, 1890.

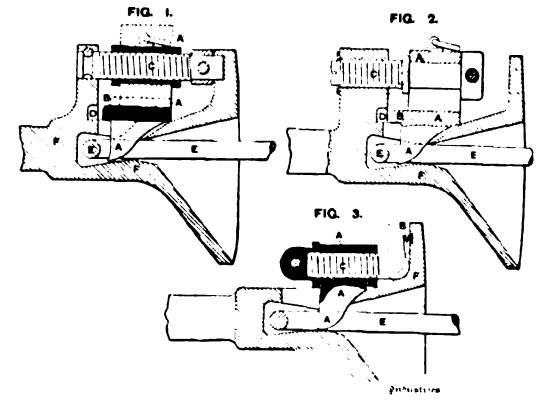
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

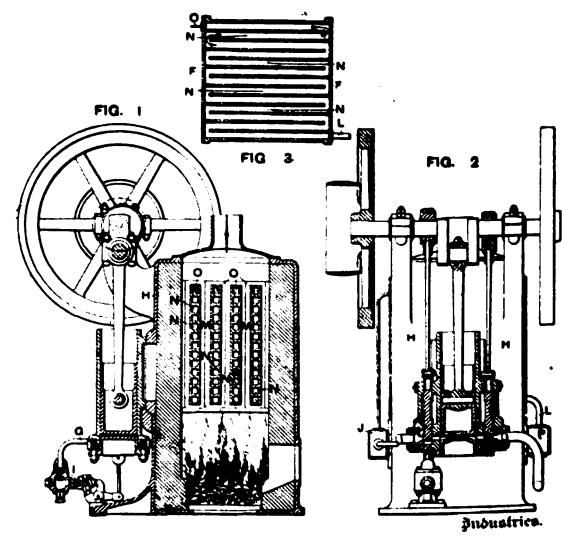
ENGINEERING.

Steam Boilers.—*W. J. Jobling, Newcastle-upon-Tyne.*—Special reference is made to marine boilers. The improvements are to adapt boilers to the use of high-pressure steam, yet obviate the necessity of using plates of exceptional thickness. The boiler is formed of a number of cylindrical vessels, disposed horizontally, and connected together by water tubes. In constructing a boiler of five vessels, three will be disposed side by side, with spaces between them to form the furnace. The vessels rest in cradles built upon the ship's "floors," and the furnace bottoms are carried over the "floors." The other two vessels are fixed above the three first, and joined to them by water tubes. The top vessels have tubes passing through them from end to end, but the lower vessels have one or more flues. The flames and gases pass along the outside of the vessels to the back end; there they divide, and return to the front through the flues of the lower vessels. It next passes upwards to the tubes of the top vessels, and through them to the back again and away to the chimney. Claim: The construction of steam boilers comprising a series of cylindrical shells, of comparatively small diameter, traversed longitudinally by fire flues or tubes, or by a combination of flues and tubes, the said shells being so disposed that furnaces, combustion chambers, and flues, or any of them, may be constructed externally to them, with the objects of securing strength to contain very high pressures, facilitating construction, and obtaining evaporative efficiency.—No. 6535. April 16th, 1889. 8*d*.



Looms.—*W. H. Crompton & W. Horrocks, Radcliffe, Lancashire.*—The object of this invention is to improve the mechanism which governs the shuttle changes in looms—firstly, by making its motion positive, yet so sensitive that immediately the weft thread breaks it is thrown out of gear and prevents the necessity of setting back the pattern chain; and, secondly, by using fewer cards or links for a pattern when a repeat frequently occurs. Fig. 1 is an elevation of part of a "Whitesmith's" loom with the above improvements introduced. Fig. 2 is a detail. In making the first improvement the lever A, which actuates the pattern barrel B, is worked by a bowl I travelling round the edge of the cam D; the bowl I being fixed to the lever A. The cam D is either mounted upon the tappet shaft C or fixed fast to the crank pin E. The crank pin E carries the long catch levers J employed in these looms for pulling round the wheels F which work the drop boxes. The bowl I is held against the cam during part of its revolution by a spring G, but during the effective part of its revolution the cam passes between guides N to give the lever A a positive motion. As soon, however, as the weft thread breaks, an arm or lever H, pivoted at K, is raised, and causes the catch L to engage with the catch M, and prevent the bowl I entering

the guides N of the cam, and consequently prevents the pattern barrel being worked. The second improvement is made by the addition of an extra pattern barrel and chain to those ordinarily employed. In this class of loom a small cam wheel O (Figs. 1 and 2) reverses the motion of the pattern barrel B by alternately disengaging the driving catches P, Q. The cam wheel O is driven by a ratchet wheel R and pawl S, the latter being supported upon an arm T worked by the pattern chain U. According to this invention the motion of this cam wheel O is governed by an extra pattern barrel V and chain W, which are actuated by a catch X upon the lever T. The chain N has enlarged parts or "risers" Y, which come under a "lifter" Z as the barrel V is revolved and lifts the pawl S out of the ratchet wheel R. The reversing catch is thus thrown out of gear, and the pattern chain U will proceed to a different part. Claims: (1) The combination with the pattern barrel lever and frame of a "Whitesmith's" or similar loom of a bowl, spring, and cam, partly single and partly double, revolving with the crank or eccentric (on the tappet shaft) which actuates the long catch levers; (2) the combination with the pattern barrel lever and frame of the spring, bowl, and cam, partly single and partly double, together with the means for automatically preventing the action of the said cam on the pattern barrel lever when the loom is stopped; (3) the combination with the main pattern barrel and chain which actuates the changes of shuttles, and the cam or wheel for reversing the motion of the said barrel and chain, of an extra barrel and chain for automatically preventing the action of the said cam or wheel when the "repeat" is no longer required.—No. 6040. April 9th, 1889. 8*d*.

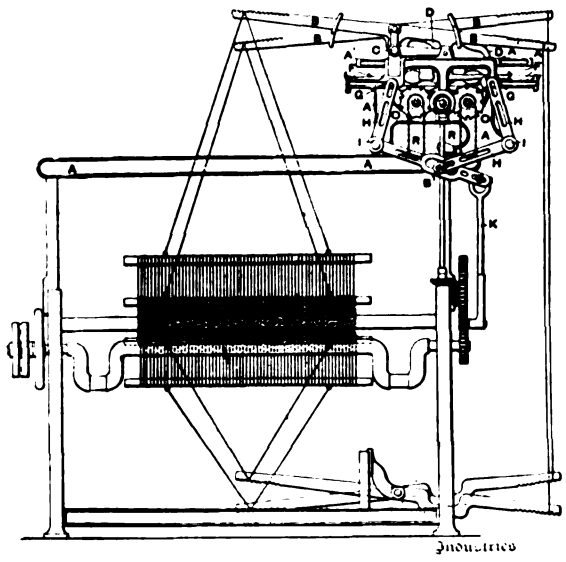


Grinding Card Flats.—*J. Jones, Dukinfield.*—This describes an apparatus to be applied to carding engines for the purpose of grinding the surface of the card teeth of endless or travelling flats. It consists of a fixing which is secured to the horn-bracket and is slotted to receive a bracket capable of sliding in a vertical direction. This sliding bracket carries at its upper part the journal of the emery grinding roller. It also carries an adjustable surface piece for compensating for the bevel of the working surface of the iron flat. This surface piece is adjustable in a slot of the sliding bracket, so that the distance between it and the centre of the grinding roller can be regulated. The surface piece rests upon the working surface of the iron flat, and causes the centre of the grinding roller to maintain a constant distance from the surface of the wire. Claim: The improved apparatus as described for grinding the flats of carding engines, especially the particular construction and use of the surface piece or guiding plate adjustable on the roller bracket for obtaining the necessary bevelling motion from the working surface of the flat, whether in combination with a fixed lifting bracket or with a weighted lever.—No. 6621. April 18th, 1889. 6*d*.

Railway Couplings.—*A. E. Schurr, Romford, Essex.*—Three forms of this coupling are shown in the accompanying illustrations. The coupling consists of a bell mouth block F slotted at the top to admit a catch A which acts as a detent to a link E when it is thrust into the bell-mouthed block; the link E is attached to the end of the opposite vehicle. The catch A is supported by

a screw C which is hinged in Fig. 3 to permit the catch A to rise and fall, but in Figs. 1 and 2 the screw is fixed, the catch being slotted to give it the necessary freedom upwards and downwards. By turning the screw C the catch A may be shifted to the back of the block F and so lock the link E in the coupling; the link being locked in the first two figures by the shoulder B entering the recess D, and in the third case by reason of the position in which C is hinged. In a modified form the catch A is constructed to be forced backwards for the purpose of locking the link by a lever instead of a screw as illustrated. Six claims are made for the coupling described and several modifications.—No. 5864. April 5th, 1889. 8*d*.

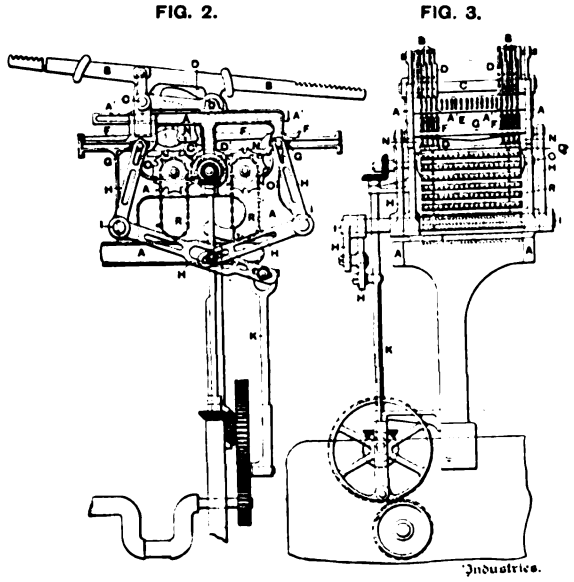
Steam Engines.—*L. Bénier, Paris.*—The inventor describes a novel form of steam engine and boiler. The boiler or evaporating apparatus is based on the following combination:—1. Making the boiler of cast iron; 2, causing the water to be delivered at the top of the boiler; 3, making the water run in thin streams over all or a part of the inside walls of the boiler and removing the excess. In the Figs. 1, 2, and 3 the boiler and engine are shown. The boiler is placed within a cast-iron frame H isolated from the hot gases and from the furnace by a lining of refractory earth. The boiler is formed of four similar parts M, but the number may be varied. Each part M is formed of cast iron provided on its exterior with vertical ribs, between which pass the heated gases from the furnace. The parts M are provided with internal horizontal passages N, each passage communicating at one end with the passage immediately above it, and at the other end with the passage immediately below it, so that on water passing into the upper part through the pipe O it traverses successively all the passages N and passes out through the pipe L in the form of steam, which pipe conveys it to a collector P. A door F, fixed by bolts to each end of each part M, allows of the conduits being inspected and removed. The small feed pump I continuously forces water into the boiler during the working of the motor; its discharge is calculated so as to introduce the necessary quantity of water to enable the required quantity of steam to be produced for keeping the engine working at the normal speed, otherwise there would remain water in excess. Further, the supply of water introduced can, in this case, be decreased by any suitable means. The water forced in by the pump passes through the pipe G to a collector J, whence the small pipes O conduct it into the series of passages M, the total section of the small pipes O being smaller than that of the pipe G; each series M receives the same quantity of water.



The motor, which is specially constructed to be combined with the boiler just described, is arranged to receive in the cylinder the mixture of water and steam coming from the boiler. The cylinder is vertical and open at its upper part. The piston is very long and forms a slide, and is connected directly by a connecting rod to the driving shaft which is carried in brackets cast on the frame H. The distributing valves, that is to say, the inlet and outlet valves, are represented by two slide valves not enclosed in a box.

Digitized by Google

The inlet openings, and especially the outlet opening, should be placed at the lower part of the cylinder to allow of the water introduced escaping easily. In some cases the two slide valves may be replaced by two other valves. The speed can be regulated as in an ordinary steam engine by a governor which operates a valve or other suitable regulating device. Claims: (1) A boiler in which the water introduced at the upper part flows in thin streams over the whole or a part of the walls of the boiler, the heated surface being provided with ribs, the boiler being constructed of one or more series of tubes such as M; (2) the combination of the boiler with the motor.—No. 20753. December 24th, 1889. 8*d*.



SHEDDING MOTION FOR LOOMS.—*S. Walker & G. Leek, Radcliffe, Lancashire.*—The object of the invention is to provide pattern shedding mechanism for looms for weaving various kinds of fancy cloths, having a positive up and down motion of the "jacks" or levers which actuate the healds. In the illustrations Fig. 1 is a front elevation of part of a loom fitted with the

FIG. 1.

improved mechanism, Fig. 2 is an enlarged view of the same, and Fig. 3 a side elevation of the same. As each "jack" or lever B is alike and actuated by similar mechanism, a description of the working of one "jack" will suffice for all. The "jacks" B are supported upon the shaft C in the frame A, and are raised and lowered by means of a roller fixed to a projection on B, and working in the groove of a cam D. The cam, which has a to and fro motion in a horizontal line, is supported by the slides A^1 in the guide bars E. To the underside of the cam D are secured two hooks F, which point in opposite directions, and engage in reciprocating sliding knives or bars G as required. The motion of the sliding bars G is produced by the bell-crank levers H, which are pivoted to the frame at I, and have an oscillating motion transferred to them, through the connecting rod K, from a moving part of the loom. The hooks F rest upon the ends of a bar or lever N, which is held down upon its fulcrums C^1, D^1, by a spring at its centre; its ends are raised and lowered by pattern chains R upon the barrels O. The pattern barrels are revolved by suitable gearing as shown. The action of the mechanism is as follows:—The slide knives G are continually oscillated in their guides by the levers H, but normally do not engage with hooks F. As the pattern chains, however, are revolved upon their barrels O, the pins in the chain raise and depress the ends of lever N upon which the hooks F rest. By

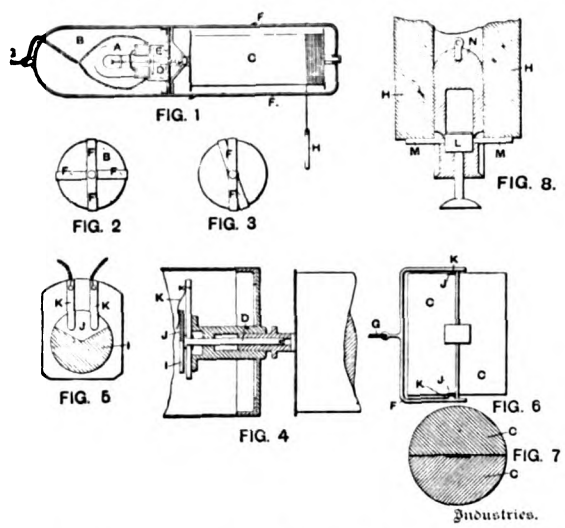


FIG. 2. FIG. 3.

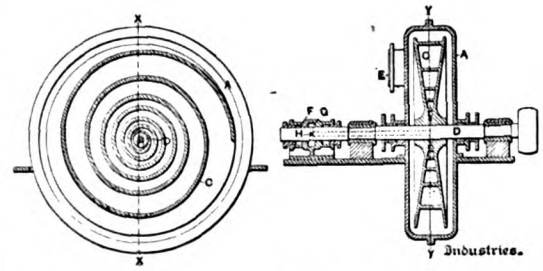
these means the hooks upon the depressed end engage with one of the sliding knives G and shift the cam D, thus raising or lowering the "jack" B. Claims: (1) A shedding apparatus or mechanism for looms having a reciprocating sliding cam or tappet to actuate the "jacks" or heald levers moved as required by two continuously reciprocating knife bars with which two hooks carried by the cam are caused to engage by the pattern chains substantially as and for the purpose described; (2) a shedding apparatus or mechanism for looms having a reciprocating sliding cam or tappet to actuate the "jacks" or heald levers, two hooks attached to the cam or tappet one at each side, two continuously reciprocating sliding knife bars G to engage with the hooks and give a motion to the sliding cam in both directions as required by the patterns, and two pattern barrels O and chains R substantially as and for the purposes described; (3) a shedding mechanism or motion for looms for weaving fancy cloths constructed and arranged substantially as herein described and shown.—No. 4757. March 19th, 1889. 11*d*.

PIPE FLANGES.—*E. Edwards, London.* (*R. Weyher, Arnstadt.*)—The improved flange is so constructed that it may at any time be removed from the pipe, and replaced by another without injury and without taking the pipe from its place and position. The flange is composed of two halves exactly similar to each other. If the flange is of a round shape, each half would be in the form of a disc having holes pierced in it for the bolts and pipe. The central hole for the pipe would be cut away upon one side to permit the flange being passed over the pipe. The part cut away would be of a wedge shape, and a thickened portion of the opposite half of the flange is made to fit the space so formed. Thus the flange would appear to have the parts cut out of one half attached to the corresponding face of the other half. The halves of the flanges are secured to each other and to the pipes by bolts. Claim: A pipe flange, consisting of two halves of the same shape, each having a recess and a raised wedge-shaped part fitting into the recess of the other half, the said halves being so put together as to leave between them the aperture for the pipe and to be secured to each other and to an adjoining pipe flange by means of bolts.—No. 6693. April 18th, 1889. 8*d*.

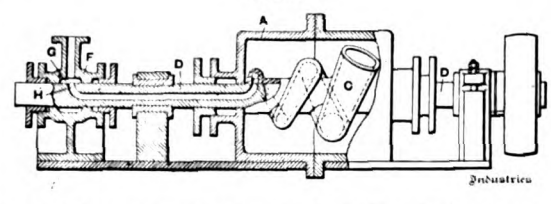
OBTAINING SOUNDINGS AT SEA.—*W. H. Schwartz, London.*—An appliance is here described by which soundings may be taken at sea whilst the vessel from which the operations are conducted is in motion. It consists of a floating device containing the sounding line and controlled by electricity from the vessel. In the illustrations Fig. 1 is a side view partly in section, Figs. 2 and 3 end views, and Figs. 4 to 8 modifications. To the water-tight casing B is attached the frame F for partly supporting the drum C carrying the sounding line. A magnet and coils A are fixed in the casing B. E is an armature in proximity to the poles of the magnet, the spindle of the said armature passing through the stuffing box or bearing D and engaging with the spindle of the drum C. The sounding line (which may be a thin wire or string) is coiled on the drum C and carries the weight or sinker H. The descent of this weight causes the drum and therefore the armature E to revolve before the poles of the magnet A, thereby generating alternate electric currents, which are conveyed by insulated wires from the coils of the magnet A to and through the cable G and thence to a suitable recording instrument on the vessel, by which the number of revolutions can be ascertained by reference to a scale, and consequently the depth of the water in which the sinker has fallen.



Or electricity generated upon the vessel may be used and a circuit completed and broken at each revolution of the drum C by a device such as shown in Figs. 4 and 5. In this case the spindle D carries a disc I with an insulating piece J by which the current between the terminals K is broken at each revolution. A further modification of this system is shown in Figs. 6 and 7. To more readily rewind the wire upon the drum C after a sounding has been taken, the weight H may be disconnected on reaching the bottom by a device such as shown in Fig. 8. The pusher L is forced up by contact with the bottom, and the arms M thus permitted to drop and release the part N from the weight H. Claims: (1) In apparatus for obtaining soundings of depths from ships or vessels in motion a buoy or float supporting the sounding line and connected to the ship or vessel, and means for indicating the length of sounding line payed out, so that a vertical or approximately vertical descent of the sounding line is obtained with the ship or vessel in motion; (2) in apparatus for obtaining soundings of depths from ships or vessels in motion the combination of a float and drum for the sounding line with means for indicating the length of line payed out.—No. 3197. February 22nd, 1889. 8*d*.

PUMPS.—*T. Eddleston, Pleasington, Lancashire.*—This pump is designed for agricultural purposes, being of simple construction and not liable to become blocked by solid matter suspended in the fluid. The pump is immersed in the liquid to be raised. Its barrel is placed horizontally, and its two discharge pipes, passing upwards, join the main at the same point, so that the discharge pipes and the barrel form a triangle. At the end of the pump barrel are flap-valves, which open directly to the body of fluid to be raised. The discharge pipes are also fitted with flap-valves. In the barrel is a piston for drawing in the liquid and forcing it up the discharge pipes. The piston is oscillated by a hand-lever which is pivoted to the piston rod and to a bracket attached to the pump barrel and one of the discharge pipes. One claim is made.—No. 6976. April 26th, 1889. 8*d*.

AIR PROPELLERS.—*B. & J. B. Verity, London.*—The apparatus is composed of an axle having radial blades secured to it, and the blades encased in a cylindrical casing, which is attached to and revolves with them. The blades are substantially of a screw form similar to that of a ship's propeller, so that when revolved the air is screwed forward and not forced by sudden concussion. Three claims are made for the form of blade described and the surrounding casing in air propellers.—No. 7017. April 27th, 1889.



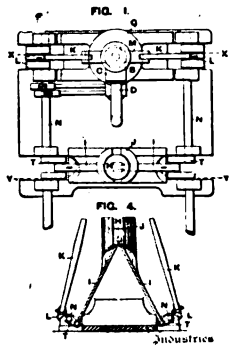
ROTARY ENGINE.—*A. A. Garside, London.*—In the revolving part of this engine there is formed a spiral passage which tapers from the centre outwards. Steam is admitted to the centre of this passage, and in its motion outwards causes the part to revolve. In Figs. 1 and 2 is shown one form of the apparatus, the figures being sections upon the lines X X and Y Y, and in Fig. 3 is shown a modified form. The revolving part C is fixed to hollow shaft D, through which steam is admitted to the centre of C as shown in Fig. 1. A suitable block supplies the means of admitting steam to the shaft as the shaft revolves. The part C is encased in a chamber A provided with the steam outlet E. This improved motor works in the following manner: Steam is supplied from a steam generator to the chamber G of the block F and passes through the orifice H along the centre of the shaft D to the centre of the spiral

FIG. 1. FIG. 2.

passage C. From the centre of C it travels to the outer part, expanding and causing C to revolve with its shaft D. The steam finally enters the chamber A, and is then drawn off to the condenser through E. Claims: (1) In a motive-power engine worked by means of an expansible fluid the use of a hollow spiral C fixed to a shaft, spindle, or drum D, and enclosed in a chamber E; (2) in a motive-power engine driven by means of an expansible fluid

FIG. 3.

the use of one or more hollow spirals C of gradually increasing area and fixed upon a shaft, spindle, or drum D; (3) the combination of a hollow spiral C secured to a partly hollow shaft D with a chamber A, bearings, and box F as described; (4) an engine, whose motive power is an expansible fluid, arranged and constructed substantially as set forth in Figs. 1 and 2; (5) in a motive power engine driven by an expansible fluid the use of one or more hollow helices C of gradually increasing area and secured upon a shaft, spindle, or drum D; (6) an engine whose motive power is an expansible fluid arranged and constructed substantially as set forth in Fig. 4.—No. 5619. April 2nd, 1889. 8*d*.



SIGNALLING ON RAILWAYS.—*W. Holland, Worcester.* (*S. P. Wood, Newport, Victoria*).—This invention refers to visible signalling apparatus for railway and other purposes of the kind in which a lamp is used in conjunction with discs or targets. According to this invention, the lamp is made stationary, and the targets, fitted with pieces of coloured glass, are secured to a carriage capable of being revolved about the lamp. The lamp, which is of ordinary construction, is secured to a stud at the top of a standard. The target carriage is supported by this stud. In a slot in the target carriage passes one end of a lever, which is pivoted to the side of the standard; to the other end is jointed an actuating rod, the arrangement being that by actuating the lever the target carriage can be revolved and the glass portion of the targets made to cover the apertures of the lamps as required. The actuating rod may be worked from any suitable apparatus such as the points of the line. Claims: (1) The construction of an indicating disc signal for railway and other purposes with a stationary lamp, a carrier, and a target or targets, in such a manner that when the carrier is actuated the lamp will not turn with the target or targets, but will remain stationary; (2) refers to the signalling apparatus as illustrated in the specification.—No. 6607. April 17th, 1889. 8*d*.

STOPPERS FOR BOILER TUBES.—*G. M. Key, London.*—One feature of this invention is that the insertion of the stopper cuts off the steam and water from the end introduced and so protects the operator. The stopper comprises a central bolt, upon which is threaded two pairs of collars at the ends and a distance tube between the pairs of collars. Between each pair of collars are placed elastic washers made of vulcanised india-rubber or such like material. These washers are so moulded as to have concave and convex surfaces. The concave surfaces face each other, and the convex are in contact with the collars. Between the elastic washers are thin metal discs. The collars are shaped so as to be easily entered into the tube, and the one nearest the operating end has a flange which covers the end of the tube and prevents the outrush of steam and water. When the stopper is inserted the bolt is screwed up and compresses the elastic washers between the collars, causing them to expand radially and stop the tube. Claims: (1) Effecting the closing and sealing of burst boiler tubes and the like; (2) the use of woodite, whaleite, asbestos, and vulcanised rubber with other material or materials; (3) that is formed in such a shape as convex and concave surfaces with bevelled edges or its equivalent arranged in manner such as herein set forth and operating for the purposes specified; (4) the construction and arrangement as herein set forth.—No. 3809. March 5th, 1889. 8*d*.

PIG IRON CARRIER AND BREAKER.—*R. B. Sparrow, Askam-in-Furness.*—The carrier consists of one or more endless bands and rollers, the latter being fixed along the pig bed and driven at any desired speed. At the end of the carrier is an elevator, having an endless band provided with metal brackets or hooks. The bands of the carrier and elevator are composed of iron or steel wire, chains, sheets, or any other suitable material. The pigs are placed upon the carrier and are conveyed by it to the elevator, whose metal brackets or hooks pick them up and raise them to the top of the elevator. As the endless band passes over the top pulley of the elevator, the "pigs" fall from brackets upon a breaker of the usual diamond shaped or any other suitable design to break the "pigs." The breaker is preferably constructed of steel. The broken pieces of iron may be conveyed away from the breaker by suitable shoots to a distance, from whence they can be safely removed. Claim: The combination of a horizontal conveyer with a vertically inclined elevator for the purpose of conveying, elevating, releasing, breaking, and distributing the fractured portions of pig iron as described.—No. 5049. March 23rd, 1889. 6*d.*

COMPOUND ENGINES.—*J. A. Clarke, Canada.*—This invention relates to compound tandem engines, specially designed for driving twin propellers. In the illustrations Fig. 1 is a plan of the engines, Fig. 2 a side elevation, Fig. 3 a sectional end elevation upon the line X X, and Fig. 4 a sectional end elevation on the line Y Y. The operation of the engine is as follows: Live steam passes into the steam chest C, through inlet pipe D, and operates the piston in the high-pressure cylinder B, while the exhaust from the latter acts on the piston in the low-pressure

cylinder G. The piston rod F thus receives an up and down motion by the action of the steam in the cylinders B and G, and as it is connected by its cross-head M, rods K, and the cranks L with the shafts N, the latter are rotated in opposite directions. The rotation of the crank shafts N works the slide H up and down in the guide ways J by the cranks T and connecting rods I. By this method of coupling the shafts N together, the power exerted upon each is proportional to the work performed by each. The improved engine, as above mentioned, is especially designed for marine purposes to drive twin screws, secured directly on the crank shafts N in front of the cranks T. In case

one of the screw propellers should become disabled, the power imparted to its shaft will be directly transmitted to the other shaft by means of the cranks T, the connecting rods I, and the slide H. In a heavy rolling sea one of the propellers frequently gets partially out of the water while the other is deeply submerged, and when this happens the slide H will prevent the flying around of the one propeller and will assist the other. It will be understood that as the cross-head M is secured directly on the piston F, and the rods K are directly connected to the said cross-head, no guide ways are used, thus economising power which would otherwise be lost in friction, and affording other attendant advantages. Three claims are made.—No. 20,988. December 31st, 1889. 8*d.*

GAS ENGINES.—*A. E. Tarernier & E. Casper, London.*—By a method described in this specification the engine cylinders are kept cool by converting water into steam. The cylinder is provided with a double jacket, but, instead of causing water to merely circulate therein, the double envelope becomes a boiler. The steam produced is conducted to a coiled pipe condenser. A suitable valve regulates the pressure at which the steam is allowed to escape from the jacket, and so regulates the temperature of the water surrounding the engine cylinder. The coils of the condenser are kept cool by a current of air, preferably that used for exploding the gas. Claims: (1) Cooling the cylinder of an engine operated by an explosive mixture by means of steam generated in a jacket surrounding the cylinder by the heat due to the explosives; (2) in an engine operated by an explosive mixture the combination of a jacketed cylinder with a pump for introducing water into the jacket in such quantities that it can be vaporised, a condenser for condensing the steam after it leaves the jacket, and a reservoir into which the water of condensation flows and from which it is withdrawn by the pump; (3) in apparatus of the kind described for cooling the cylinders of engines operated by explosive mixtures, cooling the condensers by means of air currents; (4) in apparatus of the kind described for cooling the cylinders of engines operated by explosive mixtures, the arrangement of mechanism as illustrated in the patent specification.—No. 7069. April 27th, 1889. 8*d.*

HYDRAULIC TRANSMISSION OF POWER.—*G. Pinnington, Chester.*—This invention may be understood from the following claims: (1) The duplication of pipes or tubes in the hydraulic transmission of power, whereby fluid is retained in the said pipes or tubes, and not discharged or lost after conveying power through or by means of subsidiary engines or machines, but is returned to the central station or stations and engines to be used again for the transmission of power to subsidiary engines or machines, side pumps being used as forcing pumps to supply the pipes or tubes with extra fluid to compensate for leakages; (2) it is evident that the fluid used in the pipes or tubes under pressure and conveying power may be specially mixed, or compounded, with a view to prevent sediment, or corrosion of metal, or to act as a lubricant, and this is claimed as a distinct feature of this invention.—No. 6400. April 15th, 1889. 6*d.*

STEAMSHIPS.—*A. H. Lucas, St. Louis, U.S.A.*—The improvements consist of an adjustable keel and supplemental hulls, which are simple and effective in their construction. The main hull has supplemental hulls fixed to each side of it. Between the supplemental hulls is the adjustable keel. The keel consists of a beam extending the entire length of the vessel. It is connected to the vessel by several posts, in the form of racks. These posts pass upwards into the main hull of the vessel, through cylinders with open ends, the top ends being of sufficient height to be above the level of the surrounding water. The racks are geared to pinions, by which they and the keel can together be raised and lowered. Three claims are made.—No. 496. January 10th, 1890. 6*d.*

ELECTRICITY.

DRIVING ELECTRICAL VEHICLES.—*A. Dickinson, Darlaston, Staffordshire.*—In this system the whole of the gearing is carried in pitch line and independently of the frame which carries the car body. The gear is mounted in a frame which is supported by the bogie axles. One end of the frame is pivoted to one bogie axle and the other end is mounted upon the other axle by a radial axle box, so that this end is free to rise and fall. The radial axle box is fitted with coiled springs, which tend to hold the frame in a horizontal position midway between its upward and downward freedom. The motor shaft is mounted in the centre of the frame parallel to the bogie axles, and carries a small pinion which gears by intermediate wheels secured to countershafts with spur wheels upon the bogie axles. The magnets, the armatures, the countershafts, and all the gearing except the helical wheels on the bogie axles, are mounted upon the frame, causing the whole to be in a sensitive elastic connection with the bogie wheels. Claims (1) The improvements in the mode of driving electrical vehicles by which greater steadiness is obtained; (2) in vehicles driven by electricity the extra frame for carrying the mechanism as described; (3) in vehicles driven by electricity the use of helical gear mounted substantially as described.—No. 18638. November 21st, 1889. 6*d.*

ELECTRIC RAILWAYS.—*G. E. Vaughan, London.* (*S. Trott, Nova Scotia.*)—This invention refers to the brush contacts of electric railways, the inventor's object being to more effectually insulate the conductors connected with the contact brushes, to protect them from injury, and to provide the conductors and brushes with an efficient carrier. The conductors are encased in insulating material, and at the point where the brushes are attached to their holders the insulating material is spread out into hoods, which protect the brushes from falling moisture, the brushes being arranged vertically to make contact with the upper surface of the conducting rail. The two insulated conductors are enclosed in a carrier which travels in the slot of the conduit enclosing the conducting rails. The carrier is formed of two thin plates between which the conductors are clamped. Between the ends of these plates are screwed thick vertical plates which act as a plough or clearer for the slot. These several plates are secured together by means of two solid horizontal plates upon each side of the upper part of the carrier and firmly connected together by bolts passing through them and the end plates. The carrier is supported from the car by means of swivels attached to the ends of the horizontal solid bars. By these means the carrier is flexibly connected to the car, and it is pressed down on to the conducting bar by coiled springs. Three claims are made.—No. 7127. April 29th, 1889. 8*d.*

CHEMISTRY.

NON-CORROSIVE MATERIAL.—*B. Rhodes, London.*—This is an acid-resisting material of the following composition:—Para rubber in solution 25 per cent., asphaltum in solution 5, albocarbon in solution 5, mica in fine powder 20, flower of sulphur 3, and talc in fine powder 2. These ingredients are thoroughly mixed together, and a solvent, such as rectified spirit, added, until the mixture is about the consistency of cream. To this mixture is added 40 per cent. of the strongest fibrous asbestos, and the whole is then kneaded together. The material thus formed may be rolled into sheets and dried, producing a felt suitable for jointing, &c.; or it may be passed through rollers with sharp spikes, or otherwise teazled out into a substance resembling tow, which when dried may be used for caulking. The proportion of rubber and sulphur may be increased, so as to form a more elastic and flexible material. Claims: (1) The coating or covering of fibrous asbestos with mica and talc, or either of them, by the aid of vegetable gums in solution, to form an acid-resisting packing or jointing material for the purposes set forth; (2) non-corrosive packing or covering materials as described.—No. 5363. March 28th, 1889. 4*d.*

GENERATION OF HEAT IN FURNACES.—*H. H. Lake, London.* (*E. B. Cornell, Philadelphia, U.S.A.*)—This invention relates to the generation of heat through the agency of steam. Heretofore it has been customary to increase the heat in furnaces by increasing the consumption of fuel by increasing the draught or supply of oxygen. The method most closely resembling the invention is that in which steam and air is injected upon the fuel. In this method, the heat necessary to dissociate the steam greatly counteracts the extra heat produced. In the present method of dissociating the steam, the steam is passed over iron or similar material that will absorb the oxygen, setting free the hydrogen to be used as fuel. The principle of the invention is based upon the discovery that steam passed through a cast-iron tube, maintained at or above the temperature of molten silver, is decomposed into its constituent gases without oxidation of the tube. The action cannot be obtained with plain wrought-iron tubes for the reason that the wrought-iron tube is rapidly oxidised. Cast-iron tubes are therefore used, these tubes being rendered non-oxidisable for the supposed reason that they are coated with a stratum of carbide of iron or carbon-silicide of iron. In the practical use of this action, the dissociating tubes are placed in the hottest part of the furnace of the boiler. The steam is passed through these tubes, and the gases so formed conducted by pipes to the closed ashpit of the furnace. If coal is being burnt in the furnace, the water gases in their passage to the ashpit are made to induce a draught of air sufficient for the combustion of the fuel. Twelve claims are made.—No. 20986. December 31st, 1889. 8*d.*

SUBSTITUTE FOR IVORY, &C.—*F. Greening, London.*—The substitute is prepared from any suitable fibre or cellulose matter such as cotton combings, paper, esparto grass, or rags. These are treated with a mixture of nitric acid of about 1,420 sp. g., and sulphuric acid of about 1,840 sp. g., in the proportion of about 30 per cent. nitric acid. The fibre is thoroughly saturated with the mixture, and then the excess is allowed to drain off. After this treatment it is kept in a warm atmosphere for one hour, when the conversion will have taken place. The mass is now well washed in water to free it of any remaining acid, and is then submitted to a bath of sodium chloride and ammonia alum in the proportion of 75 per cent. ammonia alum. The material thus obtained is dried and dissolved in a solvent prepared by distilling acetate of lead and anhydrous lime in the proportion of two parts by weight of acetate of lead to one of anhydrous lime. The distillate produced is mixed with fusel oil, and when thoroughly mixed a purifying agent such as phosphoric chloride is added and the mixture again distilled. In this solvent the treated fibre is dissolved, producing a plastic material which, when dry, may be used as a substitute for ivory, &c. Claims: (1) Treating fibrous substances with a mixture of nitric acid and sulphuric acid, and after washing the product submitting t to a bath of sodium chloride and ammonia alum for the purpose of producing a soluble base as and for the purposes described; (2) the manufacture and use of the described solvent, such solvent being produced by distilling a mixture of acetate of lead and anhydrous lime, fusel oil being added to the distillate and also a suitable purifier; (3) treating the base forming the subject of claim 1 with the solvent forming the subject of claim 2 as and for the purposes described; (4) the manufacture and use of an improved material adapted to be used for a variety of purposes, substantially as hereinbefore described.—No. 5344. March 28th, 1889. 6*d.*

MISCELLANEOUS.

COATING IRON PLATES.—*W. E. Everitt, Birmingham.*—In coating plates and sheets of iron with copper or brass by the method constituting this invention, the plate or sheet is freed from rust and then covered by a thin layer of finely granulated hard solder with an addition of finely powdered borax. The sheet of copper or brass with which the iron is to be coated is then laid upon the hard solder and borax, and the whole exposed to a bright red heat. The solder and borax are thus melted, and pressure being applied the sheet of copper or brass adheres to the surface of the iron. The apparatus employed in this process consists of a furnace with openings upon opposite sides. The sheets of metal prepared with the layer of solder and borax are passed in at one opening of the furnace, and, when sufficiently heated, drawn out at the other and passed between a pair of rolls, which finish the process. Claims: (1) Coating plates and sheets of iron with plates or sheets of copper or brass by interposing between them a layer of mixed granulated hard solder and borax, and exposing the said plates and the mixture between them to a bright heat and applying pressure to the heated plates as described; (2) constructing a furnace having openings at opposite sides and combining therewith a pair of cylindrical rolls to be used in conducting the coating process claimed in the prior claim.—No. 4335. March 12th, 1889. 6*d.*

DRAWING METALLICALLY COATED METALS.—*W. A. Thoms.*—The chief object of this invention is to produce compound wires suitable for use in electric incandescent lamps. For this purpose the core of the wire is composed of steel or iron, and the coating of platinum, gold, or aluminium The iron (say, No. 20 standard wire gauge) is carefully cleaned, and then coated by any of the well-known methods with a metal such as tin or gold which will prevent the oxidation of the core in the succeeding operations, and assist its union with the incorrodible metal. The wire thus prepared is inserted into a tube of platinum and attached at one end. The length of platinum covered wire is then submitted to the well-known method of drawing, by which means the component parts are drawn out to the required length and joined together. Claim: In the manufacture of drawn or rolled metallically coated metal articles, the preparing of the core (whether in a solid or hollow form) by the application of tin, gold, or other non-oxidisable metal as described, for preventing the oxidation of the core metal during the process of working, and to increase the cohesion of the core with the metal employed to form the covering or envelope for the core.—No. 908. January 17th, 1890. 4*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

GRIPPER PLATEN PRINTING MACHINE.

THERE was shown at the recent Ironmongers' Exhibition a gripper platen printing machine made by the Godfrey Printing Machine Company, 69, Old Street, E.C. The machine has been for many years in the market, but has been lately improved, and an illustration of the most recent type is given herewith. Speed is its great feature, 2,500 sheets per hour being passed by it. There are four sets of grippers moving round the platen. While one impression is being made, a sheet is taken by one of the rows of grippers, and while this is advancing another is caught, and so on in rapid succession. The platen can be turned over into a convenient position for making ready, and the machine is self-delivering. The whole of the movements are automatic, and to work it no skilled labour is required.

THE MANUFACTURE OF BASIC PIG IRON.*

THE rapid extension of the basic process, both in the Bessemer, Siemens, and other types of furnaces, and the certainty that from various causes the manufacture of steel or ingot iron by this process will be of much greater importance in the future, and that the production will be in much greater quantities than at present, must of necessity render the question of producing suitable pig iron one of paramount importance. When we reflect that the supplies of hematite ores of steel-making qualities are comparatively limited, and moreover that these supplies are only available in very few localities, it will at once be seen that the basic process to us assumes great importance, and affords us a means of converting the unlimited supplies of phosphoric ores in this country into steel. The absence of hematite ores of suitable quality in Germany, and the cost of importing those ores or Bessemer pig iron, has caused an extraordinary development of the basic process there, and we can have no better illustration of its value than that afforded by Germany. I need scarcely point out to this Institute that, to us in this district, where the cost of transit all but precludes the use of hematite pig iron, if steel is to be made at all, the basic process is the process best suited to our requirements. Our supplies of suitable materials are plentiful, and the success of the process in open-hearth furnaces gives us a convenient furnace for this district, and for the arrangements of our works and our particular manufactures. As the results obtained in the basic process depend to a considerable extent upon the quality and regularity of the crude iron used, and as I have had some amount of experience in its manufacture, it has been thought that some few remarks upon it may not be deemed uninteresting.

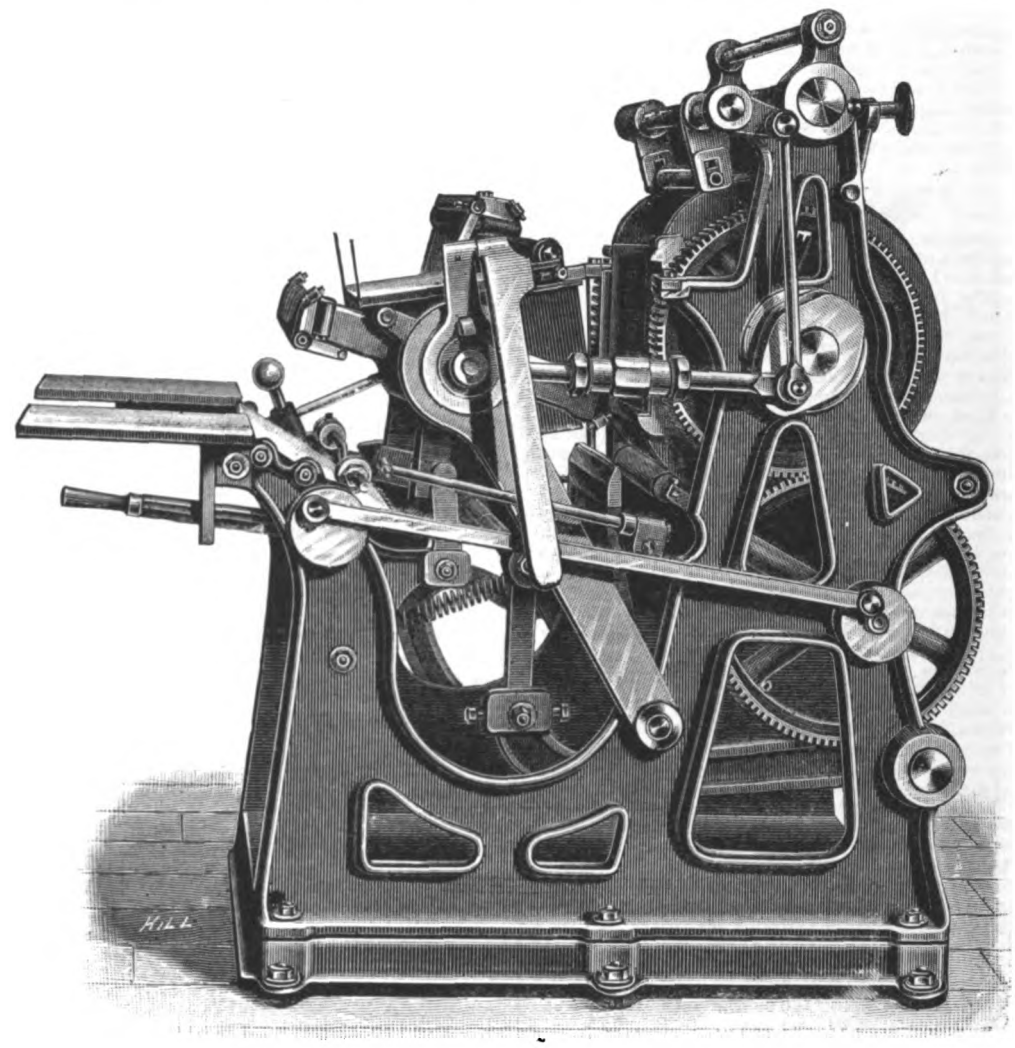
When first introduced, the basic process (like many other processes) promised very wonderful things; almost any pig iron was suitable, provided it only contained plenty of phosphorus. I find that in 1882, at this Institute, one of the patentees of the basic process said, "As regards the composition of the pig used, great fluctuation is permissible; thus, the silicon may vary from 0·5 to 1·8 per cent.; the phosphorus from 1·8 to 3·0 per cent.; the sulphur from 0·08 to 0·3 per cent.; and the manganese from 0·5 to 2·5 per cent.;" it was therefore proposed to use the common cinder pig of the district. In the experiments made by a syndicate, selected pigs were used of the following composition:—

	Strong Forge.	Strong Forge.
Manganese	1·12	1·77
Silicon	1·17	1·17
Sulphur	0·08	0·05
Phosphorus	2·97	4·40

For some considerable time, common white or mottled cinder pig was used in Staffordshire, very often produced indiscriminately when furnaces were out of order, a typical analysis of which would be—

Manganese	1·35
Silicon	1·50 to 2·00
Sulphur	0·10 to 0·20
Phosphorus	3·50 to 4·00

I am not aware that such a feat as this was ever attempted in any other district. It was very soon found, however, that such metal was unsuitable, the waste and wear and tear being enormous, to say nothing of the quality of the steel produced from it. It is wonderful, however, with what tenacity some steel makers stuck to this material even up to a recent date. It has been, however, of late years, largely substituted by other and more expensive pig iron.



In the Cleveland district, in the early days of the basic process, ordinary grey Cleveland iron was used, which, as you are aware, does not contain more than about 1·5 per cent. of phosphorus; the silicon being over 2 per cent. Afterwards, several brands were mixed together, often with a little spiegel; then, as the necessity for lower silicons became apparent, forged and mottled or white iron were used; the drawback to white iron being its high sulphur. Finally, it became apparent that it would be convenient and expedient to combine all these results in one pig, the required manganese being an aid to the manufacture of such a white pig, low in both silicon and sulphur. Such a pig is a basic pig. One of the first basic pigs made in this district contained—

Manganese	2·00
Silicon	2·50
Sulphur	0·06
Phosphorus	2·95

* Paper read before the South Staffordshire Institute of Iron and Steel Works Managers, by Mr. Herbert Pilkington, F.C.S., M.I.Mech.E., Vice-President, on the 15th ult.

GRIPPER PLATEN PRINTING MACHINE.

CONSTRUCTED BY THE GODFREY PRINTING MACHINE COMPANY, LONDON.

But those made at the present time will vary at different works, as under:—

Manganese	2·0
Silicon	0·4 to 1·2
Sulphur	0·05
Phosphorus	2·5 to 3·25

I also add a table of analysis of basic pigs at works in other districts:—

	N. Staffs.	N. Wales.	Middlesbro.	France.	Germany.
Manganese	2·50	1·75	2·25	1·50	1·50
Silicon	0·25	0·40	0·74	0·75	·60
Sulphur	0·05	0·04	0·04	0·06	·06
Phosphorus	2·84	3·00	2·60	2·00	2·00

It will thus be seen that different steel works have different requirements; but, speaking generally, in this district a basic pig is a pig which must be low in silicon and sulphur. Over 1 per cent. silicon or 0·10 per cent. sulphur would be objected to, and half that quantity would be considered a good pig. It should contain about 1·5 per cent. to 2·0 per cent. of manganese and 2·5 to 3·00 per cent. of phosphorus. Whether it would not be better to work with less phosphorus than 3 per cent. I must leave entirely to steel makers. The value of such a pig for forge purposes should be very great indeed, as it cannot but be economical to use, as a mixture, a pig so low in silicon and sulphur, and containing so much manganese. I believe it has been tried to a limited extent, but I am not aware that it has been used regularly. In order to produce this pig it is necessary to work the furnace with a very basic slag, and also at such a temperature that the iron shall be white in order to keep the silicon low, and, on the other hand, sufficiently hot to keep the furnace in working order, and also to allow the sulphur to escape in the slag. In arranging the charges, therefore, this is the primary consideration; and keeping this in view, it admits of considerable latitude in the nature of the materials employed. I need not tell this Institute that tap cinder forms the principal part of the furnace burden, and the only limit placed upon its use is the quantity of phosphorus required in the pig. It is usual to use Northampton ore or pottery mine to reduce the phosphorus, the use of the latter having some little advantage, owing to the fact that it introduces a little manganese. Having regard to the character of the slag required, I have always found it an advantage to add ores to the charge that are of a basic character, and so reduce the use of added lime, &c., to a minimum; and indeed this principle should be kept in view in selecting any ore for basic work; not only is it economical as regards the fusibility and basicity of the slag, but it is also much less troublesome to work in the furnace. Such ores as these are not difficult to obtain, nor can they be deemed expensive. I give analyses of two such ores, one from the Lincolnshire district, and the other from the Oxfordshire district:—

	Lincolnshire.	Oxfordshire.
Ferric oxide	39·24	40·65
Ferrous oxide	trace	trace
Silica	13·04	7·24
Alumina	5·56	6·94
Lime	18·42	20·22
Magnesia	0·72	—
Magnesia oxide	0·63	0·40
Phosphoric acid	0·61	0·86
Sulphuric acid	trace	trace
Carbonic acid	11·26	22·65
Combined water	10·54	—
	100 03	98·96
Metallic iron	27·46	28·46

In order that sufficient manganese may be imparted to the pig, resource must be had to manganiferous or manganese ore, and I attach a great deal of importance to the selection of a suitable ore. It is infinitely better to use a manganiferous carbonate low in silicon than rich manganese ores, which often contain upwards of 20 to 35 per cent. of silica. Manganese has a most powerful affinity for silica, and where there is an excess of silica there is often a great loss of manganese in the slag, notwithstanding its being of a very basic character. On the other hand there is also a danger of the reduction of too much silicon into the pigs, there being very good ground for supposing that the methods of reduction of silicon and manganese are very similar. It is not always easy for the furnace manager to obtain accurate information about these ores, and the usual analyses are not always sufficient; few of them show the state in which the silicon exists, and I feel sure that a little work in this direction would be highly instructive. If the silica is in combination with the manganese, you have both elements in the most favourable state for passing into the slag unreduced, as the silicate has to descend the furnace until the reduction is effected by the solid fuel, where a portion of the silicate may easily escape reduction. On the other hand, the silica being liberated in the presence of highly-heated metal is very favourably situated for reduction into silicon in the pig, were it not that, generally speaking, the other and more powerful influence generally prevails. It is, of course, well known that many makers of basic iron use the slag made in the manufacture of spiegeleisen, which usually contains from 7 to 10 per cent. of manganese, as silicate. In some circumstances, of course, this slag is often the cheapest source of manganese available; but invariably it is found that the results obtained are not so satisfactory as if a good ore was used; a little variation in the furnace temperature, or the

Digitized by Google

composition of the charge or the slag, will send the whole of the manganese into the slag, and there is always a greater loss of manganese by its use. If a spathic carbonate is used, it must of necessity be calcined; and if properly calcined, all the elements in combination of whatever character will be liberated and will be then in a perfectly free state. I give the analysis of such an ore when calcined:—

Molland Ore.			
Ferric iron	54·55		
Alumina	4·05		
Manganese oxide	21·94	Metallic iron	38·19
Lime	2·00	„ manganese	17·00
Magnesia	0·78		
Phosphoric acid	0·38		
Sulphuric acid	0·20		
Silica	12·00		
Loss on ignition	3·00		
	98·92		

As the tap cinder of this district contains some amount of manganese, the addition of 5 per cent. of this ore to the furnace charge is usually sufficient to produce 2 per cent. of manganese in the pig. Incidentally, I may say that flue cinder is not used for basic pig, because of its silica; it being of the utmost importance to put as little silica into the furnace as possible. You will probably be aware that the tap cinder is usually calcined in South Staffordshire. As I have previously stated, the required furnace conditions are: a furnace sufficiently cold to keep the silicon low, and on the other hand, sufficiently hot to enable the slag to carry off the sulphur, that slag being a very basic slag for that purpose, as well as to keep the silicon down. This set of conditions could not be very easily complied with were it not that the use of manganese supplies the key to the whole situation. In the first place, it makes the iron both hot and fluid, and secondly, it greatly increases both the basicity and fluidity of the slag, which, although very basic, is through the presence of manganese fused at a comparatively low temperature, and it is therefore a slag of great fluidity, or, as a furnaceman would say, "a hot slag." The precise action of manganese in the slag, I take to be, in the absence of a better explanation, what I have already described in a previous paper, *i.e.*, that it exists as a silicate of manganese, the manganese replacing lime, and therefore leaving that much more lime free to carry off sulphur. The quantity of lime here liberated may be only small, but the total quantity of lime in the slag is large; moreover, the silicate of manganese increases greatly the basicity of the slag, and the temperature being comparatively low, the silica is dealt with readily as a silicate of lime, magnesia, alumina, and manganese, while the considerable amount of lime present can deal with the sulphur easily at that temperature which is sufficiently hot to allow it to be slagged off. It will thus be seen that the influence of temperature is very great, and that, other conditions being right, the regularity of the pig depends to a very considerable extent upon the care with which the furnace is managed, in keeping it in the happy mean between the two extremes, which I illustrate by the following analyses of pigs made in a basic furnace:—

	Hot Grey Iron.		Cold White Iron.	
Manganese	2·42	2·68	1·76	1·04
Sulphur	0·04	0·08	0·42	0·22
Silicon	2·09	1·93	0·57	0·71
Phosphorus	3·45	3·33	3·54	3·32

It may be said that many of the facts here presented are well known, and that although the manufacture of basic iron may require more care and presents more risk than in the case of ordinary pig iron, yet it presents no difficulties that may not be readily overcome. I am quite ready to grant all this when its manufacture is accomplished by means of good hard oven coke (such as Durham coke), but when this admirable material is replaced by soft gas coke and raw coal, I think that most furnace managers will admit that when these fuels are used in a furnace making white iron, and with a slag containing 40 to 46 per cent. of lime, those difficulties and risks are greatly increased. The following analyses may be taken as those of a typical slag where the fuel is good hard coke, and where the lime is usually kept at the utmost quantity the furnace will carry, and the manganese in the slag is reduced to a minimum:—

Slag.		Iron.	
Ferrous oxide	1·52	Phosphorus	2·79
Alumina	12·12	Sulphur	0·04
Manganese proto	2·10	Silicon	0·35
Lime	51·13	Manganese	1·90
Magnesia	·22		
Alkalies	·50		
Sulphur	0·89		
Phosphoric acid			
Silica	31·21		
	99·69		

In this district it is not possible to keep a furnace working very long with a slag containing 50 per cent. of lime when soft gas coke and coal are used. These fuels produce a large amount of dust, which in the case of a basic furnace accumulate to a large extent, and when the lime is very high causes great trouble at the tuyeres by cold noses, pocketing, chilling up in the hearth, &c. In the case of an ordinary furnace this dust is not so apparent; because with a hotter furnace and a silicious slag a considerable quantity of it is burnt and melted. The object to be aimed at under these circumstances is to work as hot as possible, consistent with low silicons, and to back up the lime by a little manganese in the slag. The following irons and slags were produced regularly under such circumstances:—

Slag.		Iron.		
Lime	46·20	Manganese	2·27	2·02
Magnesia	2·87	Sulphur	0·02	0·01
Alumina	9·97	Silicon	0·40	0·35
Silica	34·76	Phosphorus	3·20	3·19
Manganese proto	4·30			

The following is a slag made under somewhat different conditions, which produced a pig having 0·06 per cent. of sulphur and 0·89 of silicon; and this may be regarded as the most acid type of slag from which good basic iron can be made, as under no circumstances can more than 36 per cent. of silica be tolerated if the quality of the pig is to be maintained. It is somewhat exceptional in its contents of manganese oxide, the furnace being working rather hot at the time, a sample taken a few days previously containing 5·55 per cent:—

Silica	36·05
Alumina	8·72
Iron oxide	3·94
Calcium	2·66
Sulphur	2·13
Lime	39·60
Manganese oxide	1·80
Magnesia	4·48
Alkalies	1·20
	100·58

It will be readily understood that there is not a large margin of heat for the safety of the furnace, and I have known times when from dust accumulations, excess of lime, and coldness of the furnace, a "gob" has appeared imminent, having given very little warning of its appearance. I have usually in these circumstances immediately taken off a considerable amount of lime for a short time, when the furnace will often recover itself readily when the excess of lime has been worked off. The pig iron is not much affected by this treatment if the lime is replaced early enough, owing to the accumulation in the furnace. If a tendency to silting up appears, a little extra manganese will often correct it and prevent further accumulation. The trouble at the tuyeres is often considerable, and tuyere changing is frequent, and it is very convenient to have the furnace well fitted with tuyere valves, &c., in order to be able to shut off pocketed tuyeres with as little loss of time as possible. These troubles may, however, be avoided to a considerable extent by the use of a strong blast, a frequent use of the tuyere pricker, and a good hot slag, and, allow me to add, good management. As I have observed before, having all other things right, the principal point is to keep the furnace temperature constant, and the regular working of the furnace is then ensured. I cannot too strongly emphasise the fact, however, that in order to ensure regularity and good quality in the product, there must be a regular and systematic system of analyses of the fuels, fluxes, minerals, and slags; as not only does this save great trouble and anxiety in working, but also enables a pig to be produced more economically, and of a better and more regular quality, than if only intermittent analyses were taken. The fuel consumption when making basic iron is certainly not high if the furnace works well; it is then tolerably regular at 21 to 22 cwt. of coke per ton of iron, or its equivalent in coal or coke, with a blast at a temperature of 950° F. But if any silting up in the hearth or difficulties at the tuyeres occur, it often rises very much higher and continues high until the furnace returns to a normal state.

These remarks apply to furnaces 56ft. to 60ft. high, such as are prevalent in this district, producing 280 to 350 tons per week. If good hard coke were used most of these troubles and difficulties would be avoided, and the production of our furnaces much increased, and it is therefore to be hoped that the attempts being made in the district to produce such a coke may ultimately be successful, as from its freedom from sulphur, and other reasons, such a fuel would be a most valuable addition to the resources of South Staffordshire.

THE INSTITUTION OF NAVAL ARCHITECTS.

(*Continued from page* 316.)

The discussion on Admiral Colomb's paper, on the "Washington Maritime Conference," was opened by Mr. Baden Powell, who thought that the Conference had left the rule of the road at sea very much as before. The verdict of the mercantile marine was that the rule of the road can be done without, and that everything depends on the officers themselves.

Admiral de Horsey thought that accidents will happen with the best of management. The most fruitful causes were bad look-out, ignorance of the rules, and neglect of the rules. He thought that the risk of collision was from the opposite ship not changing in time. He had always understood that the ship which kept its course was bound to keep its speed also. The rules as they at present stood were certainly in bad English, and wanted some explanation.

Mr. McFarlane Gray, of the Board of Trade, said he once asked a captain after a collision what about his rules, and was told he had thought of them too late. This was adduced as an argument that the rules were of little value.

Admiral Bowden Smith, as a member of the Washington Conference, congratulated Admiral Colomb on his paper. The Admiralty experiments, previous to the Conference, were found very valuable, and the same might be said of what had been done at the recent manœuvres. What he thought was required was not so much alteration of the rules, but more supervision in carrying them out. When a ship held on her course, she did not know what the giving-way ship would do. What was wanted was that the holding-on ship should have her own way completely. Experiments had demonstrated that red lenses absorbed about 60 per cent. of white light and green 90 per cent.

Captain Wharton, the Hydrographer of the Navy, said that out of 45 collisions, 39 were due to want of intelligence on the part of those in charge. The crossing a ship's bows was the cause of almost all collisions.

Mr. Stromeyer considered many collisions were owing to the position of the lights, and in a diagram he explained that all the difference followed from the side light being well forward or not. Many captains asked themselves where the light was, because if considerably aft, there might be a very large angle made by the ship which would not show by the light at all, whereas the nearer the light was to the bow the more impossible it became for this difference to occur.

After remarks by other speakers Admiral Colomb replied. He thought some definite form of instruction should be given to our seamen on this all important matter. When he commanded a ship, it was his inflexible rule to give the order to stand by in the engine-room before he altered his helm. He was thus prepared for an emergency. The most frequent cause of collision was altering the helm too soon.

The next paper was read by Professor P. Jenkins on "The Strength of Ships, with Special Reference to the Distribution of Shearing stress over a Transverse Section.' We intend to publish this important paper in full in an early issue, together with the discussion which followed it.

Mr. Frank C. Goodall then read a paper on "Steatite as a Pigment for Anti-Corrosive Paint." How to efficiently protect the iron and steel work of our ships, bridges, and other iron and steel structures from rust and premature decay is a question which has long occupied the public mind; and up to the present time no complete or satisfactory answer has been forthcoming. For many years the author has had the impression that the mineral steatite, commonly known as "soapstone," if it could be incorporated in an elastic paint, would possess qualities incomparably superior to the metallic oxide pigments generally used; steatite when mixed as an ordinary paint, viz., with raw or boiled linseed oil, driers, turpentine, terebine, &c., neither mixes nor dries hard, and was quite useless as a protective paint. After further experimenting, and finding oil, driers, terebine, &c., would not act with steatite in the formation of a paint, the author wrote a letter to the press calling the attention of shipowners and paint manufacturers to the subject. Immediately afterwards he received numerous letters and calls in reference thereto. Amongst the first to visit him was a member of a well-known firm of paint manufacturers, who stated on their behalf that they had also experimented with steatite in the same direction, and that they had succeeded in embodying it as a pigment for paint with a quick-drying varnish; that their experiments up to date had proved that steatite as a pigment for anti-corrosive composition was a success, and that they had acquired patent rights for the combination. Subsequent experiments and trials by the author have shown their statements to be well founded. Steatite does not protect steel in the same way that a metallic oil paint protects it, but once properly applied to the true surface of the steel, it is indestructible, and there will be absolutely no rust on the parts coated with it. Varnish alone is porous, and admits the atmosphere and moisture to the body coated with it; but when mixed with steatite, owing to the minute atoms of which it is composed, the fine pores are completely closed, and the paint becomes air and water tight. It is thus that steatite answers the double purpose of enabling the composition to adhere to the steel, and to make it completely air and water tight. The varnish also is a non-conductor of electricity, so that no galvanic currents can be set up.

In the discussion which followed the reading of this paper, Captain Fairholme said the damage done by paints was due to the oxygen they contained. His plan was to use naphtha such as the gas factories supplied, as the ordinary oil produced rust. Steatite was suitable as a pigment, if his plan were adopted.

Mr. Martell said it was most important in connection with ships' paints that samples should always be brought forward. He did not agree that the ordinary oxide of iron paint was harmful. Why paints frequently peeled off steel ships was because the mill scale had not been removed in the first place. If this were done, the plates pickled, and the painting applied at regular intervals, steel was as good as iron in this respect.

The next paper was read by Mr. C. E. Stromeyer, on "The Distribution of Evaporation in a Marine Boiler."

This subject has not been dealt with at previous meetings of this Society, but I have been able to avail myself of some very interesting inquiries by Mr. D. K. Clark* and Mr. J. A. Longridge† into the distribution of evaporation of locomotive boilers. Naturally their chief interest centres on the question of the distribution over the length of the tubes, the diameters of these boilers being very much less than their lengths. In a marine boiler it often happens that we have combustion chambers high enough to stand in, while the tubes hardly exceed six feet in length, and it is very probable that there must be more gas (or products of com-

* Institution of Civil Engineers, Vol. XLVI., page 242.
† *Ibid.*, Vol. LII., page 101.

Digitized by Google

bustion) passing through the upper than through the lower tubes. This distribution is governed partly by the temperatures in the combustion chamber and smoke box, and partly by the resistance of the gas in the tubes, and this again depends upon the velocity and temperature of the gas, and on the loss of heat experienced by it. It will therefore be necessary to deal first with some of these problems.

The coefficient of transmission of heat through boiler tubes or combustion chamber plates found by Mr. Longridge is 11 cals. of heat per square foot per hour for every degree (Fahr.) of difference between the gas and the water: 0·91 is the reciprocal value of the above, and is the resistance offered to the flow of heat under the above condition. Now this resistance is composed of the resistance which is offered when heat passes from one medium to another—as, for instance, from the gas to the metal, from the metal to the boiler scale, or to the water—and it also includes the resistance offered by the metal and the scale. For iron, and for plaster of Paris, which latter is the same substance as boiler scale, the resistances are 0·00202 and 0·207 per inch thickness, so that a clean half-inch plate would offer 0·001 resistance, or, if covered with scale 1-10in. thick, the resistance would be $0{\cdot}001 + 0{\cdot}021 = 0{\cdot}022$. Comparing these values with 0·091, which is the value adopted by Mr. Longridge, we are driven to the conclusion that the chief resistance, about 80 per cent., is encountered at the surfaces. I doubt whether the change of medium from iron to scale, and to water, influences the above values very much, as it seems more than probable that the chief difficulty in transmitting heat from the gas to the tubes is the want of circulation, and the outer layers of the gas are not replaced sufficiently quickly by the inner ones, which are hotter. It ought to be possible to effect this by draught retarders or by using corrugated boiler tubes; and I also believe that the excellent results which have been obtained by the use of John Brown's ribbed tubes is simply due to the increased inner surface which is exposed to the gases, whereby the resistance is diminished from 0·091 to 0·055. If the above is the true explanation, then I believe that Mr. Longridge is not quite correct in adopting the same coefficient for the combustion chamber as for the tubes, because, in the former case, heat is imparted to the plates, not only by contact, but also by radiation, and, under these circumstances, a recalculation of his results would most likely lead to a higher value for the resistance of the tubes, and a lower one for the combustion chambers. That radiation plays an important part will be seen from the experiments by M. P. Havrez,* referred to by Mr. Clark. In one of his experiments coke was used, while in the other one briquettes were burnt, and it was found that there was relatively more heat absorbed in the firebox with the flaming material than with the flameless coke, and it is well known that a luminous flame radiates more heat than a non-luminous one, for which reason the latter may not be used in the Siemens-Martin furnace. For these various reasons, I believe that the formulæ used by Mr. Longridge for the heating of boiler tubes will be more correct if the coefficient of resistance $\frac{1}{m}$ is increased a little, say from 0·091 to 0·1, so that his formulæ would be—

$$t = t_0 \cdot \epsilon^{-\frac{10 \cdot S}{h}}$$

$$H = h\,t\left(1 - \epsilon^{-\frac{10 \cdot S}{h}}\right)$$

t = Difference between the temperatures of the boiler water and of the gas in the tube after having traversed S square feet of surface.
t_0 = Difference of the above temperatures before the gas has entered the tube.
ϵ = 2·718 . . .
$h = \sigma$. Q = Specific heat × Weight of gas (products of combustion) passing through the tube.
H = Quantity of heat transmitted through the walls of the tubes. This quantity divided by 1,150 gives the quantity of water evaporated from 60° F.

The coefficient 10 is the quantity of heat transmitted per hour, therefore the time units of h and H must also be the hour.

I intend to adopt the following values:—

$\sigma = 0{\cdot}236$.
S = π . D . L . = π . 3in. . 6ft. = 4·72 square feet.

Instead of Q, the weight of the products of combustion, I intend to use C = the weight of coal from which Q has been produced.

$$Q = 30 \cdot C \text{ nearly}$$

Then

$$t = t_0\,\epsilon^{-\frac{20}{3 \cdot C}}$$

$$H = 708 \cdot C t_0\left(1 - \epsilon^{-\frac{30}{3 \cdot C}}\right)$$

These formulæ have been arrived at without taking into account the fact that the gases grow denser and travel slower as they grow colder, and that they therefore remain longer in contact with the tube surfaces. Fortunately the influence of the reduction of speed and increased density balance each other, and no correction need be added to the above.

Before leaving the subject of conductivity, it will be as well to mention the case of tubes which are partly choked with ashes. One would suppose that their efficiency is reduced in the same ratio as the exposed surface, but this is not quite the case, especially if they are coated with scale, and if the differences of temperature are not too great. Then the heat travels down the sides of the tubes, and the exposed inner surfaces, being colder than those of tubes without obstruction, would also absorb more heat per square foot of exposed surface. The numerical values can be obtained by determining the values of the various constants in the following formulæ —

$$t_1 = A + B \sin \alpha \cdot x$$

$$t_2 = a\left(\epsilon^{\beta x} + \epsilon^{-\beta x}\right)$$

Here t_1 is the temperature of the top part of the tube, and t_2 that of the bottom part; x is measured on the circumference of the tube, starting from the top or bottom. All the other values are constants, which can be determined: t_1 and t_2, as well as their first differential quotients, must be equal at the boundary formed by the ashes.

As there exist very large differences of temperature in a boiler, it is desirable, while dealing with the flow of the gases, to take them into account, and it will therefore be necessary to construct the formulæ for the resistance of gas in motion. Starting from the well-known formula

$$v^2 = 2\,g\,h$$

where v is velocity of acceleration due to gravity, and h the height of the fall or the height of the liquid, it can be replaced by $\frac{p_1}{S}$ which is the pressure per square foot divided by the weight of one cubic foot of gas. S the denominator is inversely proportionate to its absolute temperature T_1, and we have

$$v^2 = 2\,g\,\frac{p_1}{S_0}\,\frac{T_1}{T_0}$$

$S_0 = 0{\cdot}0845$lb. per cubic foot at 32° F. or at $T_0 = 493°$ absolute temperature. Let a be the sectional area of one tube, then the weight which passes through it per hour is

$$Q = \tfrac{2}{3}\,v \,.\, a \,.\, S \,.\, 3600 = \tfrac{2}{3}\,a \,.\, 3600\sqrt{2\,g\,p_1\,S_0\,\frac{T_0}{T_1}}$$

Here the coefficient $\frac{2}{3}$ is a coefficient of experience. Seeing that the resistance to entering the tube is inversely proportionate to the absolute temperature, it is more than probable that the surface friction in the tube is also dependent on it.

$$p = p_1 + p_2 = \frac{Q^2\left(\frac{9}{4}T_1 + 0{\cdot}012\,\frac{S}{a}\,T_2\right)}{(3600)^2\,a^2\,2\,.\,g\,S_0\,T_0}$$

Here S is the surface of the tube, T_2 is the average temperature of the gas in the tube, and 0·012 is a coefficient of friction adopted by Rankine. Let T be the absolute temperature of the water in the boiler, then the final temperature is

$$T + t = T + t_0\,\epsilon^{-\frac{10 \cdot S}{h}}$$

and the average temperature is

$$T_2 = T + t_0\,\frac{h}{10\,S}\left(1 - \epsilon^{-\frac{10 \cdot S}{h}}\right)$$

Inserting the previously found notation, and replacing $\frac{Q}{30}$ by C, we have

$$T_2 = T + t_0\,\frac{20}{3\,C}\left(1 - \epsilon^{-\frac{20}{3C}}\right)$$

None of these values are negligeable, for C can easily be made to exceed unity. The pressure p can then be expressed by a formula of the following form:—

$$p = C^2\,(a\,T + b\,t_0) + C\,c\,.\,t_0\left(1 - \epsilon^{-\frac{20}{3\,.\,C}}\right)$$

Here a b c are constants, and it will be seen that the resistance encountered by a gas which passes through a boiler tube depends not only on the absolute temperature in the combustion chamber ($T + t_0$), but also on C^2 and C^2.

As matters would get too complicated if the formulæ were carried further, I shall insert the following numerical values, which would, of course, have to be altered for different cases:—Let the temperature of the boiler water be 379° Fahr. Then $T = 379° + 461° = 840°$. Let the absolute temperature in the combustion chamber be 2840°; then $t_0 = 2000°$, and if the boiler tubes are 3in. diameter and 6ft. long, we have $a = 7{\cdot}07$ square inches = 0·049 square feet. S, the tube surface, = 4·71 square feet.

$$p = C^2\,0{\cdot}173 + C\,.\,0{\cdot}166\left(1 - 2{\cdot}718\ldots^{-\frac{20}{3\,.\,C}}\right)$$

$$\log 2{\cdot}718\ldots^{-\frac{20}{3\,.\,C}} = \frac{1{\cdot}815\ldots}{C}$$

$$\log t = 3{\cdot}301 - \frac{1{\cdot}815\ldots}{C}$$

All that is now necessary is to determine the value of p, which is the difference of pressure at either end of a tube. Let P be the value of p for the lowest row of tubes in a combustion chamber; then for any row of tubes situated n feet higher we have $p = P + n\,\Delta p$. Here Δp is the difference of weight of 1 cubic foot of gas in the combustion chamber and in the smoke-box. The temperature of the first of these is assumed to be 2840° absolute, and the latter can safely be taken as the mean value of all the tubes, it is $840 + t$. Now, as the weight of 1 cubic foot of gas at 32° Fahr. is 0·0845lb., we have—

$$\Delta p = \left(\frac{493}{840 + t} - \frac{493}{2840}\right) 0{\cdot}0845$$

Suppose now that the combustion chamber with which we are dealing consists of 10 rows of 10 tubes pitched 4in. apart: then $n = 2\frac{1}{2}$ft., and $C_1 = 100\,C$ is the total weight of coal burnt per hour for supplying these 100 tubes, then, assuming C_1 to be 100, 200, 400, and 800 lbs. per hour, corresponding to easy firing, ordinary firing, and strong firing, with natural draught, and, lastly, strong forced draught:—

C_1 Consumption per hour. Lb.	$379° + t$ Temperature in smoke-box. Deg. Fahr.	p Average resistance in tubes. Lb per sq. ft.	$\frac{\Delta p}{\Delta C_1}$	Δp Difference of weights of gas. Lb per ft.
100	382	0·33!0	0·0049	0·035
200	626	0·983	0·0079	0·024
400	1,094	3·20	0·0150	0·012
800	1,564	11·60	0·0170	0·006

In order to find the relative quantities of gas which pass through the top and bottom rows of tubes, multiply the values in the fifth column by 1½ft., being half the height of the combustion chamber and divide by the values in the fourth column, and add and subtract from the values of C_1, and divide the one by the other thus:—

$$100 \pm \frac{1{\cdot}25 \times 0{\cdot}035}{0{\cdot}0049} = 100 \pm 9 = 109 \text{ and } 91,$$

Showing that the top rows receive $\frac{109}{91}$, or 20 per cent. more than the bottom rows, when the average consumption is 100lb. per hour. In the other three cases this value is 4 per cent., ½ per cent., and ¼ per cent. The difference of the temperature in the smoke box for each extra pound of coal burnt is 0·2° when the consumption is only 100lb., therefore with 20lb. difference the range of the temperature of the waste gases is only about 4°. In the three other cases the difference for each extra pound of coal is 0·3°, 0·6°, and 1·0°, and the difference of the final temperatures from the lowest and highest tubes are 2·4°, 1·2°, and 1°, showing that generally the heat is pretty evenly distributed amongst the tubes. I have taken no account of the actual efficiency of the boiler surface, but have restricted myself simply to the theoretical question of the distribution, and by applying the above results to those trials of marine boilers which I am glad to see are now often carried out, it will be possible to obtain accurate values as to the various heating surfaces.

*Ann. du Génie Civil, 1874.

Mr. McFarlane Gray said the question opened up was one which was very little understood. The question of the condition of the tubes and the formation of scale was of the greatest importance to the rate of combustion, and deserved full consideration.

Mr. Fothergill said that if the paper was, as he took it to be, a theoretical one, we must put on one side the question of scale and the condition of the tubes. From the title one would have expected that the efficiency of evaporation would have included the various parts of the heating surface of the boiler generally, whereas the tubes had been particularly dealt with. The heat of the tubes must depend upon the completeness of combustion in them. A comparison had been made between a locomotive and a marine boiler, but he failed to observe the similarity. In the locomotive they got the more complete state of combustion for the time being, and they had no deposit in the tubes; therefore the heat would be much greater than in a marine boiler. He did not think more of the gases passed through the upper than through the lower tubes. In the marine boiler it was known that the lower tubes became choked first, and this could not be so if less passed through them. Again all practical engineers were fully aware that tubes might have a considerable deposit on the top, and be bare at the bottom. He quite agreed that it was greatly to the advantage of economy to bottle up the gases in the tubes, and he thought mechanical draught then became useful. The temperatures given in the last table should depend on the conditions of combustion.

Mr. Stromeyer, in reply, considered that the thickness of the plates did not make much difference. He had found the chief resistance of the gases to be when they passed into the tubes. There was no difference in the thickness of the scale in the top and bottom rows of tubes, nor between the top and bottom of each separate tube as had been suggested. He thought it was a mistake to suppose that the gases could be retarded, while at the same time they were being forced through the boiler mechanically. He had proposed draught retarders, not on account of the extra resistance which they offered to the products of combustion, but for the disturbing influence set up.

The next paper read was by Mr. Andrew Betts Brown, F.R.S.E., on "The Application of a System of Combined Steam and Hydraulic Machinery to the Loading, Discharging, and Steering of Steamships."

Since addressing this Institution, in 1884, on the subject of a complete system of direct acting hydraulic machinery for first-class passenger steamers, the author has effected many improvements, which have been suggested by the varied types of over fifty steamships fitted.

The sympathy of the stevedores, who have to work out cargo in the shortest possible time, are only with those who make their particular interest the paramount one in the general compromise which obtains on board ship. When at sea, captains and other officers are equally anxious to perfect their departments, and the apparatus described in this paper are the outcome of the various complaints made by these difficult-to-please gentlemen; by this term no offence is meant, but rather a compliment, as without such fault-finding, duly considered, it would not be possible to make any advances.

The Hydraulic Derrick.—The derrick is shown in vertical elevation in Fig. 1, and in plan in Fig. 2 (page 340). A is the lifting cylinder, with its ram and pulleys placed between the girders of the derrick. On the right-hand side is placed the slueing cylinder B, with its ram pulleys and rope tackle made fast at C, the derrick being pulled in and falling out by gravity. On the left-hand side is the topping cylinder D, which with its ram pulleys and tackle in duplicate, lowers the derrick over the side of the ship, as the hatch is too close to the mast to admit of the cargo being delivered over the side without such appliance. Water is admitted to these cylinders through stuffing boxes at E, which are controlled by the three valves and levers, situated close to the hatch at F. All the motions are independent, and can be worked simultaneously. The derrick is stowed horizontally when at sea, and its lifting cylinder suffices to raise and lower the derrick.

The Steam Derrick.—In cheap cargo ships, and those carrying few passengers, the large percentage of cost which the hydraulic system bears to the total cost of the ship is principally brought about by the expense of the compound surface condensing pumping engines and steam accumulator. The advent of high-pressure steam, however, has enabled the author to preserve the form of the general deck discharging gear, so far as speed of working, noiselessness, and durability are concerned, but to use steam as the motive force in place of water, and so dispense with the pumping engines, as well as the space occupied in the engine

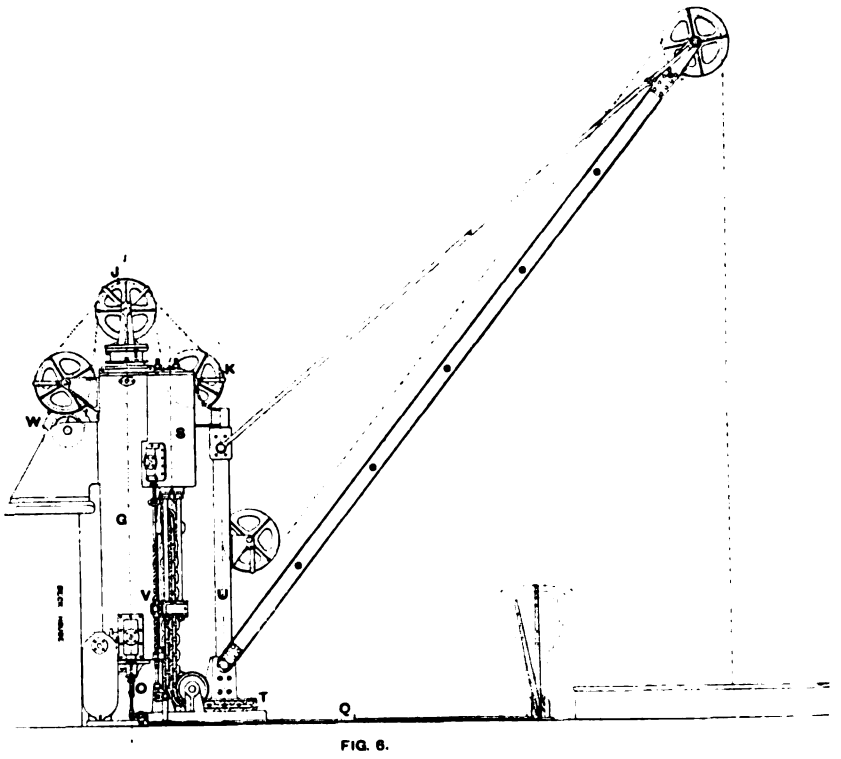

FIG. 6.

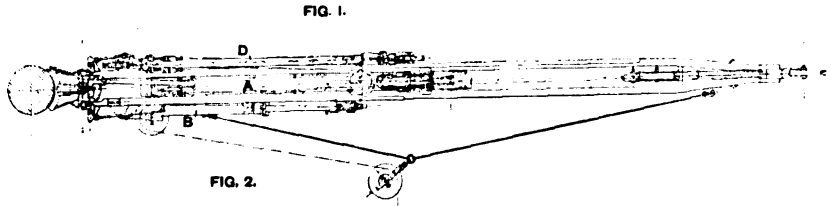

FIG. 2.

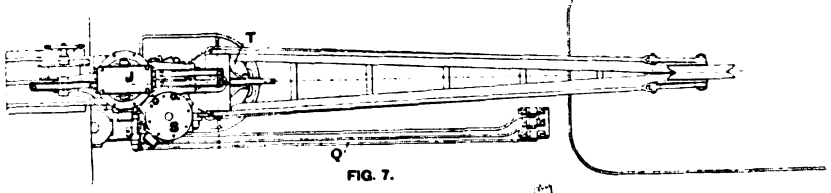

FIG. 7.

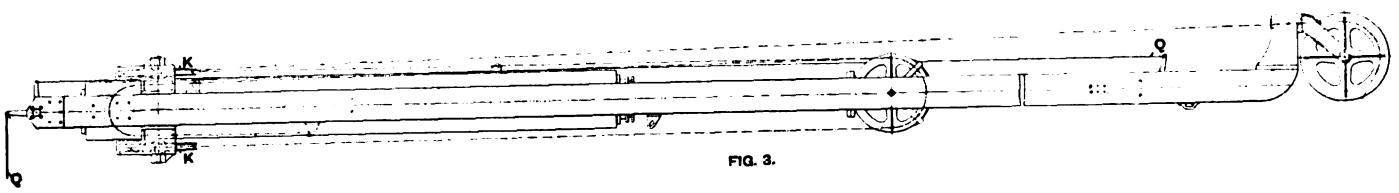

FIG. 3.

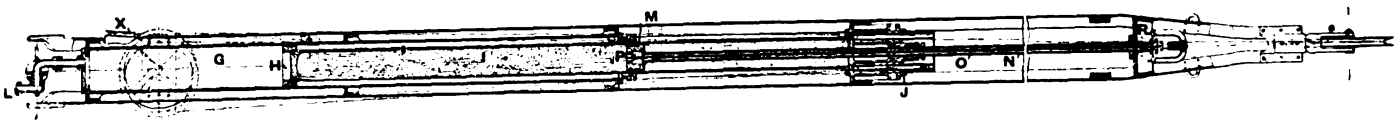

FIG. 4.

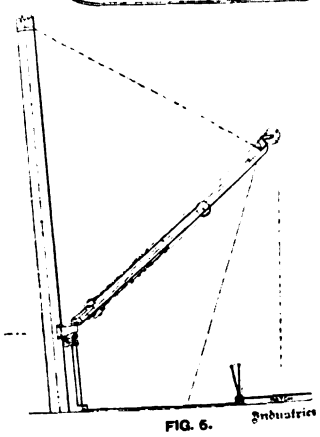

FIG. 5.

rom. Although this derrick cannot compete with hydraulic machinery, yet its action is precisely similar, and the high-pressure steam (150lb. to 180lb.) enables the work of lifting to be done by a steam cylinder of comparatively small diameter. In fact, the derrick is lighter than a hydraulic derrick, having slewing and topping gear, which motions, however, cannot be conveniently fitted to the steam derrick. It is therefore advisable to hang these derricks with the points of support plumb, and they will then swing quite easily by hand with the usual tackles. Fig. 3 shows a side view, and Fig. 4 a section, while Fig. 5 shows the derrick in position, with the valve handles close to the hatch. A steam cylinder G is fitted between two channel beams; in it works a piston H, whose ram T carries at its extremity a crosshead J and two grooved lifting pulleys; a wire rope passes round these pulleys and round the fixed pulleys K. When steam is admitted under the piston H from the pipe L the load is raised. It is necessary, however, to control the movement of this piston, so that an inelastic fluid should be interposed in the operation of heaving and lowering, otherwise the piston and its ram might move like a shot out of a steam gun. To effect this the trunk I is bored out and fitted at its upper end with a stationary piston M, which is carried by a tube N. A rod O passes through a stuffing-box in this tube for the purpose of opening a clack-valve P in the stationary hydraulic piston; this valve is only allowed sufficient lift for the maximum lifting speed of the derrick, which may be 5ft. to 10ft. per second. The whole of the interior of this trunk is filled with water, as shown in dotted lines. In making a lift it will be seen that all the water has to pass to the upper portion of the stationary control piston, and, as the valve falls into its seat and the steam is exhausted, the load will be held until this valve is opened by pulling the rod Q on end, lifting the valve L out of its seat. The rod is actuated by a separate lowering lever shown in Fig 5. The trunk is kept filled with condensed water under boiler pressure by being connected to a reservoir which has a sufficient quantity of condensed water from the branch R, so that it will always remain full, and will compensate for the displacement of the tube N. The annular space is connected with the exhaust steam pipes by trunnions. The lifting rope may be varied in length by being attached to various points on the side of the derrick, either direct or by passing round the segment X, so as to economise steam when lifting through short heights. It is claimed for this derrick that it is simple, rapid and noiseless, and being hung entirely on the mast, it occupies no deck space, and is suitable for the cheaper class of cargo and passenger ships.

Where masts are not available a form of crane shown in Figs. 6, 7, and 8 is convenient. This is supported by being bolted to the deck at the lower part of the lifting cylinder, the upper part being attached to the deck-house. Fig. 8 shows the lifting cylinder with the hydraulic controlling ram in section. The only difference is that the tube N carrying the stationary piston passes down through the cylinder end instead of up, as in the derrick. When the crane is slued a double-acting steam cylinder S operates on an endless chain, which passes round a pitched wheel T. The swinging valve is controlled by an automatic cut-off gear V, so that the jib will stop at any point assigned to it by the travel of the swing handle in its quadrant. Where a deck-house is not available, this crane can be arranged on the usual post which passes to the lower deck; in this case an all-round swing can be obtained. The length of the lifting rope may be varied according to the height of lift required by the winding drum W, which carries the fast end of the rope, so that the steam piston may be kept, as far as possible, working at the lower end of the cylinder, otherwise steam would be unnecessarily wasted.

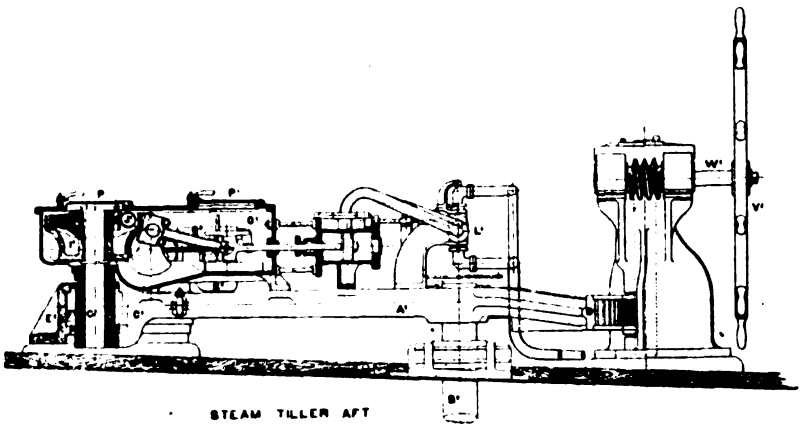
STEAM TILLER.—The next important subject is the question of steering gear, which, from the various reports of captains, appears to formulate itself into the following requirements of an ideally successful steering gear, whether it be actuated by water or steam: (1) The steering engine or machine should be attached to the rudder head without the intervention of chains or ropes; (2) it should let go the rudder when unduly strained, and when the abnormal strain has gone must return to its former position; (3) an easy method should be provided of connecting from steam to hand gear, which shall not involve the engagement of a clutch, or the more common practice of shipping large bolts into a fixed crosshead from a loose one, all of which appliances take much valuable time to get into their places, particularly when a ship is

Digitized by Google

rolling at sea, with the rudder adrift; (4) the communication to the bridge from the machinery aft should be of a kind which dispenses with rods, chains, and shafting, all being equally troublesome to the shipbuilder to arrange, and to the officers attending to them to keep in order, involving oiling bearings, pulleys, and tightening up ropes and chains.

To meet this want the author has designed what is termed a steam tiller and telemotor. Fig. 9 shows an elevation of the steam tiller with the hand steering gear, Fig. 10 being the plan. Fig. 11 shows the telemotor in vertical section. Fig. 12 is the same in plan. Fig. 13 is the corresponding cylinder aft. In Fig. 1 A^1 is a cast-steel tiller keyed on to the rudder head B^1, which has at its after end a double jaw C^1 fitted with bearings. At the other end D^1 there is a toothed segment, into which a pinion works. Aft of the tiller there is bolted to the deck a toothed quadrant E^1, into which the steel pinion F^1 gears. The shaft G^1 is shrunk into this, and, passing through the bearings on the jaws of the tiller, terminates in an expanding clutch wheel H^1. The worm wheel I^1 embraces this clutch wheel, there being a strip of elm wood interposed circumferentially between the two. This wood possesses the property of having a coefficient of friction nearly constant, whether it is wet or dry. The necessary friction to drive the shaft G^1 is obtained by the worm and worm wheel arrangement J^1, which expands the clutch wheel against the laminated spring K^1. The steering engines are carried on the tiller and move round with it, receiving and exhausting their steam through a double stuffing box arrangement L^1 mounted on the axis of the rudder head. The steam cylinders M^1 are of the usual well-known construction, originally introduced by Mr. Macfarlane Gray. The reversal is effected by changing the direction of the steam, which enters the cylinders through the slide valve N^1. The whole of the valve gear—viz., slipper guides, connecting rods, crank shaft, and eccentric rods, are enclosed in a water-tight box or chest O^1, having two hinged lids P^1, for occasional examination. For the purpose of oiling the various parts a tank Q^1 is fitted between the engines, from which proceed pipes leading to every bearing and joint, piston rods, valve rods, worm and wormwheel. Two valueless oil pumps R^1 R^1 are worked from the eccentric rods, and they keep up a continual supply of oil, which returns into the well S^1; the large end of the connecting rods dips into a trough and throws the oil generally about the clutch and wormwheels; a regulated quantity of oil finds its way down the shaft G^1 to the main bearings on the end of the tiller. From this arrangement it will be seen that it is only necessary to pour a few gallons of oil into the machinery casing, and the oiling of the various parts will be effected automatically by the working of the steering gear. The steering lever operating on the valve is shown at S^1; it is actuated by a hand-wheel T with worm and worm sector U^1 with its shaft and corresponding lever. This opens the slide valve N^1 in either direction, and the revolving motion of the tiller and engines shuts it again. The hand-steering wheel is shown at V^1; it is mounted on a worm shaft W^1, which gears into a wormwheel precisely similar to that of the steering engine at I^1. A vertical shaft passes down into a steel pinion, which gears with the toothed segment D^1. This shaft is brought into gear with the wormwheel by an expanding clutch similar to that on the engine shaft, and lettered similarly H^1.

In proportioning the strain of the engine with the torsional strain on the rudder head it is not necessary to consider the question of a safe strain; in fact, the engines may be made overpowerful, so as to allow for reduced boiler pressure. In practice the clutch H^1 is expanded at full speed trials sufficiently tight to put the helm hard over, but no more, and the worm wheel screw then set, so that in changing from hand to steam it cannot be made dangerously tight. It will be seen from this arrangement that any abnormal strain on any part of the gear or rudder head, caused by heavy seas, must be transmitted through the elm wood liner; this is held tight by the spring K^1, which has not sufficient hold to break any part of the machinery, but slips, and the valve gear opening brings the rudder into its original position. This friction clutch arrangement being also on the hand steering gear, admits of connection at any position of the rudder, even when flying about adrift; also the change from steam to hand, or *vice versâ*, is effected without shipping bolts or jaw clutches, so difficult to manipulate in emergency. It is therefore submitted that this gear fulfils the foregoing conditions, 1, 2, and 3.



TELEMOTOR.—The object of this device is to communicate the motion of a revolving wheel at the bridge to the rectilinear motion of a piston and its connecting rod attached to the steering lever, acting upon a steering valve, which may be either steam or hydraulic. Fig. 11 shows a vertical section of what is really a hand-pump The steering wheel A^2 drives a shaft and pair of bevel wheels B^2, which actuate a vertical shaft C^2; the pinions D^2, one of which forms a nut, act on the screwed piston rod E^2. This is shown at mid-gear, the piston F^2 being in a cylindrical distance piece forming part of the upper cylinder G^2 and the lower cylinder H^2; this distance piece, however, allows a free passage of water through an annular port from the cylinder G^2 to the cylinder H^2, as it is open at the top and bottom of these cylinders one-sixteenth of an inch. On turning the wheel A^2 the piston F^2 will travel one-sixteenth of an inch each way before the cylinders G^2 or H^2 become effective hand-pumps. The machinery on Fig. 13 consists of an ordinary double-acting hydraulic cylinder I^1 fitted to the piston J^1 and its rod, which is connected to a crosshead K^1, and from there to the lever S^1 in the steering gear. The after steering wheel T^1 being disengaged, two spiral springs L^1 L^1 tend to force the piston J^1 into mid-stroke, and consequently bring the rudder amidships; they have not only sufficient power to overcome the friction of the gear aft, but tend to make the wheel amidships run back to mid-stroke. The cylinder G^2 on the bridge (Fig. 11) is connected by a pipe, ¼in. in diameter, to the corresponding letter G^2 on the cylinder aft, while the cylinder H^2 is connected to the corresponding letter H^2 aft. It will be seen that (the pipes and cylinders being full of water) the piston F passes the distance piece, say, on the upper stroke; the piston J^2 aft will move towards the cylinder end, thus increasing the initial compression of the springs L^1 L^1. Let us assume that we put the helm hard over in that direction and leave it there for an hour, and we find that a slight leakage in the piston has allowed the gear aft, by virtue of the springs, to come amidships, while the bridge wheel indicates hard over; the order is now given to reverse the helm—that is, to cause the piston F^2 to leave the cylinder G and to enter the cylinder H^2. The gear being out of correspondence, it sends the water into that half of the cylinder aft lettered H^2, driving the piston J^2 hard over towards the stuffing-box end of the cylinder; but whenever the piston F^2 enters the distance piece, there is established a free communication between the cylinders on the bridge and both ends of the cylinder I. The springs then exert their force and run the gear amidships, and the whole is again in correspondence. An extreme case has been taken of an hour's time hard over with a leaky piston; but as in practice the helm is put very frequently to port or starboard, and the combination of the piston F^2 passing through the cylindrical distant piece M^2 with the springs aft, tending to put the steering gear amidships, causes a continual rectification of the relative positions of the bridge wheel and the cylinder aft, which may be disturbed by a worn-out leather. Under exceptional circumstances it may happen that when carrying weather helm for a long period of time, the piston F^2 may be working entirely in the cylinder G^2 or the cylinder H^2, and having no opportunity of passing the distance piece M^2, and consequently with a defective piston there would be no automatic regulation. For that purpose a foot lever N^2 is provided, which opens a cock O^2, and thus enables the steersman to run his wheel back and bring the indicator over to zero, when the steering is then effected with the piston working in or about the distance piece, and the automatic regulation will go on. Any external leakage is made up by water stored in a small tank P^2, which enters the end of the cylinders by inlet valves in the boxes Q^2 Q^2, in which are also placed safety valves to allow for the expansion of the water in the pipes through change of temperature. One of these boxes is shown in section to a large scale at Fig. 14. It is scarcely necessary to say that with well fitted and good leathers no regulation takes place, but it is necessary to provide some such device, the tendency of which is to go *into order* rather than, as is usual, *out of order* as wear takes place.

In the discussion which followed,

Dr. Kirk wished to know whether, in the comparative tests between the steam winch and derrick, the winch was an old one.

Industries

Mr. Seaton thought it a matter of regret that some such arrangement was not fitted on board ships, especially in substitution for cranes. Cranes were really more troublesome than winches. So far as the clutch arrangement was concerned, he knew it would answer very well, because on some machines he had made recently they had some such arrangement which answered well, and was perfectly noiseless and efficient. It was no doubt an advantage to be able to disconnect readily the hand and steam steering gear. Many ships had been lost through the pins having to be taken out when an accident happened.

Mr. McFarlane Gray said Mr. Brown had attributed to him the introduction of steam steering. What he did introduce was not the system, but the controlling valves.

Mr. White wanted to know why the rams were carried on the jib itself. He said that the steering gear was receiving the consideration of the Admiralty.

Mr. Brown, in replying, said the steam winch with which the tests were made was one which had been used and put in perfect order, as a new winch would have had considerable friction, both in engines and gearing. The cylinders are placed in the jib of the derrick because room could not be found for them elsewhere, either on the deck or on the mast. The steering gear has been especially devised for the merchant service, but there are no obstacles to its being adapted also to naval requirements.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 8th April, 1890.

Iron.—The influence of the holidays, apart from the general aspect of the iron market, remains unchanged. The tendency of business is to shrink, and the downward course of prices shows that this tendency is something more than a passing influence. Here in Paris business is languid. To tempt buyers the merchants are offering bars at 156s. and even 152s., and joists at 4s. above these prices. It is a significant fact that the lower figures are for future delivery. In the Haute-Marne the market continues animated, the demand for wire and wire nails being very brisk; but in the other centres of the iron trade the demand is falling off, and prices are maintained with difficulty.

Metals.—Copper is firmer, the feature of the market being a rise in "best selected." This is, however, a mere fluctuation, due to speculative operations. There are no solid grounds even for the maintenance of the present rates. Best Chili bars are quoted £52, and best selected £58. Tin is still quoted £100 for Banca, but the market is weak. Lead is quiet at £13, delivered at Havre. Spelter continues its downward course, Silesian being now quoted £23 12s. at Havre.

Labour.—Though French industry is not yet seriously troubled by the labour movement in progress abroad, it cannot be said that it is not seriously threatened. There is considerable ferment among the working men of all classes, and the organisations and preparations which are being made for the "manifestions" on the 1st of May show that this country is not likely to be long exempted from the labour disturbances that are obstructing the course of trade in neighbouring countries. The Socialist leaders are hard at work sowing discord everywhere.

The Northern Canal.—The scheme for the construction of the great northern canal, the waterway that is to connect the capital with the mining and manufacturing district of the North, is again being vigorously promoted. The return of M. Freycinet to power renders it probable that the project will be carried through on this occasion. It is one of immense importance to French industry, and not without interest to the import trade in English produce, particularly coal.

BERLIN, 7th April, 1890.

Iron.—Business in iron was very brisk in the early part of last week in anticipation of the Easter holidays. For the moment there is nothing doing, and there will be a slack market for several days to come. The customs returns for the first two months of the year show a threefold increase in the imports relatively to 1889, the total quantities being 87,776 tons against 29,174 tons. The pig iron and scrap received from abroad amounted to 75,667 tons against 21,714 tons in the corresponding period of 1889. Bars show an increase from 2,643 tons to 4,399 tons, about the half of which come from Great Britain.

German Iron Abroad.—The total exports of German iron in the month of February amounted to 79,294 tons, against 64,334 tons in January and 91,804 tons in the same month of last year. The effect of high prices in restricting the export trade becomes more distinctly visible every month. The following is a classified account of the trade in the first two months of the current year compared with that of the corresponding period of 1889: Pig iron, 18,510 (35,153) tons; old and scrap iron, 4,080 (4,046) tons; half-wrought iron and steel, 2,692 (4,192) tons; finished iron and steel (bars, angles, and plates), 30,846 (44,899) tons; wire, 17,763 (30,086) tons; wire nails, 5,509 (7,813) tons; rails, 20,124 (15,925) tons; other railway iron, 8,075 (7,625 tons; heavy castings, except ordnance, 4,220 (2,224) tons; other manufactured goods, except machinery, 31 809 (30,173) tons. Total, 143,628 (182,036) tons. The falling off, it will be seen, is chiefly in crude iron, finished iron and steel, and in wire. The shrinkage in the latter is very serious. Wire nails, too, have fallen off heavily. The quantity of wire nails shipped to Great Britain in the two months was 1,923 tons. The consignments of wire nails to Japan amounted to 1,237 tons.

Labour.—The labour question continues to develop itself. From all parts of the country we learn that fresh demands are being made by the working men of all the principal industries. The miners of the Chemnitz district are asking for a 20 per cent. advance in wages and the eight hours' shift. The colliers of Upper Silesia are discussing a similar project. There is much commotion in all trades, and everywhere there seems to be a determination to strike for higher wages and shorter hours. The movement is of immense importance to German industry.

Ozokerite Mines.—The scheme of the group of speculators known as the "Rothschild Ring," to buy up, in conjunction with Bleichröder, the ozokerite mines in the district of Boryslau, and to reunite them in one great share company, has proved abortive. But the *Compagnie commerciale française* have bought, in conjunction with a Vienna merchant at Boryslau, a number of these mines, for the purpose of working them in a more rational manner from two properly arranged engine shafts. These changes will lead to a considerable reduction in the cost of production of ozokerite.

Lignite on the Baltic Sea.—A discovery of a bed of lignite has lately been made on the shores of the Baltic Sea, near Palmnecken and Lettausdorf. The Breslau Mining Office have made several borings, and have proved that the seams are thick and likely to prove remunerative.

Chemicals.—The directors of the firm of Meister Lucius & Brüning, of Höchst-am-Main, whose specialty is the manufacture of Dr. Knorr's antipyrine (Lion brand), have decided to propose at the general meeting the distribution of a dividend of 22 per cent. for 1889, as compared with 16 per cent. in 1880.

The Water Communications of Berlin.—The great importance of the several waterways for Berlin traffic may be seen from the fact that no less than two-fifths of the entire imports from Berlin came by water, whilst the ten railways have the other three-fifths between them. The number of boats on the waterways here has declined from 96,151 in 1888 to 92,930 in 1889, but the total weight of the goods arriving has risen. The goods passing through Berlin by water amounted to 283,667 tons, the arrivals to 4,351,550 tons, and the departures to 327,538 tons.

The South-German Telephones.—The Frankfort Chamber of Commerce has addressed a petition to the postal authorities in favour of erecting a telephone network to connect the leading business places of South Germany. The towns proposed to be included in the network are—Frankfort-on-the-Main, Cassel, Giessen, Worms, Schweinfurt, Mannheim, Aschaffenburg, Würzburg, Bamburg, Nuremberg, Augsburg, Munich, Pforzheim, Stuttgart, Coblenz, and Kreuznach.

Underground Telegraphs.—The laying of underground telegraph wires is to be begun in Bavaria. A Bill on the subject will be laid before the present Bavarian Diet. The main lines may be from Munich to Ingolstadt, Nuremberg to Bayreuth, or Munich to Landshut, and Regensburg and Bayreuth to the Saxon frontier near Hof, to be connected with the existing imperial line from Berlin to Dresden. To establish a direct underground connection between Munich, Hof, Dresden, and Berlin, representing a distance of 850 kilometres, the Imperial Post Office will also have to lay down a wire of 216 kilometres in length between Hof and Dresden. Since 1877, 5669 kilometres of underground wires have been laid in Germany, with 38,000 kilometres of wires. All important commercial towns and seaports, and every fortress and naval port, are now connected with Berlin in this secure way.

VIENNA, 7th April, 1890.

The Coal Market.—The coal traffic continues to be very animated, and there has been a brisk demand, especially for the export. Westphalian manufactories have petitioned the Bavarian and Bohemian railways to reduce the tariffs for coal transport, in order that they may be able to procure coals from Bohemia. The Aussig-Teplitz Railway Company is enlarging its capital, in order to buy new rolling stock for the coal transport. The yearly report of this company shows an animated export to South Germany. The colliery "Victoria-Tiefbau of Brux" produced during last business year the total quantity of 369,728 tons of brown coals, and had a clear profit of 137,000 florins. It pays a dividend of 6 per cent. The "Westböhmischer Bergbau-Actienverein," which has large possessions in Western Bohemia, held its general meeting last week. According to the report, the income of this association during last year amounted to 1,328,000 florins. In its works there have been produced 337,000 tons of coal. A dividend of 5½ per cent. was paid. Coke has a good sale, and great quantities are going to Germany.

The Iron Market.—Nothing new can be said of the iron market; the transactions are very animated, and the tendency remains firm. It would be very advantageous if the pig-iron works should soon complete the old orders, because there are a number of new ones of some importance. There is an animated demand for all sorts of building iron; indeed, the building season shows an extraordinary animation. There is a good demand for sheets, both black and tinned, and agricultural machines have a good sale. Rails are in the best request.

The Austrian Coal Trade in 1889.—The principal exports were brown coals, and the principal import ordinary coals. The import of black coal amounted last year to 3,272,627 tons, against 3,085,321 in 1888; 682,385 tons of the same sort have been exported; in 1888 the quantity was 691,196. The total export of brown coals in 1889 was 5,270,707 tons, and the import 9,112 tons. The import of coke amounted to 192,345 tons, and 39,660 tons have been exported.

BRUSSELS, 8th April, 1890.

The Coal Market.—In spite of the efforts which are being made continually by the consumers, the prices of coal and other forms of fuel keep very firm and no concessions can be obtained. In all the coal centres the stocks are being rapidly reduced, and at most of the pits there is hardly any reserve. It is no wonder, therefore, that the coal-owners can demand their own prices. At Liége, nuts for rolling mills cannot be bought at less than 18fr., and 19·50fr. is demanded for the best qualities; while at Charleroi the price of this sort is 18fr. At one of the collieries in the South nuts have been sold largely at 20fr. The prices in the Mons district are similar to the above, if anything, rather higher. Small sorts for coking purposes are unvaried at Charleroi and in the Centre, 19·50fr. being the price for deliveries over the next three months. The producers of coke met at Brussels last week and decided to maintain the price of 35fr. firmly. During the past week the carriage of fuel over the State railways amounted to 24,136 waggon-loads, as compared with 22,176 waggon-loads during the same period of 1889.

The Iron Trade.—The iron market is quiet. New orders come with difficulty, and there is a great deal of reserve shown by the buyers. However, all appearances point to a continuance of the high prices, for there is no sign of yielding in the cost of raw materials. The contract for 2,000 tons of Goliath rails for the State railways has been divided between the Angleur, Ougrée, & Cockerill Companies, at a price of 177·5fr. per 1,000 kilogs. The ironmasters met on Sunday last and decided on the restriction of their production.

The Glass Trade.—The demand is beginning to improve somewhat, especially from England and the United States. Some satisfactory repeat orders have been received from Canada. The production generally has been increased. A new furnace is to be started at the works of Les Verreries Morel at Lodelinsart, making the 296th in use in Belgium. In view of the continued high prices of fuel there is a movement among some of the glass manufacturers in favour of establishing a syndicate for the buying of raw material.

DÜSSELDORF, 8th April, 1890.

The Foreign Coal Trade.—Great activity prevails in the foreign coal trade. The imports are exceptionally heavy, a circumstance due partly to the larger requirements of the manufacturing industries and partly to the interruption of the output of the German mines by strikes. The quantities imported in the first two months of the current year were as follows, the figures in parentheses being those of the corresponding period of 1889:—Lignite, 900,615 (641,673) tons; coal, 501,522 (497,092) tons; coke, 78,200 (42,517) tons; briquettes, 10,315 (4,037) tons. About two-thirds of the coal received came from England. The exports, which show a shrinkage in coke and briquettes, were for the period in question as follows:—Lignite, 1,909 (1,560) tons; coal, 1,518,831 (1,432,175) tons; coke, 135,269 (143,168) tons; briquettes, 16,196 (17,533) tons. The quantity of coal sent into Holland amounted to 459,504 tons, and that of coke to 12,428 tons. A good deal of ground has been lost in Holland of late, the high prices rendering it impossible to hold either market against English competition.

Iron.—The Easter holidays have for the time put a stop to the business of the iron market. But there was no life in the trade in the half week preceding Good Friday. The demand for pig iron was very slack, and merchants' prices dropped a little for some classes. Thus Rhenish-Westphalian forge was offered at 90s., Siegen forge at 89s., and foundry pig at 96s. Manufacturers refuse to make any concessions. The market for finished produce was fairly active for joists; but generally the demand was weak. Some revival is expected after Easter, the present lull being in large part due to the uncertainty of the labour situation. This expectation is founded on the belief that the labour difficulties are likely to be overcome within a short time. Probably a disappointment lies in this direction. The demand for hoops is likely to increase in the course of the next month. Founders have plenty of work in hand.

The Cement Industry.—The cement manufacturing industry is in a flourishing state. At a general meeting of the Westphalian Cement Manufacturing Company, held here the other day, a dividend of 19 per cent. for the year 1889 was declared. Judging from the trade of the first quarter, the current year will compare favourably with the last. The export trade is very brisk. The quantity of cement exported in the first two months of 1890 amounted to 35,216 tons, against 16,815 tons in the corresponding period of 1889.

LILLE, 8th April, 1890.

Iron.—The state of the iron market in this district is, notwithstanding reports to the contrary, unsatisfactory. Consumers not only abstain from buying, but, in some instances, those who have considerable stocks in hand are selling in the belief that they will be able to replace them at lower prices before the end of the second quarter of the year. The commonly held opinion is that the present level of prices cannot be much longer maintained. The tone of affairs is, therefore, weak and hesitating. The only encouraging feature in the prospect is a downward tendency in the prices of coal.

Textile Manufactures.—The business in textile goods has been interrupted by the Easter holidays, but irrespective of this influence it is easy to discern a declining tendency in the trade in linen woven goods. As usual at this season the demand is steadily falling off. The trade of the year hitherto, however, has been very satisfactory considered relatively to that of 1889. The woollen goods trade of Roubaix is featureless; but the market for raw wool, which has been declining for some time past, has suddenly revived. Prices are now firm with an upward tendency. For the present manufacturers are buying but sparingly.

Flax and Yarns.—The market for flax and yarns was, down to the time of its interruption by the Easter holi-

Digitized by Google

days, exceedingly active for home-grown produce, and prices were very firm. The demand for Russian goods also showed more life. Tows, of which there was not much on offer, were inquired for, especially those of the best quality. Business in yarns was restricted to dealings for present requirements, but the volume of the transactions was considerable. Prices remain unaltered. Jute yarns are in brisk demand at last week's prices.

COMMERCIAL MUSEUM.—The managing committee of the Lille Commercial Museum has just received the following additions to the samples now on view, and which are worth the notice of English visitors:—(1) An important collection of table linen most in vogue at Buenos Ayres; (2) a varied collection of products from Algeria, Tunisia, Uruguay, Japan, and the Dutch Indies; and (3) a sample of hemp and linen harness-straps much used in Turkey, and for which therefore there is a good demand.

AMSTERDAM, 7TH APRIL, 1890.

RAILWAYS.—The shareholders of the State Railways Company are convened to an extraordinary meeting, to be held at Amsterdam on the 16th inst., to consider and, if thought fit, to sanction a modified agreement with the State for the working of certain railways, to be taken over from the Dutch-Rhenish Railway Company, dissolved. An important conference of delegates from the leading Chambers of Commerce in the kingdom has been held at Utrecht, to consider and report on the various contracts between the Government and the Dutch-Rhenish Railway Company, the State Railways Company, and the Holland Railway Company, by which the whole national railway system will be altered and centralised. A great difference of opinion manifested itself at Utrecht. The delegates from the Hague have reported strongly in favour of the new state of affairs, whilst those sent by the Chambers of Commerce at Amsterdam, Rotterdam, and Leyden have advised the rejection of the projects as framed by the Government. Utrecht reserved her opinion. These reports are to be submitted to the States-General.—The Minister of the Means of Communication, accompanied by the Director-General of the State Railways Company and the Chief Engineer of the latter, has paid a visit to Flushing, in view of the important alterations proposed at that port. The "town" station at Flushing will be merged with the harbour station. The latter will be much enlarged, and there is to be a railway hotel in the building, a thing which has been much wanted for a long time. The Directors of the "Zeeland" Company, performing the service between Flushing and Queenborough, were, of course, present at the conference, which was followed by a luncheon on board the "day" steamer "Duitschland."

EMIGRATION TO THE ARGENTINE REPUBLIC.—Mr. Reed, the Dutch Consul-General at Buenos Ayres, has issued a warning to his countrymen against their indiscriminate emigration to the Argentine Republic. He points out that the thing has been overdone, no less than 289,000 immigrants from various parts of Europe having landed at Buenos Ayres in the course of last year. This, of course, greatly impedes the placing of immigrants, and the chances of employment are further reduced by the serious crisis the country is now undergoing. Except servants, nobody, according to Mr. Reed, has now the remotest chance of finding employment on arrival at port, and vagabonds, or people of that ilk, cannot get on at all. There are already too many of them.

THE YEAST AND SPIRIT FACTORY AT DELFT.—This undertaking, the largest of its kind in Holland, has done exceedingly well in 1889. The net profit amounted to 254,764 guilders, and a dividend of 20 per cent. was declared at the annual meeting, which also authorised the directors to increase the share capital from 400,000 to 800,000 guilders, the new shares to be issued at 5 per cent. premium.

THE OYSTER CULTIVATION AT BERGEN-OP-ZOOM.—These beds are becoming gradually more productive despite low prices. The weekly average of exported bivalves exceeds 600,000. They mostly go to England.

THE DUTCH MAIL SERVICE TO INSULAND.—The Royal Mail Packets Company, whose subsidised steamers will perform the service between the islands of the Archipelago and Holland as soon as the existing contracts with the Netherland India Steam Navigation Company lapse, has held its first meeting. No results are of course forthcoming, but the chairman stated that thirteen steamers are now in course of construction. They have to be built in Holland in accordance with the law subsidising this mail service. The company has been fortunate enough to induce the Netherland India Steam Navigation Company to sell to it the entire fleet in the Archipelago, consisting of sixteen steamers, wherewith the new company will continue the local service, thus securing a monopoly with Holland, and in the mail service among the islands of Insuland as well.

THE PALACE OF INDUSTRY AT AMSTERDAM.—The company owning the Crystal Palace at Amsterdam has fared badly in 1889. Not only is there no dividend, but a loss of nearly £7,000 has to be faced, in consequence, it is said, of mismanagement, and of "bad times," as the directors aver.

TRAMWAYS IN AMSTERDAM.—An important contract has just been entered into between the town authorities and the Amsterdam Omnibus Company, which also owns the main portion of the tram system in the Dutch capital. In virtue of said agreement the company will obtain the exclusive concession for three new tram lines in different parts of the town, for which it is to pay the costs of expropriation and of lowering several bridges over canals, such costs not to exceed 1½ million guilders, say £125,000. The Town Council reserves itself the right to cancel at any time the whole concession at cost price. The shareholders of the Omnibus Company have been convened in extraordinary meeting to approve the draft of the concession and a loan project of 5,000,000 guilders.

COPENHAGEN, 5TH APRIL, 1890.

A RUSSIAN NAVAL PORT.—The projected Russian naval port at the Murman coast is hailed with much satisfaction by the Russian press. According to the present anticipations, there is a lucrative business to be done there, which is now partly neglected and partly in the hands of the more enterprising Swedes and Norwegians. The establishment of a Russian naval station will, however, put a stop to all this. As an instance of the rich yield of the ocean in those parts, it may be stated that the steamer "Vega," in the year 1888, between April 25th and May 5th, killed no less than 5,000 seals, representing a value of some 25,000 roubles.

THE SWEDISH-NORWEGIAN RAILWAY COMPANY.—It now looks as if this ill-fated undertaking might before long pass into the possession of the Swedish State, as far as the Swedish section is concerned. The terms will certainly be very different from those which the company submitted to the Swedish Government some fifteen months ago, but the company's affairs have since then gone from bad to worse. The railway has already been valued by Swedish officials some time ago, and the Lulea-Gellivara section put at something approaching 5,000,000kr. A Swedish syndicate has been formed to bring about the projected transfer, and it has been said that the Swedish Government might be disposed to go as far as 7,000,000kr.

MINING IN NORWAY.—Although English enterprise in Norwegian mining undertakings has on the whole been unsuccessful, there is no lack of fresh attempts. Some good findings of ore are reported from Saude, containing silver, lead, copper, and gold. The means of access is easy, and the position very convenient for shipping, so everything seems as promising as anyone could desire. Another English mining venture is being advertised in Norway—a Norway Mining Exploration Company. The natives seem very sceptical about it, for they think that more gold is put into gold mines than ever comes out.

MADRID, 7TH APRIL, 1890.

CADIZ SHIPBUILDING YARD.—A contract has been given to the new shipbuilding yard at Cadiz for a cruiser of 7,000 tons at the price of £600,000. This is practically the same price given for the three now building at Bilbao. At Cadiz there is very little accommodation for building ships of this size, and the steel will have to be brought from Bilbao, whilst the boiler, engines, and other machinery will have to be made either at Seville or Barcelona. It is to be feared that the contractor will be far from being able to comply with the conditions of the contract as to time. In the locality there are some hopes that the giving of the contract may help to establish regular shipbuilding at that bay for mercantile requirements, but the chances of building there at a sufficiently low cost are very slight, as labour at Cadiz is paid very high, and coals and everything else will be dearer than in the North of Spain.

THE FORREVIEJA SALT PANS.—These salt pans, which belong to the Government, are to be sold by public auction, and a well-grounded alarm has been created at Cadiz as regards the effect which its passing to private hands may have upon the salt market of the country. The fact is that Forrevieja is supposed to be able to produce more than 700,000 tons per year, and if an attempt to sell that large quantity be made the average price of salt will be much lowered in the general market. This affects very particularly the producers of salt at Cadiz, who sell their salt at about four times the prime cost. A deputation has been sent from Cadiz to the Central Government to ask that a very large price may be put on the Forrevieja Mine, so as to incapacitate the purchaser from selling cheaply. Their demand is that £2,300,000 shall be the minimum accepted, which is quite absurd.

LA VIZCAYA CO. WORKS AT BILBAO.—At the general meeting of shareholders of the large company "La Viscaya," the directors' report showed some interesting details of the rapid advance of this company. At present they have two large blast furnaces, which are to be increased to three before next June. They make coke in 108 furnaces, with such good results that the number is to be raised to 216, in which case the daily make of coke will be 440 tons. Their make of pig iron last year was 74,812 tons, 34,400 of which were disposed of in Spain, 31,500 in Italy, and the remainder in various countries. The company has three Siemens-Martin steel smelting furnaces, and the number will be increased to four by August. They have at work three rolling mills, but so far they have no plate mill. Their paid up capital is £250,000. Notwithstanding the favourable times they have not been able to pay a larger dividend than 5 per cent.

NEW YORK, 29TH MARCH, 1890.

THE COAL MARKET.—The anthracite trade has not improved. Prices are low, and are constantly being shaded, and the demand for domestic sizes is light. While the condition of the trade is bad enough, much more is made of it than necessary to influence the stock market The worst is over, and the real danger was past some months ago. Some time will pass before much improvement can be expected; but if the companies stand together, it is very probable that the end of the year will find over 33,000,000 tons sold, and at a fair average profit.

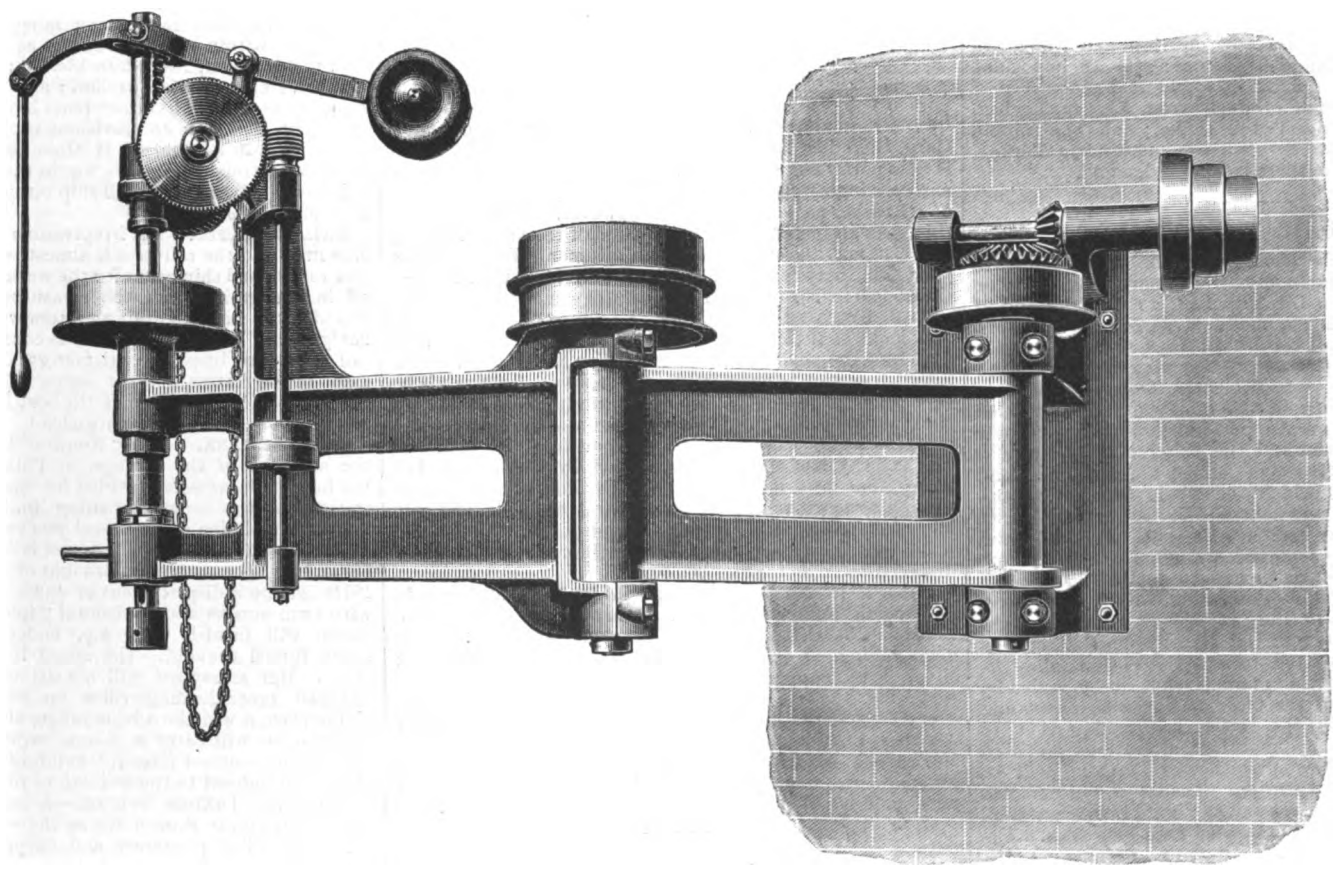
OCEAN FREIGHTS.—There has been a decided drop in ocean freights which have been strong for nearly two years. The *New York Commercial Bulletin* in a long article on the subject says that rates have fallen from New York to Liverpool within a month or two as follows: Grain, from 5½d. to 4d.; flour, 18s. 9d. to 13s. 9d.; oil cake, 17s. 6d. to 12s. 6d.; cheese, 35s. to 30s.; and cotton, ¼d. to ⅛d. Freights to nearly all other ports have made a similar decline, but the rates on provisions to Liverpool are quoted higher than in February. If there is any such weakness in outward freights as there was in the early parts of 1888, it is very likely that we shall ship bituminous coal and coke to England this year.

RAIL OR WATER.—The irrepressible conflict between the lake lines and the railways is almost ready to recommence. The east-bound shipments for the week show a large falling off in the grain traffic, the reason being that it is being stored in the Chicago grain elevators waiting the opening of navigation. In spite of numerous conferences between the rail and lake lines, no satisfactory disposition has been made of the matter, and the season bids fair to open with a renewal of the old policy of the boat lines cutting rates to any figure necessary to secure a load.

THE "NEWARK."—The "Newark" has been launched at the shipyard of the Cramps, in Philadelphia. She was the first of the vessels provided for under the last administration, and was known as Cruiser No. 1. The contract time for the completion of the vessel was two years, and expired on October 27th last. The vessel is 310ft. long, 49ft. 2in. beam, and has a maximum draught of 20½ft. and a mean of 18½ft., giving a displacement of 4,083 tons. She is fitted with twin screws and horizontal triple expansion engines, which will furnish 6,000 h.p. under natural and 8,580 under forced draught. The speed is expected to be 18 knots. Her armament will consist of twelve 6in. high-powered breechloading rifles on centre-pivot mounts, giving them a wide broadside range, and in her secondary battery she will carry a dozen rapid-fire and machine guns. The contract price for building the "Newark" was $1,248,000, subject to the deductions for loss of time.

BUILDING TRADES STRIKE.—A general strike in the building trades in Boston during the season of 1890 seems inevitable. The plasterers and carpenters recently demanded that eight hours shall constitute a day's work after April 1st and May 1st. Both trades expected to secure their demands without trouble, but the Carpenters and Builders' Associations (Masters) have voted not to grant the eight hour demand. The association also determined that no members should sign a contract that did not contain a strike clause. The workmen seem determined, and say they will resort to extreme measures to obtain what they ask.

BOUNTIES FOR AMERICAN VESSELS.—This question is regarded as one of the most important matters that will engage the attention of this Congress. The House Committee on Commerce and Fisheries has decided to recommend a bounty on American vessels, both sail and steam, engaged in trading between America and foreign ports of thirty cents per ton per thousand miles; it will apply to all vessels now or hereafter built.



FORTIFICATIONS.—The Appropriation Committee of the House has reported the Fortification Bill, the aggregate of which is $4,521,678. One of the items is $250,000 for breechloading cast-iron hooped 12in. mortars. The report says that one of these mortars has been fired 400 rounds without sensitive detriment with a charge of 80lb. of powder and a shell of 630lb., giving a range of six miles. An item of $25,000 for steel shells indicates a purpose on the part of the War Department to follow up the European experiments with high explosive shells of steel armour-piercing projectiles, for which an appropriation of $100,000 is made.

THE IRON AND STEEL TRADE.—The downward tendency of the market has been very marked during the past couple of weeks, but the indications now are that prices are very near the bottom, and that a reaction is not far distant. At the present, however, the feeling is unsettled, and buyers are inclined to take small lots only until the outlook becomes clearer. In pig iron the weakness in prices has not brought in any larger amount of business so far, although negotiations are in progress which may lead to heavy transactions at any time. The fall in prices is not due to any special falling off in consumption, but to the steady increase in production, which now is at the rate of over nine million tons per year. Sales during the week have been generally at $19, $18, and $17 delivered for the three grades, but in special cases these figures have been shaded considerably. There is still some hesitancy among buyers, but the chances are favourable for an early resumption of activity, if not of better prices. Some increase in the volume of business in manufactured iron is to be noted along the entire line, but prices have continued to drop. A larger business has been done in steel rails than for some time past; lots amounting to upwards of 20,000 tons have been taken at prices about $34·50 per ton at mill. There is still a large amount of business under consideration. The market for billets is unsettled from the continued pressure from holders of speculative lots. Prices are nominally $32·50 to $33 per ton delivered, but orders could probably be placed at something less.

WALL BRACKET RADIAL DRILLING MACHINE.

CONSTRUCTED BY MESSRS HETHERINGTON & CO., ENGINEERS, MANCHESTER.

RADIAL DRILLING MACHINE.

THE machine of which an illustration is given above is of novel design. It is not uncommon to find radial drill arms hinged to a wall, but the radial adjustment is usually obtained by the employment of a sliding saddle carrying the drill spindle. This, of course, adds materially to the cost of production. In the machine illustrated the arm is in two pieces, which are coupled in the centre by means of a pin. The arm is pivoted on a pin, which passes through ears on a wall bracket of the usual type. The drill spindle is carried at the outer end of the second half of the arm, and is 1¾in. diameter, with a vertical feed traverse of 9in. The feed may be either manual or self-acting, and the spindle is balanced as shown. The driving power is derived from a speed cone, bevel wheels, and a pulley which runs loosely on the pin which forms the inner pivot of the arm; from it a strap passes to the double pulley which is fixed on the centre hinge pin, and from there a second strap drives the spindle. Thus whatever position the arm may be in the distance of the driving centres is preserved and the straps are always tight. The double hinge permits of the drill spindle being easily brought over a hole in any position within 6ft. of the wall bracket, while the construction adopted gives a simple and inexpensive tool which will be very serviceable to many engineers. The makers are Messrs. Hetherington & Co., Ancoats Works, Manchester.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the eighteenth ordinary meeting of the Session, on Tuesday, the 1st inst., Sir John Coode, K.C.M.G., President, in the chair, the paper read was "On the Barry Dock Works, including the Hydraulic Machinery and the Mode of Tipping Coal," by Mr. John Robinson, M. Inst.C.E.

Barry Dock was situated on the north shore of the Bristol Channel, between Barry Island and the mainland of Glamorganshire, seven miles in a direct line south-west of Cardiff. The site chosen for the dock occupied the eastern portion of the channel, which formerly ran between the island and the mainland. An Act of Parliament to authorise the construction of the dock, and the railways connected therewith, obtained the Royal Assent on the 14th of August, 1884. The undertaking comprised a tidal basin of 7 acres, a dock of 73 acres, and a timber pond of 24 acres. The entrance to the dock was at the eastern end of the island, under the shelter of the high land of Nell's Point. This excellent natural shelter was supplemented by two outlying converging breakwaters. The tidal range was 36ft. at ordinary spring-tides, increasing to 40ft. at extraordinary springs; and 19½ft. at ordinary neaps, diminishing to 16ft. at extraordinary neaps. The dock was not fed with water from any river. The width of the entrance between the masonry walls was 80ft., and gave access to the basin. In the entrance was placed a single pair of wrought-iron gates, and the dock not being exposed to heavy seas, there were no gates pointing outwards. The passage between the basin and the dock also had a width of 80ft.

The dock was 3,400ft. in length, the maximum width being 1,100ft., divided at the western end by a mole into two arms, the full width being left at the eastern end for a length of 1,600ft., where vessels of the largest class could swing. The bottom of the dock, which was not puddled, was 20ft. below mean sea-level. The mole was 1,300ft. in length and 200ft. in width, with pitched slopes of 1¾ to 1 on the north side, and of 2 to 1 on the south side. Along the northern side of the dock were 11 high-level tips, and on the northern side of the Mole were 3 low-level fixed tips, and masonry towers for two others had been built. Two more low-level tips were stationed on the south side of the dock, and one at the western end. To prevent the basin and dock being flooded whilst the temporary stone dam was removed a caisson was erected, which could be used for future requirements.

The breakwaters were formed of rubble excavated from the basin and railway cuttings, and the sea slope was protected by blocks of mountain limestone, weighing from 4 to 7 tons each. At the head of the west breakwater there was erected a cast-iron tower, 30ft. in height, the diameter at the base being 7ft. 9in., and at the top 6ft. 6in., with a spiral staircase inside. In the tower was placed a fourth-order dioptric occulting white light, visible in clear weather at a distance of 10 miles.

The hydraulic power was obtained by means of two pairs of compound horizontal condensing pumping engines of the tandem type. The boiler pressure was 80lb. per square inch, and condensing water was obtained from, and returned to, the docks through pipes 15in. in diameter, by the circulating-pumps. Another hydraulic engine-house was in course of construction at the north-west end of the dock.

The entrance from the sea into the basin, and the passage between the basin and the dock, were each provided with a pair of wrought-iron gates having a span of 80ft. and a rise of 20ft. There were six sluices in each leaf, having a combined area of 100 square feet. These were worked from the top by direct-acting hydraulic cylinders and pistons. The gates at the entrance were opened and closed by hydraulic power, chains being dispensed with. The water was admitted to a direct-acting hydraulic cylinder having a piston 2ft. 5¾in. in diameter, and a ram 1ft. 9in. in diameter, with a stroke of 25ft. 9in., attached direct to the gate, the cylinder being in three parts of cast-steel. Trunnions were cast on the cylinders, projecting above and below, and pivoted in saddle bearings, which also had trunnions on their sides, and these pivoted in bearings fixed to the walls of the ram chamber, thus permitting the cylinder to oscillate both horizontally and vertically. The hydraulic rams were of sufficient strength to resist shocks of waves, and to hold the gates rigidly during movement. The passage gates were worked in the same manner as those at the entrance; but in this case the ram was attached to a radius arm near the top, with a slide against the back of the gate, the other end of the arm working on a pin in the holding-down bracket over the top of the heel-post. As the power required was less, the diameter of the piston was only 2ft. 1½in., and that of the ram 1ft. 6in., with a stroke of 16ft. 7in. The cylinder for the passage-gate machine was of iron, cast in one length, and tested to a pressure of 2,400lb. per square inch. The ram was also of cast iron, and the whole machine was arranged in a similar manner to that for the entrance gates. For the protection of the gates stout chain-cables and wrought-iron box booms were placed in front of the masonry. To prevent the gates rising and floating away a cast-steel holding-down bracket was provided at the top of each heel-post. The ordinary time occupied in opening the gates was one minute and a half, and the same in closing; but those at the passage occupied less than a minute in opening, and the same in closing.

The following modes were adopted at Barry for the shipment of coal, where it was shipped both from high and from low levels. On the high-level the trains were backed into curved sidings intended for full waggons, where the engine left them. These sidings were on gradients of 1 in 233. No stop-chocks were employed, neither had they been found necessary. The loaded waggons were sent from the collieries with the doors uphill, to prevent their opening on some of the steep inclines in the valleys, and did not, therefore, require to be turned for tipping when shunted into the sidings, thereby saving both time and labour. The waggons were drawn forward and run one by one on to the weigh-

Digitized by Google

bridge, and afterwards drawn on to the coal-tip by means of another hydraulic capstan. The coal-tips consisted of masonry towers, 30ft. square, on which were erected wrought-iron framings, braced together by angle tee, and bar irons. This framing served to support the wrought-iron guides for the cradle. The latter was provided with the necessary tip-up table, hinged in front, and worked by hydraulic power, by means of a cylinder hung on trunnions to girders underneath the cradle which travelled with it, and capable of tipping loads up to 19 tons. The tips were provided with coal-shoots, anti-breakage cranes, boxes, &c. The shoot was tapered towards the point to check the sliding of the coal, and had a single door across near the end for regulating the same. In the bottom plate of each shoot were two iron bar screens for separating the small coal when required. On the underside of the shoots, immediately below the screens, were hinged doors to allow of single-screening, double-screening, or the passage of the coal unscreened. At one of the high-level tips 400 tons had been shipped in one hour in the ordinary course of working.

The tips on the low level differed from those on the high level, insomuch that waggons were received into the hoists at quay level, and the empty waggons were returned from the tip at the same level. The waggon had thus to be lifted the required height for tipping. A movable tip was in course of construction for the high-level, which would run on rails along the quay for a distance of about 50ft. each side of the centre of approach, and could be used in connection with a fixed tip. The tip was moved by a hydraulic engine geared to the travelling wheels. There was also a movable tip in course of construction for the low level. The passage was crossed by a rolling bridge, worked by hydraulic power, carrying a single line of railway and forming part of a roadway. There were eleven movable cranes, capable of lifting from 30 cwt. to 4 tons, for loading and discharging cargoes of vessels lying along the quay wall and against the timber jetties at the east end of the dock. The cranes were of the elevated type, and constructed on a pedestal of wrought-iron plate, with an arch underneath for the waggons to pass while the cranes were at work. The dock and sidings were lighted by electric light. The engineers of the dock works were Mr. John Wolfe Barry, Mr. T. Forster Brown, and Mr. H. M. Brunel. The author was the resident engineer.

SHIPBUILDING NOTES.

ON the 5th inst. the s.s. "Clyde," a vessel of 5,650 tons, was launched by Messrs. Robert Napier & Sons, Govan. This vessel is one of four which the same builders have built for the Royal Mail Steam Packet Company, London, to be employed in the service of this company in the West Indian, Brazil, and River Plate trade. The triple expansion engines are of 7,000 horse power. The dimensions of the vessel are:—Length, 456ft.; breadth, 50ft.; and depth, 33ft. 4in. The ship has been built with a view to meet the requirements of the Admiralty as an armed cruiser. There is accommodation in all for 1,000 passengers. The ship is fitted throughout with electric light, and heated throughout by steam.

ON the 5th inst., the steamship "Federal" was launched from the yard of Messrs. W. Doxford & Sons, of Pallion, Sunderland. She has been built to the order of John McIlwraith, Esq., of Melbourne. The principal dimensions are:—Length between poops, 290ft.; breadth, extreme, 40ft.; depth, moulded, 22ft.; and deadweight, 3,425 tons on 20ft. draught. The engines are of the triple-expansion type, the cylinders being 23in., 37in., 60in. in diameter, and the stroke 42in. She is fitted with steering gear amidships by Messrs. Amos & Smith, of Hull; 5 steam winches, with special coal drums, by Messrs. Welford Bros., of Pallion; special apparatus by Messrs. Brown Bros., of Edinburgh, for the quick discharge of coal cargo, and a steam windlass by Messrs. Clarke, Chapman, & Co., of Gateshead.

ON the 7th inst. Messrs. Scott & Co., Greenock, launched the steel screw steamer "Priam" for the Ocean Steamship Company. The vessel is intended for the China trade. The dimensions are:—Length, 335ft.; breadth, 38½ft.; depth of hold, 27ft.; and tonnage, 2,800 tons.

ON the 7th inst. the s.s. "Brand" was launched by Messrs. Robert Duncan & Co., Port Glasgow. The length of the vessel is 270ft.; width, 37ft.; depth, 23ft.; and the net register tonnage, 2,000 tons. The ship has been built to the order of Mr. Kundsen, Porsgrund, Norway. Messrs. Muir & Houston are making the triple-expansion engines.

ON the 8th inst. Messrs. Fleming & Ferguson, shipbuilders and engineers, Paisley, launched a steel twin-screw steamer with overlapping propellers. The dimensions are:—Length, 220ft.; breadth, 31ft.; depth, 15ft. 6in. She is to be fitted by the builders with two sets of their patent quadruple expansion engines to work with boiler pressure at 200lb. per square inch, and to indicate 1,200 h.p. This vessel has been built to the order of Messrs. J. & A. Brown, New South Wales, for their Colonial trade. As she left the ways she was named the "Duckinfield."

Notices of Meetings.

THIS WEEK.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Saturday, April 12th, at 5.45 p.m. Discussion on Mr. R. L. Weighton's paper on "The Institution's Rule for the Normal Indicated Horse-power of Marine Engines and Boilers"; Discussion on Mr. Bergström's paper on "The Structural Strength, &c., of Cargo Steamers of Different Types"; Paper on "The Weight of Machinery in the Mercantile Marine," by Mr. William Boyd.

THE JUNIOR ENGINEERING SOCIETY.—Saturday, April 12th. Visit to the Leyton Sewage Disposal Works. Meeting at the Town Hall, Leyton, at 4 p.m.

NEXT WEEK.

SOCIETY OF ENGINEERS.—Monday, April 14th. Paper to be read on "Weighing Machinery and Automatic Apparatus in Connection Therewith," by Mr. William Henry Brothers.

INSTITUTE OF MARINE ENGINEERS. Tuesday, April 15th, at 7.30 p.m. Paper on "Blowing Up the Old Dock Wall at the New Entrance, Royal Albert Dock," by Mr. Jos. Thomas; Paper on "Paddle Engines," by Mr. Buckwell.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, April 15th, at 8 p.m. Ordinary Meeting. Paper to be read: "The Application of Electricity to Welding, Stamping, and other Cognate Purposes," by Sir Frederick Bramwell.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, April 16th, at 7 p.m. Papers to be read: "The Cold Period at the Beginning of March, 1890," by Charles Harding, F.R.Met.Soc.; "Note on the Whirlwind which occurred at Fulford, near York, March 8th, 1890," by J. E. Clark, B.Sc., F.G.S.; "On the Possibility of Forecasting the Weather by Means of Monthly Averages," by Albert E. Watson, B.A., F.R.Met.Soc.; "Rainfall of the Globe," by W. B. Tripp, M.Inst.C.E., F.R.Met.Soc.

SOCIETY OF ARTS.—Wednesday, April 16th, at 8 p.m. "Old and New Fashions in Typography," by Talbot B. Reed.

ROYAL INSTITUTION OF GREAT BRITAIN.—Friday, April 18th, at 9 p.m. Sir Frederick Bramwell on "Welding by Electricity."

PRICES CURRENT, 9TH APRIL, 1890.

Quotations at per ton, unless otherwise specified.

METALS.

		£	s.	d.		£	s.	d.

„ Australian		90	0	0	„	90	10	0
„ English Ingots		95	0	0	„	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: The Easter holidays interfered with business, buyers showing a general inclination to defer operating. In our last report on the 2nd Chili bars were quoted £47 12s. 6d. to £48 cash, but a firmer market on the 3rd caused prices to advance to £48 5s. to £48 12s. 6d. After the holidays these prices were maintained, but values declined to-day to £47 17s. 6d. to £48 5s., a small trade being reported. The demand for manufactured continues slack at £61 sheets, £64 bottoms.

TIN: Although the visible supply of tin for Europe has decreased over 700 tons during March, it has had no appreciable effect on prices. The business transacted is still unimportant, with quotations somewhat easier.

LEAD continues inactive, without alteration in price.

SPELTER keeps very quiet, and prices are rather easier.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: With the intervention of the Easter holidays since our last there is little of interest to report. Soda ash holds its strong position, and soda crystals are very firm, but caustic soda is somewhat easier. For other chemicals there is only a moderate inquiry, and prices are unchanged.

HOME INDUSTRIES.

LONDON, 10th April, 1890.

The Money Market.—Though at the beginning of the week there was an active demand for money for the repayment of the loans obtained from the Bank of England in the two preceding weeks, money has now become easier. The position is favourable. Gold is coming in plentifully from abroad, and the Consol and other dividends, which have been distributed slightly later than usual through the incidence of Easter, will soon drift back to Lombard Street for employment. Discount rates are easy in view of this. The stock markets have hardly thrown off the holiday influence yet, but, though business is limited, prices are good. Home railways are firm on holiday traffics. Foreign securities are generally good. Egyptians are rising on the renewal of the conversion question, and other international stocks are firm. Argentines have had another severe fall, the gold premium at Buenos Ayres continuing to rise. The American railway market is dull and featureless in spite of New York support. Nitrate securities still fluctuate rather wildly. South African gold shares show a continued disposition to recover. Miscellaneous and industrial shares are inactive.

Companies.—The following companies have been registered since our last report:—The Idaho Syndicate, Ld., with a capital of £500, to investigate the merits of the Idaho Mining and Irrigation Co.; The London Tinplate Co., Ld., with a capital of £50,000; The Greta Collieries, Ld., with a capital of £200,000; The International Exploration Co., Ld., with a capital of £20,100; Penarth Slate and Building Material Supply Co., Ld., with a capital of £5,000; The New England Breweries Co., Ld., with a capital of £410,000; Ottoman Paper Manufacturing Co., Ld., with a capital of £325,000; South of England Coal-Boring Syndicate, Ld., with a capital of £2,000; The Netherseal Colliery Co., Ld., with a capital of £32,000; The Kelsterton Brewery Co., Ld., with a capital of £100,000; Lorillard Brickworks, Ld., with a capital of £400,000; The African Estates Agency, Ld., with a capital of £25,100, to acquire claims, mines, &c.; The International Exhibition of Mining and Metallurgy; Newcastle (Natal) Collieries and Estate Co., Ld., with a capital of £100,000; Brod Brewery Co., Ld., with a capital of £10,000.

Workmen's Exhibition.—There was opened, on Saturday, at the Central Hall, Holborn, a Workmen's Exhibition, which had been promoted by the Club and Institute Union, and which closed yesterday. There had been a flourish of trumpets over the inauguration of this movement, and on the face of it the idea was a good one. The promise was, however, not fulfilled, and though there was a fair number of exhibits, there was little calling for attention beyond some cabinet work and art exhibits, the latter of various qualities.

Exhibition Lighting.—The Military Exhibition at Chelsea will be lighted by Messrs. Davey, Paxman, & Co., and the French Exhibition at Earl's Court by the Gülcher Company.

Slippery Pavements.—At a meeting of the Society of Arts, on the 27th ult., it was mentioned that Mr. J. Compton Merryweather, of Long Acre, has recently taken out a patent for a pavement, according to which he inserts lead plugs or strips in paving to render it less slippery.

The Institution of Mechanical Engineers.—A meeting of this Institution will be held on Thursday and Friday evenings, the 1st and 2nd prox., at the rooms of the Institution of Civil Engineers, Great George Street, Westminster. On Thursday evening, the President, Mr. Joseph Tomlinson, will deliver his inaugural address, and then the following paper will be read:—"Research Committee on Marine Engine Trials' Report upon Trials of three Steamers, 'Fusi Yama,' 'Colchester,' 'Tartar,'" by Professor A. B. W. Kennedy, the discussion upon which will be continued on Friday evening.

The Royal Institution.—According to the present arrangements for afternoon lectures, the Hon. George C. Brodrick will begin a course of three lectures, on "The Place of Oxford University in English History," on Tuesday, the 15th; Professor C. V. Boys will begin a course of three lectures, on "The Heat of the Moon and Stars," on Thursday, the 17th; and Captain Abney will begin a course of three lectures, on "Colour and its Chemical Action," on Saturday, the 19th. The evening meetings will be resumed on Friday, the 18th, when Sir Frederick Bramwell, Bart., will give a discourse on "Welding by Electricity."

Macmahon's Electric Check System.—A new electric check apparatus for use where liquors are sold is being introduced into this country by Macmahon's Patent Electric Check System, Limited, 1, Imperial Buildings, Ludgate Circus. The apparatus is meant for measuring the amount of liquor served at the bar, and for checking and recording the sales and receipts. The amount served depends on the position of a knob, and by means of a series of electric contacts the amount is recorded on a pointer and dial. For each pennyworth of liquor served a distinct contact is made, and the current which then passes is made to excite an electromagnet and thus turn a ratchet wheel through one notch. In this way the total amount of liquor served is checked.

Change of Address.—Messrs. E. L. Berry & Co., late of 8, Wardour Street, electrical engineers and contractors, have removed to temporary premises, 45, Gerrard Street, Wardour Street, until the completion of their new premises.

MANCHESTER, 10th April, 1890.

The Merchandise Marks Bill.—The Bill promoted in Parliament by Mr. Broadhurst, and supported by several other members, is likely to meet with strenuous opposition from the mercantile community here. One of its provisions declares that all pieces of cloth made in England shall be stamped with the name of the manufacturer and the town in which his works are situated. This, it is clear, would seriously damage the trade of the merchants; in many cases, indeed, it would practically close it. The Bill provides that the same mark shall be re-stamped on the cloth after its erasure in the processes of dyeing, bleaching, or printing. This action would be so detrimental to the trade of the district as practically to necessitate it being remodelled. It would not prevent fraud, but would simply throw into the hands of manufacturers a power which would enable them to reap the benefit of the labour and expenditure of the merchants in building up their extensive foreign business. The Manchester Chamber of Commerce is pledged to opposition, except to one clause appointing a Public Prosecutor under the Act, which it supports.

The Iron Trade.—The Easter holidays have somewhat disorganised the market, but there is no sign of any improvement in the demand. In the face of the continual depression in the price of warrants, users do not appear to care to come into the market, and there is in addition a decided lull in the volume of orders coming forward for engineering material. These two causes are making consumers in this market very chary about entering into new obligations, and an opinion is being expressed that an improvement is hardly likely to occur during the summer months. The quarterly meetings to be held this week are expected to result in a drop in the quotations for finished iron, the price of which has been much cut by middle holders, although makers still profess themselves indifferent to new business except at full rates. There is, however, not sufficient weight of work being offered in any department to test prices seriously, and all quotations are practically nominal.

The Manchester Technical School.—A small exhibition of the work of students has been held at the above school during this week. The work in the wood-working department shows promise, some of the articles being well and efficiently made. It cannot be said that anything more than promise is shown generally, but the work of different students is very even in quality. In the art designs shown there are some clever specimens, and a noticeable feature about one or two of them is the skill shown in adapting the design to the class of material and manner in which it is to be worked out. This is a point often lost sight of in decorative designs, and it is the more noteworthy in this case because of the necessary limitations of the school. Without showing any wide departure from the conventional style of design in all cases, there are several specimens of original work which have the merit of being carefully thought out. On the whole, the exhibition is distinctly creditable, and gives great promise of better things when the school possesses greater facilities.

The Linen and Jute Trades.—Attention is now principally centred in fancy goods, and heavy makes generally are dull. Linens are in very poor demand, the only cheerful outlook being for shirting and fronting descriptions, which promise to move off more freely in the course of a week or so. On Tuesday there was a rush both of travellers and orders in some departments, and until we have recovered from the effects of the holidays it will be difficult to gauge with any degree of exactitude the character of the demand. The only cheerful feature at the moment is that American buyers are now looking round the market preparatory to placing their orders, and it is anticipated that, in view of the threatened advances in the United States tariff, houses on the other side will import to a more than average extent. The object of the contemplated legislation is a mystery to every one, as the United States have no linen industry to protect, and higher duties can therefore benefit no special class, while, on the other hand, they impose an additional burden on the nation at large. Certainly this country will not be called upon to bear the extra cost of increased duties, as there is no home competition to contend with. Shipments to the South American republics still continue to be of an unsatisfactory nature, owing to fiscal complications amongst our customers in that region. Sheetings, drills, and other makes are quiet. There is no change in towels, and in fact the whole of the home trade may be described as featureless, while the shipping demand nowhere displays signs of activity.

GLASGOW, 10th April, 1890.

Holidays.—The coincidence of the Easter holidays with the Glasgow spring holiday caused a cessation of business for at least three days. The works were closed only on Monday, but the Bank holidays on Good Friday and on Monday put a stop to business from Thursday till Tuesday. The number of excursionists who left the city on the spring holiday was larger than ever before. All of the railway stations were taxed to their utmost capacity, and old rolling stock was called extensively into requisition. On Tuesday there was little business doing on any of the Exchanges.

Engineering.—The phenomenal success in floating two engineering concerns as limited liability companies quite recently has encouraged several other local firms to adopt the same mode of carrying on their business. Among these are mentioned the Anderston Foundry, and the well-known engineering firm of Messrs. Duncan Stewart & Co.

Shipbuilding.—The elevating ferry steamer being built for the Clyde Trust by Messrs. W. Simons & Co., Renfrew, will shortly be launched. It will, however, be some time ere the necessary preparations for the reception of the steamer are completed at the harbour.

Scottish Railways.—It is reported that the North British Railway Company has acquired all of the shares of the Galloway Steam Packet Company, Leith, saving a single holding, and that henceforward the steamboats plying on the Forth will be run in connection with the North British Railway.—The Forth Bridge is apparently as great an attraction to the tourist as ever. Monday being a holiday in Glasgow and Edinburgh, thousands of people made their way to Queensferry by rail and brake.—The Edinburgh Corporation has finally decided to oppose the Bill of the Caledonian Railway, by which it seeks powers for the construction of an underground railway in Edinburgh.

Coal.—Continental advices confirm the anticipation of a few weeks ago that coal, instead of going up, was tending downwards.

(From our own Correspondents.)

LIVERPOOL, 9th April, 1890.

The Late Dock Strike.—Work along the whole line of docks has assumed its normal condition, and there are no visible signs of the late struggle; a large proportion of the old hands have resumed work, and the imported hands have returned to their homes. The families of the strikers are, however, still suffering from their recent hardships, and much is now being done to relieve their sufferings, subscriptions for large amounts arriving daily from all parts of the country. An unfortunate difference has occurred between the stevedores and the men as to the number of hours to be worked at night in a few of the docks, but this will, no doubt, be amicably settled.

Engineering and Shipbuilding.—Most of the shops and yards on both sides of the river continue to be very busy, and although the Easter holidays are generally taken advantage of to overhaul the machinery and plant, and effect any necessary repairs, many of the shops were this year compelled to work through the holidays on account of pressure of work. The weather being exceptionally fine, the city was thronged with excursionists, and the traffic on all the river boats, and the Mersey and Wirral Railways, was enormous.

LEEDS, 9th April, 1890.

The Iron and Steel Trades.—An extensive amount of business was done in the three months just ended, but the second quarter of the year opens rather quietly, causing a little anxiety as to the future. The depression is greater than was anticipated, and there is no doubt that until a change takes place both the Scotch and English iron markets will be watched with interest by local manufacturers. There is great scarcity of fresh orders, both in the manufactured iron and steel trades; producers in nearly all cases are working out their orders taken last year, and do not get in new work, consumers being evidently waiting for prices to come down. Were it not for old contracts some of the makers would be in a difficulty about giving full employment to their workpeople. Overtime is now the exception, instead of the rule. Orders are not coming forward freely at the engineering works, yet here again the men are well employed, the Amalgamated Society of Engineers in Leeds having very few unemployed men on its books. The agricultural machinery trade remains quiet, there practically being no new business coming to hand. Machine tool makers are still very active. The unsettled state of the pig iron market has caused a considerable falling off in the demand for cut steel and iron nails, though the prices are remarkably firm. It is rumoured that the engineers of the district are going in for an advance of 2s. per week in their wages.

The Coal Trade.—The demand for all kinds of fuel is only moderate, the reason being that many manufacturers and householders obtained extra supplies in anticipation of the recent strike. All the Yorkshire pits are again at work with one exception. The Yorkshire miners, speaking generally, have passed resolutions thanking the National Federation of Miners for securing the advance of 40 per cent. in wages, and approving of the Eight Hours Bill.

SHEFFIELD, 9th April, 1890.

The Coal and Coke Trades.—Manufacturing fuel of all kinds has advanced from 6d. to 1s. per ton during the past week, owing to the extra 5 per cent. given to the colliers. There has been no further advance in house coal, and consumers are using as little as possible, owing to the present high rates; 17s. is a high price to pay for coal almost on the pit banks. Coke of all kinds still holds a good position in the market, and prices are firm at recent quotations; 28s. per ton for coke of best quality is now paid here. There is an opening for a simple and effective coke-washing apparatus capable of being worked by a labourer, and adapted to deal with the ashes from boiler-furnaces.

Digitized by Google

THE IRON AND STEEL TRADES.—The rolling mills continue to find plenty of work to keep them employed continuously night and day. In order to reduce the cost of reheating ingots, some of the more energetic mill owners are considering the question of employing more economical types of furnace. A very difficult section of tram rail made in hard steel is being rolled here, to the order of a Continental house. The heavy trades, such as armour plates and shaft forging, are at present fairly off for work. Steel castings are also in good demand. In smaller wares, such as mining tools, agricultural implements, castings, forgings, &c., the workmen are fully employed. Files of all classes are in excellent demand, not alone for the home market, but also for export to the Continent. France, Germany, and Italy are all good customers. Germany continues to be a good customer for file-cutting machines. One firm here have supplied a single house in Germany with more file cutters of their own make than are to be found in all this district, all of the very latest pattern and best construction. Engineers have had their hands full to get their repairs done in time for restarting after the holidays.

SHEFFIELD SOCIETY OF ENGINEERS.—On Saturday evening a paper was read before this Society by Mr. B. H. Thwaite, of Liverpool, on "The Development of the Open-Hearth Steel Furnace." Mr. Thwaite commenced by giving a historic outline of the manufacture of steel, followed by a brief summary of the chemical and thermic principles underlying the open-hearth process. He dealt with the origin and rationale of the recuperative principle, the structural development of the open-hearth steel furnace, the thermic efficiency of the furnace, the production and application of gaseous fuel, the structural and mechanical agents of the furnace, and the latest form of acid and basic furnaces. The lecture was practically illustrated by a model of a basic open-hearth furnace, sent by Mr. James Riley, of the Steel Company of Scotland, showing his neutral course for dividing the lime from the acid part of the furnace. Mr. Riley also sent a number of samples showing the change in the chemical and physical samples of steel and slag taken each hour from the bath. Some exceilent samples of steel were sent by Sir B. Baker, showing the sort of material used in constructing the Forth Bridge. Mr. Percy Gilchrist forwarded samples of open-hearth steel, showing the entire process of open-hearth steel production. Mr. Gilchrist sent some of the best samples of refractory bricks to be found in this country. Mr. Le Neve Foster, of Bolckow, Vaughan, & Co., Middlesbrough, sent a working model of his reversible gas valve.

NORTH STAFFORDSHIRE, 9TH APRIL, 1890.

THE EASTER HOLIDAYS.—Manufacturers are taking advantage of the Easter holidays for general repairs, and the whole of the ironworks in the district are standing idle. Blast furnaces have to be kept going, and colliery managers have some difficulty in keeping up the needful supplies. The collieries do not start till to-day, and a number of men are absent the whole of the week. The potters, in many cases, close their works till Monday next.

THE IRON TRADE.—Considerable anxiety is experienced as to the course of trade at the local quarterly meeting which has been called for to-day and at the meeting at Birmingham on Thursday. It is feared that prices will show further signs of weakness. It is understood that a prominent local firm of ironmasters is in difficulties, and about to call a meeting of its creditors, speculations in pig iron having turned out adversely owing to the heavy fall in values.

THE COAL TRADE.—It is difficult to see how the second instalment of 5 per cent. advance in wages is to be forthcoming on the 1st of August, as prices of all classes of manufacturing fuel are declining rapidly, and colliery proprietors will soon find that selling prices are actually below the cost of production, which has already been enhanced to the extent of 35 per cent. for labour, and to nearly an equal extent for stores, &c.

CARDIFF 9TH APRIL, 1890.

GENERAL TRADE.—Business during the holiday season has been entirely suspended, and there is nothing of importance to record. Inquiries for steam coal have been numerous, but until colliery owners can exactly estimate the loss of output, they are not disposed to make binding offers. Quotations remain firm at last week's figures. Arrivals of pitwood and iron ore have been heavy, and considerable detention has resulted from the small amount of work done by the discharging workmen. Rubio ore is quoted at 16s. 3d. to 16s. 9d. c.i.f. Cardiff and Newport.

BARROW-IN-FURNESS, 9TH APRIL, 1890.

HEMATITE IRON.—There is a rather better tone in the hematite market, although the business doing has not increased. Prices are a shade firmer, hematite warrants being at 59s. 6d. per ton. Makers are asking 70s. for mixed Bessemer numbers, and 69s. for No. 3 forge and foundry iron, and they cannot produce iron at lower prices. A further reduction in warrant stocks has been made to the extent of over 2,000 tons. The output of pig iron is not only being reduced by the blowing out of furnaces, but by transferring two of the furnaces from hematite to spiegeleisen blast. It is probable that makers will further reduce the output of their works, as there is a mutual understanding among them of the necessity of combined efforts.

STEEL.—There is a better inquiry in the steel trade, but the business which has lately been done is not on a large scale, although prices are lower. Heavy sections of rails have gone down to £5 10s. per ton; light rails are at £5 15s., and colliery rails are firm at £8 per ton. There has also been a decline in the value of steel ship plates, which are quoted now at £7 10s., and angles at £7 per ton. Steel boiler plates are in brisk inquiry at £8 10s. There is a better demand for tinplate bars at £6 10s. per ton. It will be necessary for makers to book some orders soon, even at low prices, if they are to keep their works fully employed.

SHIPBUILDING AND ENGINEERING.—No new orders are reported in the shipbuilding and engineering trades, which are, however, very briskly employed. It is believed that with cheaper material shipowners would be disposed to place some large orders which were withheld some time ago in consequence of the heavy cost of tonnage.

IRON ORE.—There is a weaker tone in the hematite iron ore trade, and prices are easier, at from 12s. 6d. to 16s. 6d. per ton net at mines.

COAL AND COKE.—There is an easier tone in coal and coke, and as these are the conditions necessary for making cheaper iron, there is some hope of relieving the present crisis, in which makers find themselves undersold to the extent of fully 10s. per ton.

MIDDLESBROUGH, 9TH APRIL, 1890.

PIG IRON.—The quarterly meeting of the North of England iron trade was held yesterday on 'Change, but there was a very small attendance. The holidays have been taken advantage of, seeing that business was so very quiet. The price of pig iron, however, did not suffer, for it had advanced 2s. 6d. since the previous weekly market day, and eventually reached 53s. This was on account of the heavy drain upon public stores and the increasing shipments. In hematite, on the contrary, there was a heavy fall. Hematite pigs, though quoted at 70s., can now be had at 59s. This has caused the firm which owns the Linthorpe Iron Works to announce their intention of damping down two furnaces, as the iron cannot be made for the selling price.

IRONMASTERS' RETURNS.—The returns announce that the make of pig iron for the month of March amounted to 244,889 tons, as against 221,517 tons in February, being an increase of 23,372 tons. In Cleveland iron only—that is, not including hematite, basic, and spiegel—the make for March amounted to 116,726 tons. The disposal of the iron made was as follows:—57,060 tons were shipped from Middlesbrough; 64,673 tons were consumed locally or sent off by rail; making a total of 121,733 tons. On the 28th of February the total stocks stood at 279,029 tons, and on the 31st of March at 274,022 tons, showing a decrease of 5,007 tons over the month.

MANUFACTURED IRON AND STEEL.—Most of the public works are closed for the holidays, and are not likely to be reopened this week. There is a dulness in both the iron and steel trades, and it is being felt more and more as the season goes on. Few new orders are coming in, and there are fewer inquiries than is usual at this season of the year. Prices remain much the same as usual. Iron ship plates are at £6 12s. 6d.; angles, £6 12s. 6d.; bars, £6 15s. per ton. Steel ship plates, £7 12s. 6d.; angles, £7 12s. 6d.; rails, £5 17s. 6d. per ton, all less the usual discount.

SHIPMENTS OF PIG IRON.—The shipments since the beginning of April have been very good, averaging upwards of 4,000 tons daily. As shippers prefer warrants, they are drawing from the public stores heavily. Connal's stores have probably never before been so much run upon. The shipments, however, are not yet up those of this time last year.

SUNDERLAND, 9TH APRIL, 1890.

SHIPBUILDING AND ENGINEERING.—Work is now being resumed after the Easter holidays. While there is still a time of general activity in store for these industries, there is a growing feeling that there will soon be comparative quietude. Possibly the output for the year 1890 may exceed that of 1889 at this port; at all events, the results of the first quarter point in that direction, twenty vessels of 45,881 tons having been launched up to March 31st, 1890, as against the same number of vessels of 41,511 tons in the corresponding period of last year. But new contracts are not booked in anything like the same proportion that vessels are completed; in fact, it is doubtful if two orders have been booked on the river during the quarter. Amongst the noteworthy orders in course of execution is one for a mail and passenger steamer for a French company at Marseilles, to carry 1,400 to 1,500 emigrants, besides first and second class passengers. This vessel is being built by the Sunderland Shipbuilding Company, Limited, and is to attain a speed of 14½ knots.

SHIPPING.—The prospects of the freight market are far from bright. Vessels are being sent out to the United States in ballast owing to the unremunerative character of outward rates. Homewards the market is firm, but in all other quarters, as compared with the corresponding period of last year, there is a falling off; this, combined with heavier working expenses owing to dearer bunker coals, is seriously affecting shipping. Possibly a good harvest in South Russia will yet cause a boom in the freight market, but as yet rates from the Black Sea are far from satisfactory. The demand for coals does not now appear to be so great, owing to the mild winter. During the past week 72,421 tons of coal were shipped as against 70,355 tons, 68,540 tons, 84,257 tons, 65,231 tons, and 78,647 tons in the immediately preceding weeks; 48,126 tons were shipped coastwise, and 24,235 tons to foreign ports. Other coastwise shipments included 250 tons of patent fuel, 170 tons of cement, 135 tons of bricks, 130 tons of steel plates, 76 tons of lime, 53 tons of crystals, and 15,000 dozen glass bottles. The imports for the week comprised nine cargoes of timber and 42,417 sacks of wheat.

NEWCASTLE, 9TH APRIL, 1890.

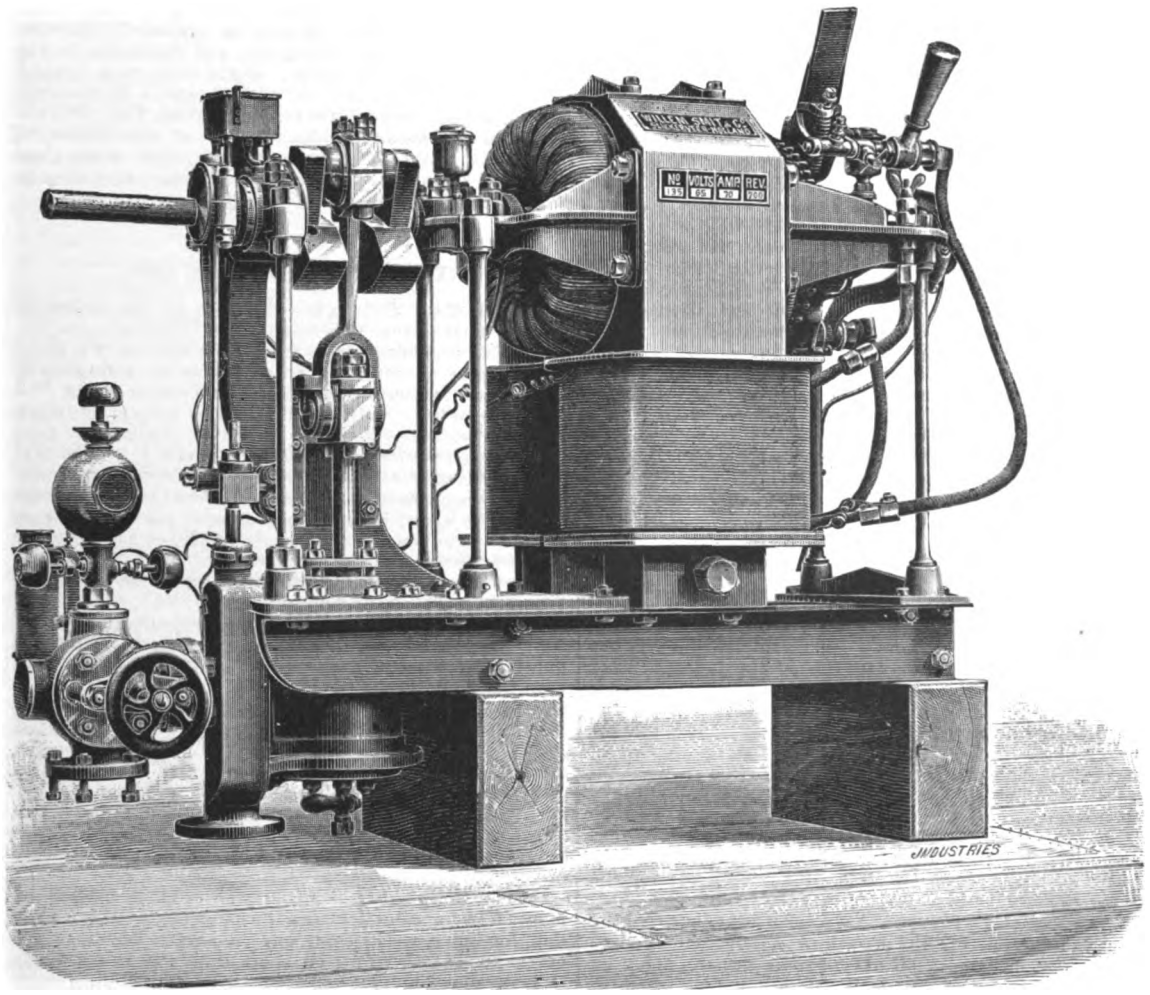
THE EASTER HOLIDAYS.—In most of the industrial establishments work was suspended on Thursday, April 3rd, for the Easter holidays, and a resumption does not take place till to-day or to-morrow. According to an arrangement entered into in connection with the settlement of the "12 o'clock Saturday" question, the holiday periods in future are to be restricted in length, but this arrangement does not come into effect till Whitsuntide, and it is doubtful that even then it will be carried out with strict exactitude. The inconvenience and loss resulting from prolonged holiday periods have frequently been pointed out in *Industries*, and it is to be hoped, now that the employers have come to a definite understanding with the workmen for an abatement of the evil, that they will insist upon the latter fulfilling their part of the compact.

ENGINEERING.—The constructive department of the North Eastern Railway Company at Gateshead is at present unusually busy, and a number of additional hands have been taken on. The principal work in hand consists of a set of ten locomotive engines of a larger and more powerful type than any which have hitherto been constructed for the company's service, and they are designed for the attainment of a higher rate of speed than has yet been attempted. It is estimated that each of these engines, with its tender and accessories complete, will weigh about 80 tons. It may be stated here that the constructive establishments of the North Eastern Railway Company at other centres are also exceedingly busy just now.

GLASSWORKS AND POTTERIES.—In these classes of manufacturing establishments business has been somewhat dull for some weeks past, and in several instances the operatives have been put on short time. It is not likely that any considerable change for the better will take place before Midsummer, when orders in connection with the fruit-preserving trade may be looked for.

THE COAL TRADE.—The mild weather which has lately been experienced has caused a lessened demand for household coals, and the falling off has not been compensated for by any improvement in the demand for other qualities. The pits throughout the district are laid in during the holiday period, and the stoppage will, of course, cause a diminution of stocks. The shipments of coal and coke at Tyne Dock during the week ending the 5th inst. amounted to 88,155 tons, being a decrease as compared with the shipments for the corresponding week last year of 4,644 tons.

THE CARRIAGE TAX.—It is gratifying to hear that the Coachmakers' Company have recognised the efforts which were successfully made by Mr. John Philipson, the well-known coachbuilder, of Newcastle, to obtain a modification of the carriage tax. The other day they sent him an official address thanking him for his labours. It appears that Mr. Philipson spent nearly £500 in prosecuting the agitation for an all-round 15s. tax for public carriages, great and small, and a testimonial is being raised to defray these expenses. Mr. E. Rogers, carriage manufacturer, Bristol, is treasurer of the fund.



DUNDEE, 9TH APRIL, 1890.

JUTE AND FLAX TRADES.—Business has been interrupted owing to the holidays. There has been little change in the position of the staple industries of the district during the past fortnight. Jute of good quality in dock lots is selling at high prices, but there is hardly anything doing on contract. Jute yarns are inactive, but prices of fine spins are decidedly firm. There is a fair demand for jute goods, and manufacturers being well employed quotations are maintained. Very little business is passing in flax, either on spot or for shipment. There is more inquiry for flax yarns. The home demand for linens is good, inquiries coming in pretty freely. On shipping account there is as yet little movement. The proposed changes in the United States tariff are attracting attention here, and it is feared that if the new rates are adopted the local trade will be injuriously affected. The most important change is the proposed removal of the 20 per cent. *ad valorem* duty on raw jute. It is believed that the result of this change would be to stimulate the jute manufacturers of the States. Should the proposed change be made we shall probably have a demand from our manufacturers for the imposition of an export duty on jute. The removal of the duty on the raw material will, if the jute interest on the other side has its way, be accompanied by an increase in the duty on manufactured articles, both linens and hessians.

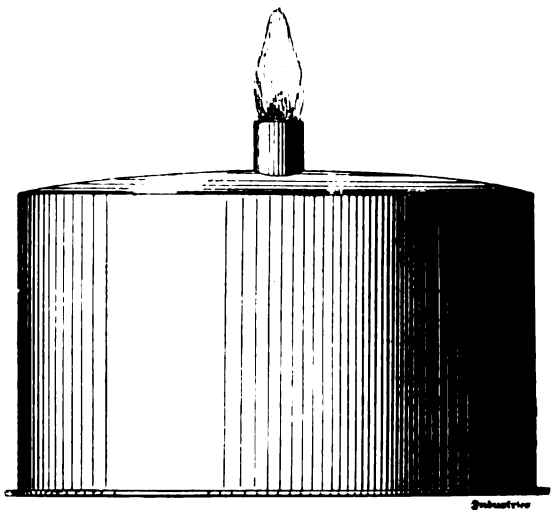
COMBINED ENGINE AND DYNAMO.

CONSTRUCTED BY MESSRS. WILLEM SMIT & CO., SLIKKERVEER, HOLLAND.

BREAKDOWN OF THE "CITY OF PARIS."

THE accident which has befallen the "City of Paris" is a matter which requires the careful attention of all interested in shipbuilding and naval architecture, for, however important it may be to the owners or the builders of the ship, it is of much greater importance to the travelling and trading public, and it should be used to extract lessons for guidance in the future. No doubt a complete investigation will be made into the whole circumstances of the case, but, in the meantime, it may be well to note some of the points in connection with it. As to the facts, so far as they are known, we have, in the first place, the official report of the captain, which we gave in our last week's issue. His short report has been amplified by letters from passengers, but these contain little information which will be of use in arriving at a conclusion as to the cause of the accident, but they all testify to the excellent behaviour of the crew and all on board. Fortunately the weather was fine, and by hard work the crew and passengers were able to keep the water under.

The cause of the accident must in the meantime be a matter of speculation. What occurred to marine engineers was that it was due to water having collected in the cylinders, and to the piston having come down as upon a solid block upon the confined liquid, and smashed out the bottom of the cylinder, and caused damage to the side of the ship by breaking injection and water pipe connection, and, at the same time, injuring the bulkhead. The examination which was made of the ship after its arrival at Queenstown proved that the inflow of water was altogether due to the destruction of the injection pipes. The divers found that it was quite feasible to plug these, and a large quantity of the water was pumped out, and the ship was soon at her usual draught. The port engine was found to be in good working order.



Whatever doubt there may be as to the cause of the accident, there can be none as to what saved the ship from sinking almost instantly. It had fourteen bulkheads, which thus divided it into fifteen portions, any one of which might be filled with water, while the other compartments would be perfectly safe so long as the bulkheads remained intact. When the engines gave way the longitudinal bulkhead between the engine rooms was damaged, so that both sets of engines were disabled, but notwithstanding this the ship drifted about for three days with more than 2,000 tons of water in these two compartments before help came to her. The first lesson, then, which the disaster teaches is the necessity of having a sufficient number of sufficiently strong bulkheads, both longitudinal and transverse, in every ocean-going passenger steamer, as to practically make her unsinkable. Lloyd's Register Committee have done good service in directing more attention to bulkheads, both as regards number and strength, and especially to those bounding the engine spaces. The fact that the longitudinal bulkhead between the engine rooms gave way practically nullified, as regards safety, the advantages of having duplicate sets of engines. If one set could have been worked, the ship might have been safely brought into harbour without assistance of any kind. It is quite evident, now that the accident has directed attention to the subject of bulkheads, that regulations will be made more stringent regarding them. Mr. Plimsoll has taken up the matter, and he points out that watertight compartments in iron ships were once made compulsory by various Acts passed between 1846 and 1854, and that in 1862 all this legislation was swept away secretly and silently, not a word of explanation being given to the House of Commons to show what was being done. But he remarks that, fortunately for the nation, Lloyd's Register Committee refused classification to any ship the owner of which availed himself of this "dreadful liberty" to dispense with bulkheads, and the consequence is that the greater proportion of our iron ships have now four, five, or six bulkheads, according to their length.

The fact that the divers found that the holes could be plugged up seems to prove the advisability of such large ships as the "City of Paris" carrying a diver with proper diving dress, who could ascertain the actual state of the case, and might often save, not only anxiety, but expense.

Admiral Elliot writes to the *Times* to point out that the accident to the "City of Paris" brings into prominence the decision lately arrived at by the Board of Admiralty—to abandon entirely sail motive power, even for war vessels intended for long voyages in distant seas. He says it is almost a certainty that if the accident to the "City of Paris" had occurred in the Southern Atlantic or Pacific or Indian Ocean, and the ship had been drifted by currents out of the beaten track of steamers and in unfavourable weather, and possibly distant 1,000 or 2,000 miles, instead of only 200, from the land, she would never have been heard of; whereas a very moderate supply of sail power would have enabled her, especially in the locality of prevalent winds, to keep in the track of vessels, and probably reach the land. Admiral Elliot thinks that sail motive power, as an auxiliary to steam, might advantageously be abandoned in battle-ships and cruisers intended for European waters; but for distant voyages on the wide ocean the decision arrived at is wanting in precaution, and it is to be hoped that the recent disaster may cause more prudent counsels to prevail at Whitehall. The same remarks also apply to merchant ships. The Board of Trade is now directing special attention to life-saving appliances, such as life boats and belts; and while this is quite proper, it ought also to insist, as far as it can, on arrangements being made which would make these almost entirely unnecessary.

THE "DEVONSHIRE" EVERLASTING CANDLE.

THE accompanying illustration represents one form of a new, ingenious, and inexpensive lamp which is being introduced by Mr. Devonshire, of 243, Pentonville Road, London, N. These lamps are suitable for night lights, fire lighters, portable stoves for cooking purposes for picnic parties, &c. They can be made in any form with any number of burners, whilst for simplicity of construction, entire absence of movable parts, and freedom from danger, they would certainly appear to supply a long-felt want. Each lamp consists of an outer casing

of metal, glass, or other material, with a perforated bottom, and almost completely filled with a porous earthy material, which the inventor terms "Egyptian clay," which absorbs the oil, and above this is placed an indestructible wick composed of a mixture of slag wool and asbestos fibre. To charge the lamp it is merely necessary to place it on a saucer or plate containing oil, which will be absorbed by the porous material inside. This charge will be sufficient, we are informed, to last a lamp of the same size as our illustration for sixteen hours. It is claimed that these lamps are much cheaper than composite candles, while giving an equal light.

THE SMIT COMBINED ENGINE AND DYNAMO.

MESSRS. SMIT, of Slikkerveer, Holland, have brought out a neat combination engine and dynamo lighting an arc light projector at sea. It is designed with a view of having as little weight as possible. The output is 65 volts and 70 amperes, as required for the Dutch Navy's torpedo boat "Cerberus." In order to reduce the weight to the lowest possible limit, as demanded by the naval authorities, Messrs. Smit have used an open engine instead of the closed-in type, and thus have sacrificed efficiency, durability, and freedom from breakdown. The armature is Gramme wound with 3·5mm. wire. The speed is 450 revolutions per minute, and is controlled by an electromagnetic governor interposed in the shunt circuit.

The engine has 4in. cylinder, by 5in. stroke, and works with 100lb. to 150lb. pressure of steam. The engine and dynamo together weigh 840lb., and the 20in. projector to match weighs 520lb., or 1,360lb. total weight. The outside dimensions are 3ft. 9in. long, 2ft. 6in. high, and 1ft. 5½in. broad.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 11TH APRIL, 1890.

THE BERLIN LABOUR CONFERENCE.

THE Congress, unique in its kind, convened by the German Emperor to deliberate concerning industrial reforms, has completed its work and delivered its report. We have described this Conference as unique, for never before have representatives of the peoples of Europe been called together in council by Imperial authority to discuss other than political questions. This new departure is, therefore, a remarkable event in the history of the present age. That it will be a memorable event—a landmark in the development of industry in the nineteenth century—none can doubt; for though its direct consequences may be of small importance, indirectly it will influence in a large degree the future of industrial life. Its chief claim to consideration at the present time lies in its being the beginning of a system of international control of labour which seems to have become a necessity of the times in which we live. We do not believe it practicable that any large amount of such control can ever be exercised. But the conditions of trade have become of such a nature that, to keep competition within reasonable limits, the labour question must be considered and provided for in wider relations than those of merely local convenience. Baron von Berlepsch speaks of the achievements of the Congress with wise moderation. He claims only to have found "a basis on which the thought of affording the working classes better protection, greater security for their material, physical, moral, and intellectual powers, may live on and be further developed." This basis is practically the state of things now prevailing in this country, and the development is, in reality, nothing more than the approximation of Continental to English practice. For what are the Resolutions but recommendations to adopt as a uniform system the laws and regulations by which English industrial life is now governed? This result would have been arrived at in a few years without the Conference. It was brought about in this country without any such official aids, and events abroad have for some time past been visibly tending in the same direction. But the Conference has hastened the current of events, and made that possible within the present century which otherwise might have required a much longer time for its accomplishment. Public attention has been directed thereby to the question, and public opinion has been influenced in its favour. The working classes have been greatly encouraged to press their claims for immediate satisfaction, and a wider scope has been given to their aspirations. And the Socialists, though in some respects checkmated thereby, have acquired fresh strength from the acknowledgment of the justice of some of their pretensions. These effects must all tend to promote the movement of reform now in progress.

Among the recommendations of the Conference a prominent place is given to the Council of Arbitration. This remedy for strikes—the only efficient remedy, it seems to us—has already been discussed in these columns. Our view is considerably at variance with that propounded in the official report of the proceedings at Berlin, for in the latter the Council is to be composed solely of employers and employed. We believe the presence of a third and disinterested party essential to the success of such an undertaking. This third party might be one of the law officers of the Crown or his representative. Moreover, the Conference would make the Council optional, a provision which, in our opinion, would leave matters pretty much as they now are. What is wanted is a standing Council, a properly constituted Court of Appeal, always ready to deal with every question as it arises, and invested with authority to enforce its decisions. We should have liked to see such a Council recommended by the Berlin Congress. What it proposes is but a half measure, inadequate to the requirements of the case. Another recommendation, that of periodical International Labour Conferences, is open to the charge of being impracticable. There may be certain conjunctures of circumstances when, as now, it may be desirable to convene the representatives of several nations for the purpose of conferring together on some question of which the solution cannot otherwise be arrived at. But such opportunities must necessarily be of rare occurrence. On what basis could such Conferences meet? What is trade but incessant industrial war? Competition is but another name for combat. When competition has become so keen that both parties are being ruined by the struggle, the time will have arrived for some mutual agreement to mitigate the sufferings of the combatants. Till then it is vain to hope for international treaties to regulate labour. Will, for example, the men of a district, in which the conditions of a manufacture are specially favourable to cheap production or cheap distribution of the produce, consent to nullify their advantages for the good of another district less fortunately situate? Yet it is something of this nature which is asked for, when the working men of one country are called upon to regulate their affairs in conformity with those prevailing in another. And unless something of this kind be demanded, of what use will the periodical International Conference be? We fear that, except in the particular case we have mentioned, the international regulation of labour, whether by Trades Unions or by Governments, is but a dream.

What will be the practical consequences of the Berlin Conference? That its recommendations will for the most part be carried into effect without unnecessary delay may be safely assumed. First, because they are nothing more than the objects for which the toiling classes, who are rapidly acquiring political power, have been striving. Next, because the maintenance of the existing order of things gives strength to the Socialist party in the State. And lastly, because each and all of the Governments who were represented at Berlin will feel bound to make some manifestation of good-will by giving effect to the resolutions to which they have openly subscribed. For ourselves we can afford to stand quietly by, since the Resolutions do not apply in our case. When all the recommendations have been adopted by our foreign rivals in trade, we shall not have been left behind in any particular. But the reform undertaken by our neighbours will greatly affect our position in the industrial world. We have suffered from foreign competition because we have hitherto been alone in the work of improving the material condition of the working classes. The price paid for the industrial legislation of recent years has been an increased cost of production, which increase has heavily handicapped us in the race of com-

Digitized by Google

petition. The general adoption of the measures recommended by the Conference will change all that by putting all parties on an equality in those matters. By adding thus largely to the cost of production abroad, British commerce will be relieved and British industry stimulated. The project of the German Emperor inaugurates, therefore, a period of returning prosperity to this country. So much at least we may hope for. There is but one thing which could prevent its attainment, namely, fresh and commensurate demands on the part of the British workman. Here is an opportunity for the trades unions to give proof of practical wisdom. By manifesting and recommending a spirit of moderation at times when circumstances are favourable to fresh acquisitions they will earn the gratitude of all classes of the community. Only by such self-denial in moments of prosperity can the working men of this country profit to the full by the altered state of industry abroad brought about or hastened by the Berlin Conference.

THE ADMIRALTY DYNAMO SPECIFICATIONS.

THERE has been considerable discontent among dynamo makers on the subject of the Admiralty specifications, the temperature clause being generally the centre round which differences arise.

The method of testing the temperature seems to be very unsatisfactory. It is specified that, after running for six hours at full load, "no accessible part of the armature or magnets should have a temperature of more than 20° Fahr. above the temperature of the dynamo room." This temperature is taken at the end of one minute after stopping. In many, especially of the more recent specifications, 30° Fahr. is substituted for 20° Fahr. The question that has always puzzled the contractors is: How is the temperature taken? It seems that it is taken by laying a thermometer on the armature or field magnets and seeing what reading it gives. But it is clear that the apparent temperature, as given by a thermometer under these circumstances, has no very definite relation to the real temperature of the outside of the armature. The dynamo is allowed to rise in temperature to 70° Fahr. after stopping—that is to say, there may be a sort of store of heat in the armature. Before a machine is stopped after six hours' run at full load the armature and all parts of it have come to their final temperature—that is to say, the heat dissipated is exactly equal to the heat developed. For the sake of simplicity we will assume that the armature is a drum with no internal ventilation. As a matter of fact, this is the type generally used. In that case all the heat is dissipated from the outside of the armature by radiation, conduction, and convection. The last two are intimately connected and may be taken together, and account for the greater part of the heat. As the heat is all developed in the armature, and must find its way to the outside there must be a difference of temperature between the inside and outside. If the parts where the heat is generated are covered in with insulation, which is a bad conductor of heat, the conductors will be at a much higher temperature than the surface of the armature. Only a small amount of heat is generated in the core itself, so there will be little flow of heat from the core through the insulation into the conductors and thence to the surface; the core will thus be only slightly hotter than the conductors themselves. On first starting, the core is colder and is heated partly by the armature conductors and partly by its own loss by hysteresis, but, though its capacity for heat is large, because of its large mass, it will eventually become somewhat hotter than the conductors.

As the amount of heat which will penetrate the outside insulation in a second depends on the heat conductivity of the insulation and the difference of temperature, it follows that if the insulation is a very bad conductor of heat the difference of temperature between the conductors and the surface of the insulation of the armature will be great. The less the outside of the armature is lagged, therefore, the lower will be the temperature of the conductors for a given total loss of heat per second in the armature. As far as heating is concerned, therefore, the less lagging the better.

Let us now consider what happens on stopping after the six hours' run. The facilities for the escape of heat from the surface of the armature are enormously reduced, because there are now no draughts caused by the rotation of the armature. The generation of heat in the armature is also stopped, but the core acts as a store. If all escape of heat from the surface were prevented, the conductors would rise to the same temperature as the core—that is to say, a little higher than they were before stopping. The surface of the armature would also rise to the same temperature. If there is some dissipation of heat, however, the surface never gets so hot, and the difference in temperature between the surface and the conductor may be considerable.

If a thermometer is now applied for a minute. and covered in, say, by a bit of waste, the capacity for heat of the thermometer is, as pointed out by Mr. Willans, very considerable in comparison with the rate at which the heat can flow into it; the result is that the thermometer does not measure the temperature at all, even of the insulation on the immediate surface, much less of the conductor under it.

Suppose now the thermometer with the bit of waste is left for, say, half an hour, its temperature will rise nearly to the temperature of the conductors at that time. It will not rise quite so high, because the loss that still takes place through the waste is not insignificant in comparison with the supply of heat through the insulation of the conductors. Suppose the thermometer at this time shows its maximum reading of a rise of 70° Fahr. above the atmosphere, the temperature of the conductors underneath it must be still greater, by how much cannot be definitely stated. The conductors at the maximum reading are then more than 70° Fahr. above the atmosphere; but they have been cooling slowly for some fifteen or thirty minutes, so that at the instant of stopping they must have been considerably more than 70° Fahr. above the atmosphere. It might be urged that at the instant of stopping they were cool, but the core was hot. This reasoning will not hold, however, for there is so little heat generated in the core itself that it cannot be much above the temperature of the conductors. It must also be remembered that during the fifteen or thirty minutes the conductors have been getting rid of heat through the insulation to the surface, and there is a layer of insulation between the core and the conductors. So with the very slight difference of temperature between the core and the conductors at the instant of stopping, the conductors would get rid of heat much quicker through the outside insulation, which has a large difference of temperature on its sides, than the core could supply heat through the core insulation with a small difference of temperature.

Suppose now that the external insulation or lagging were taken off and the dynamo run again for six hours at full load. The same amount of heat would be generated per second, so, as the radiation, convection, and conduction from the surface remain as before, the same external or surface temperature would be reached, and this would now be the temperature of the copper itself. The core would be at a slightly higher temperature. On stopping and placing the thermometer on the copper with a piece of waste over it as before, the thermometer bulb would absorb more heat than before in a minute, so that at the end of the first minute the temperature, as taken by the Admiralty, would be higher than before; simply because the copper could now supply heat quickly to the thermometer bulb, as there is little or no insulation to stop the flow.

If the thermometer is left on, it might rise a little more, though the temperature of the copper will be falling gradually, as in the first case; but the thermometer can never rise to the temperature shown in the first case because the copper and core are so much cooler to begin with. The Admiralty test thus shows a higher temperature for the cooler machine, as far as the 20° or 30° test is concerned; and if, as we understand, most importance is attached to this test, the Admiralty are doing their best to select bad dynamos. The one minute test is, as Mr. Willans pointed out at the Institution of Electrical Engineers, simply an absurd method of putting a premium on lagging dynamos in so as to supply little heat to a thermometer bulb while the temperature of the conductors is high.

The temperature of the core does not matter, what is really important is the temperature of the insulation, on which the life of the machine depends. The insulation which is important is in contact with the copper conductors, so all that is required is to see that the temperature of the conductors is not too high. This cannot be found by leaving thermometers about on the armature, but can be determined with the greatest accuracy by measuring the rise of resistance of the conductors. There are so many simple ways of taking the resistance, even of a short thick bar, that it is not necessary to discuss them. Another curious regulation in the specification is that the rise of resistance of 20° or 30° Fahr. only concerns the accessible parts of the dynamo. Apparently the inaccessible parts do not matter. This is strange, because the accessible parts are the parts which are easy to repair; and there is no reason why the parts which cannot be got at should be allowed to come to any temperatures they like. Many makers of drum armatures close the ends in such way that the rise of temperature there is very great, an this is a frequent cause of breakdowns.

As to the highest temperature admissible, we think the Admiralty place the limit not too low, but far too high. As already explained, if the maximum rise of temperature measured in their way is 70° Fahr., it is really probably much, very much, more; but even if the conductors themselves only rise 80° Fahr., this means, in a stoke hole at 120° Fahr., that the conductors are at 200° Fahr., or nearly the temperature of boiling water! Ordinary dynamos in this country are made to have a maximum temperature of about 150° Fahr.; in the United States they often allow 200° Fahr. There is no difficulty at all in making machines for Admiralty work which will have a maximum rise not exceeding, say, 40° or 50° Fahr., and still smaller rises can be obtained by making the dynamos very large, and using low current densities.

The point at which insulation will char seems to be a matter of doubt. Most forms of insulation will stand 300° Fahr. for some hours without charring, but a much lower temperature will char them if applied long enough. The question is not at what temperature insulation will become carbonised enough to conduct, as to make it conduct a red heat is necessary, but at what temperature it will become brittle and mechanically weak. The cleading on a locomotive lasts for years without being thoroughly charred, but it is converted into a sort of tinder without any mechanical strength in a very short time.

Though armatures with bare copper conductors keep cooler, there is more chance of small particles of metal bridging across and starting short circuits. Apart from this, however, bare copper feels hotter to the hand, and most people try to judge temperatures by the feel. A piece of bare copper at a temperature of 120° Fahr. will burn the hand rather unpleasantly, but if it is thickly insulated it will feel comparatively cool. It is a trick perfectly well-known in the trade, when an armature gets rather warm, to lag it in so that it gets hotter than ever, for the average customer will merely feel it with his hand.

Apart from the question of the way temperatures are measured, or supposed to be measured, there is a common idea that a dynamo that gets hot must be less efficient than one that keeps cool. If the machines are the same size, and give the same output, and have the same amount of lagging on the armatures, this is, of course, perfectly true; but if the hot machine gives a larger output, or if it gives the same output and is smaller, it may be more efficient than the cool one. The temperature depends, not only on the power wasted in the armature, but also on the facilities for dissipating the heat. Other things being equal, the small armature has less facilities; so a small machine may easily be hotter than a large one and give the same output at a higher efficiency.

Before leaving the subject of heating, let it be clearly understood that we do not mean to say that the machines made for the Admiralty necessarily run hot; all we say is that the 20° or 30° clause is well calculated to make them do so.

There are very few other points in the specification which have given rise to much trouble. Nothing is said as to whether the machine is to compound accurately at the temperature of the room in which the trial takes place at Portsmouth Dockyard, or in a 120° stoke hole. If they are to be run in a hot stoke hole, resistance should be inserted in the shunt circuit during the Portsmouth test.

There are some curious regulations. A whole paragraph is devoted to details about the commutator dimensions, and another to the brushes. Surely it would be better to leave these matters to the contractors, who, if they know how to make dynamos at all, know how to make commutators and brushes. Stringent rules might, with equal propriety, be given as to the design of the terminals or the shape of the eye-bolt. These regulations only prevent makers using their ordinary patterns for commutators and brushes, and thus give annoyance. The regulation that only 96 per cent. copper should be used might be removed with advantage. No maker would use impure copper, because it costs nearly as much per pound, and a lower current density, and therefore more copper would have to be used. A rule might as well have been inserted to say that a maker must not buy his raw material dear if he can get better stuff cheap. Such a regulation can only make the Admiralty appear in an absurd position in the eyes of the contractors.

Apart from these points there is nothing to be said against the Admiralty dynamo specifications. As many dynamo makers have said, they have done a great deal of good. The direct, coupled engines and dynamos now coming into such extensive use for central station work were worked out to suit Admiralty requirements, and their strictness in passing nothing but the best work has been highly beneficial to the electric lighting industry.

ARCHITECTS' REGISTRATION BILL.

Two years ago the engineering profession was somewhat fluttered, and to a certain extent amused, by the good intentions of some unknown friends, who seemed to think that a special Act of Parliament was required for their protection and that of the public. A Bill was introduced with the innocent title of the "Architects' Registration Bill," but on looking into its provisions it was found to contain a great deal that was of interest to others besides architects. Its preamble stated that, "whereas it was expedient that persons requiring professional aid in architecture, civil engineering, or surveying, should be enabled to distinguish qualified from unqualified practitioners, it was expedient . . . . &c. &c." In short an unknown body of architects took under its protection the whole engineering profession, and drew out most elaborate regulations for its guidance. The odd thing was that the representative institutions named in the Bill disclaimed its paternity, and did all they could to oppose it. The whole thing seemed so utterly ridiculous and pretentious that it collapsed after a very short debate in the House of Commons. This year the Bill has been reintroduced with the same name, but with much more limited provisions, it being entirely confined to architects, and engineers are left in the same position as they were, for which they ought to be profoundly thankful. Engineering is much too big a profession, or rather group of professions, to be taken under the protection of the architects, even if it were desirable to do so. We, of course, are of opinion that every profession or trade should guard the admission to its ranks in such a way as to ensure to the public that those enrolled in them are fairly well qualified for the duties they undertake, and this is now being done to a very considerable extent, and the practice is certain to spread. We would have thought, however, that the architects were less in need of an Act of Parliament than any other profession, because for a good many years past the Royal Institute of British Architects has had an examination for its Associateship which has done much to raise the standard of architectural education throughout the country, and the various local institutions of architects are more careful in the matter of admitting members than the majority of other professions. The question for the architects to consider is: whether by extending and improving their present organisation they could not meet all the wants of the profession and of the public? We are strongly of opinion that they could, and that any Act of Parliament is altogether unnecessary. Let the Royal Institute of British Architects place itself at the head of the movement, and co-operate with the various local institutions throughout the country, and an organisation could be arranged which would be more useful to the profession than anything which is done under the guidance of an Act of Parliament. We are rather curious to observe what steps the architects will take in this matter, and our chief interest in it is the effect which such a precedent would have on other professions and trades more directly connected with the industries with which we are concerned. We think that if they are wise they will organise their own affairs, and develop that spirit of freedom and independence which will do them and their members more good than any amount of Government support or interference.

BOARD OF TRADE RULES ON LIFE SAVING APPLIANCES.

(*Concluded from page* 330.)

VIII. Sailing Ships.

CLASS 1.—*Rules for Sailing Ships carrying Emigrant Passengers subject to all the Provisions of the Passengers Acts.*

Sailing ships of this class shall carry boats in accordance with the following Table, and such boats shall be, as far as practicable, placed under davits with proper appliances for getting them into the water, to the satisfaction of the Board of Trade officer, such of these boats as are not placed under davits being so carried that they can also be readily got into the water, to the satisfaction of the Board of Trade officer, but no sailing ship of this class shall be required to carry more boats than will furnish accommodation for all persons on board.

If the boats so carried do not furnish sufficient accommodation for all persons on board, then additional wood, metal, collapsible or other boats of approved description (whether placed under davits or otherwise), or approved lite rafts shall be carried.

Such additional boats or rafts shall be of at least such carrying capacity that they and the boats required to be placed under davits provide together, in the aggregate, double the minimum cubic contents required by column 3 of the following table.

All such additional boats or rafts shall be placed as conveniently for being available as the ship's arrangements admit of, having regard to the avoidance of undue encumbrance of the deck, and to the safety of the ship for her voyage.

When sailing ships are divided into efficient water-tight compartments so that with any two of them in free communication with the sea the vessel will remain afloat in moderate weather, they shall only be required to carry additional boats or life rafts of one-half of the capacity required by preceding paragraph.

Sailing ships of this class shall carry approved life belts or other similar approved articles of equal buoyancy, suitable for being worn on the person, so that there may be at least one for each person on board; and there shall also be one approved life buoy for each boat of wood or metal.

CLASS 2.—*Rules for Foreign-going Sailing Ships carrying Passengers, but not subject to all the Provisions of the Passengers Acts.*

Sailing ships of this class shall be subject to the same requirements as those in Class 1.

CLASS 3.—*Rules for Foreign-going Sailing Ships not carrying Passengers.*

Sailing ships of this class shall carry boats in accordance with the table provided for Class 1, and in addition thereto one good serviceable boat properly constructed of wood or metal. Such boat shall be, as far as practicable, placed under davits, with proper appliances for getting them into the water to the satisfaction of the Board of Trade officer; such boats as are not placed under davits being so carried that they also can readily be got into the water to the satisfaction of the Board of Trade officer.

Sailing ships of this class shall carry approved life belts as required for sailing ships of Class 1., and also one approved life buoy for each boat of wood or metal.

CLASS 4.—*Rules for Sailing Ships engaged within the Home Trade Limits—that is to say, between Places in the United Kingdom and Ports in Europe between the River Elbe and Brest, but not carrying Passengers.*

Sailing ships of this class shall carry a boat or boats of wood or metal at least sufficient for all persons on board, and in such a position as to be readily got into the water to the satisfaction of the Board of Trade officer. Each boat shall be provided with one gallon of vegetable or animal oil, in a vessel of an approved pattern, for distribution on the water during rough weather.

They shall carry an approved life belt for each person on board.

They shall carry at least two approved life buoys.

TABLE FOR SAILING SHIPS OF CLASS 1.

Gross Tonnage. 1.	Minimum Number of Boats to be placed under Davits. 2.	Total Minimum Cubic Contents of Boats to be placed under Davits. L. × B. × D × ·6. 3.

Letters to the Editor.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

SIR,—Your correspondent "Car" is mistaken in supposing that a special new roadway is required to work our patent low-pressure compressed air tramcar system. Our system can be applied to any existing roadway, of any gauge, without any alteration whatever. All that is necessary as regards the road is to lay the air main under the footway, with branches across to the valve boxes, which are fixed beside the rails at intervals of from a quarter of a mile to a mile apart, according to the nature of the gradients.

The car was, as your correspondent states, "only an experimental one." Nevertheless, the results obtained from it, even in its imperfect state, show a decided advantage over any other system of traction. The above table gives particulars of cost and working expenses for four lines for which we have sent in tenders, and is based on the actual results obtained from this experimental car. We have thought it safer to base our calculations upon what we actually know and can rely upon, as confirmed by the experiments of Professor Unwin and Mr. D. K. Clark, than to make any allowance for anticipated improvements. The figures are quite good enough as they are, and we prefer to leave the improvement that may be counted upon in the actual results with the specially constructed car to speak for itself.

From this table your correspondent will see how very much the first cost and working expenses vary with the conditions of each case, and how impossible it is to lay down any general rule. We have not included buildings in the capital cost, as the existing buildings in each case were to be utilised, and we have also omitted from the working expenses the directors' fees and general management charges, as these follow no fixed rule. These items, however, are easily estimated according to the conditions of each case. In No. 3 case, the cost of running is given as 4¼d., which covers all expenses included in the ascertained cost of 6⅛d. per car mile by the steam locomotives, at present used on this line.

We cannot give a comparison with electric traction, as we find it impossible to get at any reliable data, especially as to performance on steep gradients. We can only point out that the Brussels Tramway Company have abandoned electric traction after four years of patient effort, and a loss of £1,144 as compared with horse traction, seeing no prospect of making it pay, even after making every allowance for all possible improvements. We believe this is the only case in which the system is worked by the tramway company, and not the electric company, and where, consequently, the actual results are obtainable.

The letter of "A. W." refers to the Mekarski tramcar system, in which the air is compressed to about four times the pressure required for our cars. All the advantages referred to by "A. W." apply to our system, with the additional advantages that our cars are much lighter, having no elaborate heating apparatus, require much less power owing to the much lower pressure used, —the power required to compress the air being, for a level line, 4,900,000 ft. lbs. per car mile on Mekarski's system, against 3,800,000 ft. lbs. on our system. As regards liability to explosion, Mekarski has a body of water in his "hot-pots" heated to a temperature of 320° Fahr., which, in case of a rupture of the receiver, would produce an explosion as destructive as any boiler explosion.

We have nothing of that kind in our cars, and only one-fourth of the air pressure, with corresponding increased safety.

Yours, &c.,

HUGHES & LANCASTER.

City Road, Chester, April 9th, 1890.

THE INSTITUTE OF MARINE ENGINEERS.

THE annual general meeting of the Institute was held in the Langthorne Rooms, Broadway, Stratford, on the 29th ult., when the secretary read his report and balance sheets. He reviewed the history of the Institute during the first year of its existence, and briefly referred to the initial work of the organising committee. The balance sheet showed an eminently satisfactory condition of the finances, the receipts being £499 10s., and the expenditure £302 18s. 8d. The voting for officers for the ensuing year resulted as follows:—President, Mr. G. W. Manuel; secretary, Mr. Jas. Adamson; treasurer, Mr. R. Leslie.

After a number of congratulatory speeches, Mr. G. W.

Digitized by Google

Manuel, the new President, gave his opening address, in which he said that he looked back with no small surprise on the amount of work which had been accomplished during the past year. The amount of vitality which was evidently in the members was very great, and therefore he augured well for the second year upon which the Institute had entered. He pressed home upon all the necessity of thinking out the various questions connected with marine engines and boilers, and the various machines now fitted in the new steamers for electric lighting, refrigeration, &c. The Institute would become a power in the land for bringing forward the necessity of marine engineers having a higher training before they entered upon duties in the engine rooms of steamers. He pointed out that the duties of engineers would now consist more and more of watching closely the possibilities of increasing the efficiency of the machinery placed in their care.

Mr. Manuel closed by giving the following data showing the progress made during fifty years in the steamers of the Peninsular and Oriental Steam Navigation Company:—

Year.	Ship's Name.	Gross Tonnage.	I.H.P.	Speed in Knots.	Steam Pressure per sq. in.	Description of Engines.
1837	Iberia	516	180	8	7	Paddle.
1852	Indus	1,950	1,367	10 to 11	12	Paddle oscil.
1867	Hindostan	3,113	3,194	12	30	Screw horiz.
1882	Ballaarat	4,752	4,500	13	90	Comp. inver.
1887	Oceana	6,000	7,000	15·7	150	Triple expn.

Mr. H. E. Lester and Mr. R. Leslie then addressed the meeting on the subject of erecting a building for the Institute, to enable the plans which had been laid down by the Council being carried into effect—class and recreation rooms, lecture hall, and rooms in which young engineers, strangers in port, could find accommodation at reasonable rates. It was stated that a sum of not less than £10,000 would be required. Mr. Lester offered to start the building fund by a donation of £10, and £10 more for the purpose of convening a meeting at which the claims of the Institute could be laid before an influential audience.

Several other gentlemen immediately promised other handsome sums, and it is quite probable that the objects of the promoters will be gained.

A meeting of the Institute was held on the 1st inst., when the adjourned discussion on the "Friction of Screw-Propelling Engines" was resumed. Mr. Brett also read a short paper in extension of his original paper with special reference to experiments on friction and the best system of lubrication. An interesting discussion ensued.

THE GIRARD HYDRAULIC RAILWAY.

In *Industries*, of the 23rd August last, we gave a general account of this invention, which has excited so much interest in this country and in America. As it would appear from the paper recently read on this railway before the Society of Arts that a certain interest is still taken in it, we now proceed to complete our description and to illustrate such further details as are necessary to understand the working. Those of our readers who are interested in the historical development of the details we may refer to Girard's voluminous and profusely illustrated English specification No. 2506, 1889. Here will be found a number of ingenious mechanical contrivances, most of which have been very much simplified by M. Charles Armand Athanase Barre, in the railway lately at work on the Esplanade des Invalides.

The shoes which carry the carriages are shown in *Industries*, Vol. VII., p. 176, and are supported by a thin film of water about half a millimetre in thickness. M. Girard's first shoes were flat plates, and he proposed to support them by means of a film of compressed air, but this was at once found to be impracticable. Even with the latest form of shoe the waste of water is very great. The pressure is obtained by carrying on the tender vessels charged with compressed air. These will only carry sufficient air to compress water enough to carry the train about 1,800 yards, and require to be recharged after travelling this distance. For longer journeys, an engine and boiler, with pumps and apparatus for compressing the air, must be carried on the tender, the water being taken up from between the rails, as is now done by express trains in this country. This seems to be a very serious objection, since the weight of the engine and the accessories will be so great as to require an enormous pressure to raise them from the rails, and so neutralise the chief advantage of the system, which is that the carriages and apparatus may be very light, and no practical traction resistance felt.

The construction of the rail requires careful consideration so as to obtain anything approaching the required efficiency. In the trials with his slide at La Jonchère Girard did not pay particular attention to the difference in level of the rails, since he attributed to his slide the entire friction which he found at the several points, such as at the joints of the rails; he, therefore, never attempted any special system of joining the rails with the object of avoiding such differences of level, although methods of joining the rails otherwise ingenious are given in his English specification just referred to. For anything approaching efficiency the rails must have perfectly true surfaces, without differences of level at the points of junction, and they must be free to expand and contract. Many forms have been tried, but the latest and most satisfactory form is shown in Figs. 1, 2, and 3. With this system of rail it is found that the differences of level which may occur are not capable of reaching the normal thickness of the layer of water compressed between the shoes and the tops of the rails, the result being that the highest efficiency resulting from the form of slide is realised. The rails rest on wooden sleepers, and may be of cast iron or steel. They are about 10ft. long. They are planed on the top and sides, and are bolted down to the sleepers by means of the lugs A. The level is preserved as follows: Lugs B are cast on to the ends of each rail and are truly bored. Pins C are inserted and held in position by a small cotter. In the end of each rail is cut a curved groove E F, in which is placed a strip of indiarubber, which is compressed between the two rails, but retains sufficient elasticity to allow of the expansion of the rails.

The high-pressure water main, which runs along the whole length of the line, carries at short intervals injectors, which throw the water against the turbines under the carriages, and thus propel the train. These we shall now describe, as the construction is very ingenious, and is one of the main features of the invention. Fig. 8 shows a vertical section of one of these injectors, Fig. 9 is a plan, and Fig. 7 shows an end elevation partly in section. The high-pressure water from the main is conducted into the chamber G, whence it flows on the opening of the valve H along the pipe J, through the nozzle K, against the blades of the turbines under the carriage. The opening and closing of the valve H is the only difficulty in the arrangement, as it is under great pressure and is liable to severe shocks. The valve rod L, which carries at one end the valve H, carries at the other end a piston M, which works in a cylinder N. This piston has a larger area than the valve H. Water at high pressure can be admitted to the right hand side of this piston by means of the pipe O, the cock P, and the pipe Q. The left hand side of the piston is open to the air, and is acted on by a spring R, which helps to close the valve. When the guide on the carriage opens the cock P by moving the tappet, water flows along the pipes O and Q, and moves the piston outwards, opening the valve H. When the cock is closed the pressure is removed from the back of the piston, and the spring R, aided by the pressure, closes the valve H. It will be understood that when the pressure is taken off the water will escape along the pipe Q, and through the cock P to the waste pipe, the escaping water acting as a hydraulic brake and tending to prevent shocks. But this in itself was found to be insufficient, and a disc was provided on the inside of the piston, which comes into contact with a ring S as the valve approaches its seat, and thus by the friction reducing the shock. It is claimed for the improved injector that it is not affected by frost, but the only reason for this claim appears to be the fact that an arrangement is provided for emptying the pipe when not in use. In M. Girard's injector a hole was made near the valve H from which the water escaped when the injector was not in use, but by this arrangement much water was lost in the working, as a large quantity of high-pressure water escaped during the time the valve H was open. M. Barre designed the arrangement shown in Figs. 7 and 8, by which the high-pressure water is not allowed to escape, and by which he claims that he obtains greater economy. On a horizontal track there will be rarely more than a single injector in communication with the turbine of the train, and the economy is not very great, but on an incline where there are always several and even a considerable number of injectors open at the same time the saving of water will amount to as much as 6 per cent. The action is as follows:—When the valve H is closed water is admitted from the chamber G by a pipe T through the cock U and pipe V to the cylinder W, and this opens a valve X in the pipe J, which allows the water to escape. When the valve H is opened the levers Y Z move the plug of the cock U, and, the pressure being removed from the piston in the cylinder W, the spring closes the valve X, and thus no water is wasted. In the most recent injectors a still simpler appliance is used. It consists of a valve A^1 placed underneath J. When the valve H is closed a spring keeps open the valve A^1, and the water is allowed to escape from the pipe J. When the valve H opens the pressure of the water closes the valve A^1 and prevents the escape of high-pressure water. When the propelling water passes out of the turbine of the train it still has a considerable velocity, which would take it out of the track if the momentum due to this velocity were not destroyed. This is done by means of a deadening apparatus, one being placed opposite to each injector. This is shown in Figs. 4 and 5, Fig. 4 being an elevation looking from the injector, and Fig. 5 a section. The framing is made of sheet iron, and the water from the injector, after passing the turbines, is received in the chambers shown and broken up. It is guided downwards, and its velocity is still further reduced by means of the chains suspended from the plates as shown. The water is finally collected in the trough between the rails and conducted to the reservoir to be used over again.

It remains to describe the apparatus for starting or stopping the train by opening or closing the injectors so as to start in one direction or the other. The cocks shown in Fig. 6 start the apparatus from the tender as desired by the driver or guard of the train. When the train stops on the track for any reason the injector which happens to be engaged with the turbine of the train is at an undetermined spot in relation to the length of the train, and the driver must be able to open or shut this injector quickly without leaving the tender, which is his post of control, or the train might be stopped suddenly by a signal leaving a jet from an injector still working. This the driver must be able at once to shut, and also to open when he wishes to start. The apparatus by which this is accomplished is shown in Fig. 10. A hollow rod B^1 is suspended under each vehicle, and runs along its whole length. It runs in bearings fixed under the cross-beams of the carriage, and is fixed in the vertical plane passing through the middle of the extreme positions C^1 C^2 of the arm or tappet which opens the injector. This rod B^1 carries by means of arms D^1 the rods E^1, which also run along the whole length of the carriage, and are so arranged as just to clear the tappets C^1 C^2 when in the middle position. A pinion F^1 is keyed on to B^1, and this works into a rack G^1, which prolonged passes through the cylinder H^1 and is attached to the piston. Two springs, one on each side of a collar on this piston rod, tend to keep it in its middle position, as also does the weight of the rods E^1 and the arms D^1. Two pipes J^1 K^1, which run the whole length of the train, can convey the liquid to either side of the piston, the pipe J^1 communicating by means of the pipe L^1, and the pipe K^1 by means of the pipe M^1. One end of each of the pipes J^1 K^1 is joined to a small receiver on the tender, and the whole, pipes, cylinder, and receivers, are filled with glycerine. The upper part of each receiver communicates with a small accumulator filled with compressed air. The various connections are governed at will by means of a pair of connected controlling cocks situated on the tender and shown in Fig. 6. Each of the two connected cocks can cause its corresponding pipe to communicate either with the accumulator on the tender, by the pipe N^1, Fig. 6, or with the free air reservoir by the two pipes O^1 O^2. The three pipes J^1 N^1 and O^1 and K^1 N^1 and O^1 open into the casings of the cocks by apertures which divide the circumference of the casings into three equal parts. The position of the pipes O^2 is given by the fact that they must be opposite to the openings of the plugs when they are in the "stop" position—*i.e.*, when the train is stopped they must be open to the free air. The plugs of the two cocks are connected by a pair of spur wheels of equal diameter in such a manner that when the handle R^1 of the one is turned the plug of the other is forced to turn to an equal extent in the opposite direction. Thus, when the handle is at "Forward" on the dial, the pressure liquid enters by the pipes N^1 and K^1 into the cylinder through the pipe M^1, and this drives the piston of the cylinder H^1 to the left, and thus raises the system B^1 D^1 E^1 into the position shown by the dotted lines opening the injector. During this forward motion of the piston the liquid contained in the other side of the piston escapes by the pipes L^1 and J^1, and through the cock by the aperture, and into free air. If the handle is moved through a third of a revolution the contrary movement takes place, and the injector is shut. Again, when the handle points to "Stop" on the dial, each of the two pipes J^1 and K^1 is placed in communication with the free air, and the piston is in the middle of its stroke. M. Barre states that this apparatus can be operated without effort, and that it acts with rapidity and smoothness. This railway possesses the most powerful possible brake, and the trains arrive and stop very quickly in all stations. In order to provide against any shock against the safety buffers in terminal stations, a ramp of wrought iron rises up from the track between the rails at a distance of some metres from the end. This ramp is intended to shut the feed cocks of the slides in case the driver shall from any reason omit to do so. No arrangements are shown for crossings or for junctions, and these will certainly present serious difficulties with this form of rail. From our description and remarks it will be seen that the system is likely to be little more than a mechanical curiosity—an ingenious one, it is true—yet nothing more, and its great expense alone will prevent its coming into general use, even if it were otherwise practicable.

THE FRICTION AND LUBRICATION OF CYLINDRICAL JOURNALS.

AT a meeting of the Manchester Association of Engineers, held on the 22nd ult., Mr. John Goodman, A.M.I.C.E., Professor of Civil and Mechanical Engineering, Yorkshire College, Leeds, read a paper on the above subject.

After stating the general laws of friction, the author proceeded to describe Thurston's, Towers', Stroudley's, and his own testing machines. He then summarised the conditions upon which the friction of lubricated surfaces are dependent, as follows:—(1) The intensity of pressure between the sliding surfaces; (2) the velocity of sliding; (3) the temperature of the journal; (4) the shape of the brasses and position of oil grooves; (5) the method of lubrication; (6) the materials of which the sliding surfaces are composed; (7) the time the load acts upon the bearing; (8) the physical properties of the lubricant.

A meagrely lubricated surface is in an intermedate condition between dry and wet, and the way in which the friction varies with the pressure entirely depends upon the efficiency of the lubrication. The relation between the frictional resistance and pressure with bath lubrication is shown by the formula $F = \frac{P + 10000}{K}$, where P = total pressure normal to the surface and K a constant determined by experiment in each case. In the case of pad lubrication the following formulæ are approximately correct:—First (saturated pad), $F = \frac{P + 500}{K}$; second (ordinary pad), $F = \frac{P + 50}{K}$.

Mr. Wellington, Professor Kimball, and others found that the friction of journals revolving at a very low speed is abnormally high and gradually decreases as the speed is raised to about 100ft. per minute. This is illustrated by a series of tables. Beyond the speed named Mr. Towers' experiments show that the friction varies approximately as the square root of the speed when the lubrication is good, the load in every case being over 400lb. per square inch. The author's experiments show that when the nominal load per square inch is below 60lb. the frictional resistance regularly decreases

Digitized by Google

with a reduction of speed, but when the intensity of the load is greater the frictional resistance falls below about 50ft. per minute. This appears to be accounted for by the fact that the greater load squeezes the lubricant out at low speeds. If the speed remains constant the load at which the change point occurs varies in an inverse ratio to the temperature, the lubricant when heated becoming more fluid and more easily squeezed out. This action is aided by any jar or vibration of the bearing. Generally speaking, the friction varies inversely as the temperature of the journal, so long as the temperature is not excessive. The varying viscosity of the oils used renders it impossible to formulate anything approaching a definite law.

As the result of over a thousand experiments made by the author in 1886, he found that the frictional resistance of a brass may be enormously reduced by cutting away the sides. For instance, if the width of the brass be made one-half the diameter of the journal, the friction will be less than one-half that of a semi-circular brass. The practice of railway engineers confirms this, as the width of the brasses is usually $\frac{5}{8}$ to $\frac{3}{4}$ the diameter of the journals. The author is of opinion that when a reduction is made the brasses should not be made less than $\frac{7}{10}$ of the diameter. In making a number of experiments with brasses which were bored on the crowns, the author found that the oil escaped through the hole so formed. He fitted the oil-hole with a screw-down valve, and found that when the valve was closed the friction was reduced 25 per cent., returning to the higher value when the valve was opened. From further experiments made the author demonstrated that the practice of putting oil holes or grooves along the resultant line of pressure is radically wrong and should be studiously avoided.

There are three methods of lubrication—bath or perfect, pad, and siphon lubrication. The advantages of bath lubrication were many, but it is sometimes urged that it cannot be carried out in practice. Pad lubrication is effected by a woollen or felt pad kept soaked with oil and lightly pressed against the journal, the necessary supply being obtained by lamp cotton communicating with a reservoir or by an ordinary siphon lubricator. This system is very economical, this being demonstrated by the following experiment:—A new pad weighing 14 drachms was supplied with 2¼oz. of rape oil and placed in contact with a 7in. journal, the total load on the brass being 4,984lb., or 237lb. per square inch. At the end of 319,660 revolutions, equivalent to 1,239 train miles, the pad was weighed, and found to be 2oz. 2drms., only 1oz. of oil having been used. The velocity was 166 revolutions per minute, the mean temperature of the journal was 130° Fahr., rising to 145° Fahr. at the end of the experiment; the mean coefficient of friction was 0·010, rising to 0·012. Siphon lubrication not only wastes oil, but very inefficiently reduces the friction. In some experiments made by the author to determine the rate of deterioration of oil, it was found that every time the oil was used in a siphon lubricator it lost about 5 per cent. of its lubricating property, the temperature and friction both being higher. The relative values of the three systems are shown in the following table, the friction produced being thus clearly shown:—

	Oil Bath.	Saturated Pad.	Ordinary Pad.	Siphon.
Towers.....	1·00	—	6·48	7·06
Goodman	1·00	1·32	2·21	4·20

With reference to the nature of the bearing surfaces the author's experiments show that there is little variation with different kinds of gun-metals, that white metal patches are distinctly an improvement, and that cast iron when well lubricated gives good results.

The effect of time upon lubrication was dwelt upon, and Professor Goodman said that, to avoid the squeezing out of the oil when a journal runs under a constant load, that load must be much smaller than if the load were only applied for a short space of time. For instance, the dead load on axles rarely exceeds 450lb. to 500lb. per square inch, while in connecting rods, where the load is applied for the fraction of a second, it often amounts to 2,000lb. per square inch on the big and 5,000lb. on the small end.

The function of a lubricant being to separate the metallic surfaces of a journal, the resistance to sliding becomes simply that of shearing this thin film of oil. By a special apparatus the author has succeeded in measuring this film, and finds it to be from ·0001 to ·0004 of an inch, which almost exactly agrees with Professor Reynolds' calculation. The shearing resistance of an oil is simply another term for its viscosity or "body." The greater the viscosity the greater the resistance to shearing, and the frictional resistance of a well-lubricated bearing depends upon the viscosity of the lubricant. It does not follow that an oil with a low viscosity should be chosen, as it squeezes out more readily. There is, further, the influence of temperature, which rapidly reduces the viscosity of an oil. For this reason solid lubricants are sometimes advantageously used, although the natural coefficient of friction and the temperature are much higher than is the case with oil. The natural coefficient and temperature are those to which a bearing attains when running with an ample supply of lubricant under a given load and speed. After standing, however, oil often gets squeezed out, and a good deal of frictional resistance and heating occurs which do not happen with solid lubricants. This is shown by the following table, the load being 58lb. per square inch: u = coefficient:—

Lubricant used.	Natural u	Temperature C.	u of rest after standing 16 hours.	Ratio of u of rest to natural u.	Ratio of Natural u.	Ratio of Rest u.
Bells' asbestos oil.....	·0084	34°	·192	22·9	1·0	2·1
Price's valve oil { B thick..	·0252	50°	·147	5·8	3·0	1·6
Price's valve oil { A viscous	·0329	37·5°	·1715	5·2	3·9	1·9
Bells' Asbestoline ..... } Hard solid grease ..... }	·0350	40°	·09	2·6	4·2	1·0

The author then proceeded to give the result of a number of experiments in which the chord of the brass was reduced. The arrangement must be such that the resultant line of pressures bisects the chord at right angles, in order that the wear may be symmetrical about that line. He contended that with a well-fitting semi-circular brass the wear takes place on the "off side" of the brass, and continues to do so until it subtends an angle of about 100°, when the wear becomes central. If the chord be still further reduced, the wear takes place on the "on side," as it does with a loosely fitting brass. The wear was greater on the off side, even with narrowed chords, when a groove and oil-hole was placed at the top of the brass. The author is of opinion that the film of oil carried round by the shaft exercises a wedging action, and forces the shaft over to the off side. If, therefore, the brass be reduced in width the area of the wedge would cover a greater proportional surface of the journal and make the wear more central. The presence of a groove and oil-hole at the top of the brass in the line of pressure was strongly condemned, as in every case experiment showed that it resulted in imperfect lubrication of one part of the bearing. It was recommended that the bearings should be made to subtend an angle of 90°, the wear being then nearly central.

Dealing with the general design of bearings, Mr. Goodman thought that, instead of taking the load per square inch as a basis of design, the number of thermal units a given area is capable of conducting away was better. The result of several thousand experiments showed that a gun-metal bearing working on a steel axle will keep cool when one square inch of surface is allowed for every thermal unit conducted away per minute. Let P = total pressure in pounds on the journal, w = the assumed coefficient of friction, s = the speed of journal surfaces in feet per minute, A = nominal area of brass in square inches, *i.e.*, length × width of chord, and r = revs. per minute, the values of u being given as follow:—

	Above 100ft. per Min.		Below 100ft. per Min.
Bath lubrication ...	·010	.....	$\frac{0{\cdot}12}{s}$
Pad do.	·012	.....	$\frac{0{\cdot}12}{s}$
Siphon	·015 to ·02	.....	$\frac{0{\cdot}15}{s}$ to $\frac{0{\cdot}2}{s}$

Then the frictional resistance = P u : foot lbs. of work done per minute = P u s : thermal units generated per minute = $\frac{Pus}{772}$: A = $\frac{Pus}{772}$. Wherever practicable, bearings should have about 1 per cent. of their length of end play. The brasses should never subtend more than an angle of 90°, the sides being cut away and pads inserted. An engine fitted with bearings of this type gave a mechanical efficiency of 90 per cent., and the report of its test stated that "the amount of lubricant used during the experiment was very small indeed." The right lubricant should be found by experiment, and once found should always be used.

The author then dealt with the question of ball bearings, and referred to certain experiments he had made with an ordinary "Rudge" bicycle bearing. The following laws appear to hold for the special bearing used:—(1) The coefficient of friction of ball bearings is constant for varying loads, hence the frictional resistance varies directly as the load; (2) the friction is unaffected by a change of temperature. The coefficient of friction with ball bearings is rather higher than that of plain bearings when bath lubrication is used, but it is lower than when they are lubricated by the ordinary methods.

The discussion on this paper was opened by Mr. Buckley, who said that, while he did not question the accuracy of the experiments made, he did not agree with some of the author's conclusions. He thought a bearing wore on the on side, for as a shaft was a roller the tendency was always to the front. If the side of the bearing was removed he contended the shaft would roll out, and for that reason the proposed construction of pedestal would be quite inapplicable to the case of a mill engine or shafts. The question of lubrication was a most important one, in view of the increase in the size of mills, and generally he questioned whether there was much improvement during the last thirty years. The application of a bearing determined its shape, and this was a cardinal feature. In one case of a bearing 10in. or 12in. diameter by 2ft. 6in. long, with a heavy weight upon the shaft, the difficulty of heating had been overcome by cutting in the journal three recesses or grooves, so that these became filled with oil, and thus fed the rest of the bearing.

Mr. Hans Renold gave some particulars of American bearings which he had running, and said this question appeared to be more closely studied in America than in England.

Mr. John Taylor said the proposed bearing was very old. Continuous feed pedestals had been made by one firm in Manchester for many years with great success. In many cases the brasses were made too thin, and bent up so as to clip the shaft, scraping off the lubricant and causing heating. The item of cost too often interfered with a good job, as manufacturers did not pay a price permitting of a perfect piece of work.

Mr. Nasmith said that it appeared to him the paper was of value as formulating a number of facts which were useful. It was hardly possible to put a 10in. or 12in. shaft into a testing machine, but the results obtained with smaller sizes gave an indication of the behaviour of all shafts. He thought the plan named by Mr. Buckley was practically bath lubrication, and saw no reason why the construction advocated by Professor Goodman should not be successful. The Mohler pedestal and the American type of universal bearings were successful instances of continuous lubrication, but the most striking instance of the continued use of oil was probably found in the quick running spindles in ring frames. These revolved 9,000 times a minute and ran for six to nine months with one small charge of oil, the abrasion being very slight in that period. In the care of shafting within a mill or workshop there was a good deal of room for improvement, as it was certain that an enormous loss of power arose from the imperfections of the bearings of line shafts.

Mr. Daniels said that his experience showed the accuracy of the author's conclusions with regard to railway practice. It was found that if too large a brass was used it was not long before a knock of the journal developed.

Mr. Buckley explained that he did not advocate a tight-fitting bearing, and it was a common practice to counterbore steps, side bearing being an evil, except in cases of side pressure. He knew of a pair of necks, 14in. in diameter by 2ft. 3in. long, on a shaft making 54 revolutions and developing 1,100 h.p., the oil consumption of which was one pint each per week.

Mr. Constantine said his experience with marine engines bore out Mr. Goodman's remarks. He had known cases in which brasses were grooved at the bottom, without being bored, with good results. When he was engineer of a large Atlantic liner, at that time the largest afloat, in one of the trips westward heating of one of the journals was incessant. On examining the journal in New York flaws were found, and grooves were cut in with round-nosed chisels to find their extent. The result was that on the return trip the journal worked satisfactorily without heating.

Mr. Rea said the importance of the subject was very great. He had known cases where, out of total power of 1,000 or 1,200 h.p., the friction diagram represented 170 to 200 h.p. He thought it would pay millowners to employ engineers to periodically test bearings. He objected to the pad, because he thought it got dirty and gritty. In dealing with the bearings of large shafts, he made the brasses square on the outside and cut out grooves in the corners, thus providing oil storage. The weight on the journal should be reduced to its lowest point. He had under his charge an engine, which had been running continuously every week from Monday morning to Saturday evening since 1884, the slide block of which had never touched the slide bar during the whole of that time. It was therefore possible to perfectly lubricate sliding surfaces.

Mr. Marshall said his experience showed him that to cut away the brasses as suggested was quite feasible and tended to preserve the shaft. He had an upright shaft working, the footstep of which had not seen the light of day since 1867, and had not in that time worn down ⅛in.

Mr. Goodman, in reply, said that locomotive bearings always wear forward. Pads may be old, but the question was, how many are used? He had cured a number of chronic hot bearings by the adoption of bearings on the principle he had indicated. The brasses must, of

Digitized by Google

course, be arranged to suit the resultant lines of pressure. If asbestos pads were used no danger of firing occurred, nor did pads clog if mineral oils were used. If the sides of the brasses were cut away they could not pinch in. End play in shafts was important, and the cutting of spiral grooves was also beneficial. Grooves without oil holes were valuable, but were worse than useless if oil holes were provided. He was engaged in the construction of a testing machine by which loads up to 20 tons could be applied, and he hoped to get a number of valuable results from it. He entirely disagreed with Mr. Buckley's contention as to the rolling action of a shaft, and maintained that in a well-fitting bearing the off side would always be worn.

THE CENTRAL ELECTRIC SUPPLY STATIONS OF PARIS.

Central station lighting has developed very rapidly in Paris since last year; an account of some of the most important may, therefore, be of interest to English readers. We will discuss the following central stations in turn:—

1. Cie. Française, on the compressed air system.
2. The Cie. Française, on the rarefied air system.
3. Cie. Edison.
4. Société anonyme pour la transmission de force motrice.
5. Société anonyme du Secteur de Clichy.
6. Municipale.
7. Various.

The Central Station of the Compagnie Francaise pour l'Air Comprimé.—In 1883 M. Popp installed a system of distribution of power by means of compressed air. The works are situated at the Lac St. Farjeau. This mode of distributing power has already been described in this journal, so a further explanation is unnecessary. The reader may be reminded, however, that on the 1st July, 1889, the power of the works of St. Farjeau was 3,000 h.p., and the length of the main arteries of distribution of compressed air was 55 kilometres. Since that time M. Popp has utilised compressed air in setting up a large number of small electric light installations, the dynamos being driven by compressed air motors. Among the most important installations are those of the Rue de Bondy, of 50 h.p.; the Passage des Panorames, 100 h.p.; la Rue Caumartin, le Boulevard des Capucins, 50 h.p.; la Rue Ste. Anne, 20 h.p.; la Rue de la Franche Comté, 20 h.p.; and the Théâtre des Variétés, 50 h.p. This system of distribution of power by compressed air permitted a great extension of house-lighting at a time when large electric light stations did not exist, and the installations in private houses have been very numerous.

In 1888 the Conseil Municipal de Paris went into the question of granting concessions for electric lighting to several companies. M. Popp applied for a concession for one section of Paris, and it was granted to him. He was thus obliged to change his mode of distribution. He devoted himself to the development of three sub-stations which could distribute electrical power direct to private houses. These stations are as follow:—

1. L'Eden Théâtre.
2. Buen-Retiro.
3. La Bourse de Commerce.

The first two have been completed, and are in actual use; the third station is still in the hands of the contractors. Before the company reduced its system down to three stations it had several small installations, which have since disappeared, but which are well worthy of description. In Rue Meyerbeer there was a sub-station with accumulators charged from the Eden Theatre station, but it has since been shut down. During the Exhibition there was also a station on the Boulevard des Capucins driven by compressed air motors, and it supplied 40 Thomson-Houston arc lamps installed on the boulevards by the Popp Co. These lamps are now supplied from the station of the Buen-Retiro or from the Eden Theatre.

The three main stations may now be described.

The Eden Theatre Station.—This station is established in the basement of the theatre. It consists of two compressed air engines of 50 h.p. each, by Messrs. Davey, Paxman, & Co. A six-horse vertical engine works an Anthonay ventilator. Each of the air motors drives an inverted Gramme machine giving 500 volts and 70 amperes. These machines charge accumulators fixed in different places. Special batteries of accumulators are devoted to the supply of the Eden Theatre. Three batteries supply a neighbouring café, and three others Les Montagnes Russes, an establishment close to the station. At first, Les Montagnes Russes had a compressed air motor of their own, which is now replaced by this battery. The station also has a Thomson-Houston dynamo, giving 2,000 volts and 6·4 amperes, feeding 48 Thomson-Houston arc lamps. The Eden Theatre station is connected with that of the Buen-Retiro, so that in case of accident to either the other can supply power for both.

The Buen-Retiro Station.—This station is not supplied with power by compressed air, but has its own steam engines. The generating plant consists of six locomotive boilers of 50 h.p. each by Messrs. Davey, Paxman, and Co., and six double-cylinder 50 h.p. horizontal engines by the same makers. There are four 2,400 volt Thomson-Houston arc lighters, and two inverted Gramme dynamos giving 250 amperes and 110 volts. These last charge eleven batteries of 50 Philippart cells each.

Bourse de Commerce.—As will be explained immediately, this station should be a very important station in the near future. As it was very requisite to distribute electric power in this district, a provisional service has been established. This consists of two 50 h.p. tubular locomotive boilers by Messrs. Ransomes, Sims, & Jefferies. They drive two inverted Gramme machines, giving 110 volts and 250 amperes each, and these charge two batteries of fifty Gadot accumulators, having a mean capacity of 300 ampere hours. These accumulators in their turn, charge others at distant points of supply. There are installations run in this way at the Bazar de l'Hôtel-de-Ville, and at a furrier's (MM. Révillon). In the latter there are five batteries of 39 Philippart accumulators each. There are 1,300 or 1,400 16-candle lamps running at 10 volts.

There are already two compressed air Davey Paxman motors of 50 h.p. each, and there will be eight or ten. Each of these motors works a high-pressure continuous current, and in each circuit an apparatus invented by M. Solignac will be placed. This apparatus consists essentially of a rotating drum which introduces variable resistances. This causes the main current to vary, and the variable current so produced is to be used to work transformers.

The reader will see from this account that the installations of M. Popp can hardly be taken seriously. Distribution of power by compressed air can never be economical, as an elementary knowledge of thermodynamics would seem to show. Moreover, the distribution of power by means of artificially varied direct currents and transformers will not strike electrical engineers as very promising.

(To be continued.)

NOTES ON ALLOYS.

III.

Mr. James Riley has recently given the public his views and experience on the new steel alloys. He stated in his lecture to the Greenock Philosophical Society that the use of aluminium in the manufacture of steel is not so advantageous as is usually maintained. Although when added to molten steel it greatly increases the fluidity of the mass and lowers the melting point, and thus enables sound castings to be made, equally good results can be obtained without its use. The strength and ductility of the steel is also not improved by additions of aluminium. In speaking of the chromium steels, which are being used for protective plates, he pointed out that the expense of this metal was a considerable drawback to its general use, not only on account of its original cost, but owing to the great loss incurred by oxidation of the metal in the manufacture of the alloy. Considerable care and skill are required in the production of chrome steel to get the necessary amount of chromium alloyed to the steel in presence of the requisite quantity of carbon. As a general result of adding chromium to steel, he points out that increased hardness and strength is accompanied by a slight loss of ductility and greater difficulties in machining. It can be very readily hardened and tempered in water or oil, but in working at the hammer or rolls care must be taken that the masses of steel are heated very gradually and not to a high temperature. He praises in very warm terms nickel steel, and believes it to be "the most important of the alloys, and the one which is likely to prove of greatest interest, because of its great utility." With the addition of 7 per cent. of nickel to the steel, the hardness and tensile strength are considerably augmented, and at the same time the elastic limit is raised, and the finished product is far more durable and less liable to corrosion than the best unalloyed steel. With a larger percentage (from 7 to 20) the alloy becomes brittle and practically valueless for machining, but with a still greater proportion of nickel the alloy again possesses great ductility, high tensile strength, and non-corroding properties. Nickel steel, if used for boilers, can be safely employed for nearly double the ordinary pressure without increasing the weight or dimensions. We have already alluded to the recent discoveries of large quantities of nickel ores both in America and Europe, so that there seems no reason for doubting that nickel steel can be manufactured at prices which will not be considered at all unreasonable.

Some of these new steels have recently been examined by Herr A. Ziegler with a view to ascertaining the most convenient and ready method for estimating the percentage composition of the alloy. As these alloys are introduced into the manufacturing world, it will be very necessary that their chemical composition be checked, as slight variations in the amounts of the added metals give very marked changes in the physical properties of the alloys.

Herr Ziegler at present has only worked out processes for the tungsten and chromium alloys, of which the following is a short abstract. Those of our readers who may desire further details of these processes may refer to the original paper in *Dingler's Polytechnic Journal*, 274, 513–528. Ferro-tungsten is best analysed by warming a known weight of the finely powdered alloy for some time with dilute aqua regia, and finally evaporating the solution with excess of strong nitric acid to as near dryness as possible. The residue is then treated with ammonium nitrate and nitric acid, and filtered. The insoluble portion consists of tungstic acid, silica, and any unattacked alloy, while the filtrate contains iron and manganese and traces of silica and tungstic acid. The tungstic acid and silica in the residue can be dissolved from the unaltered alloy by hot ammonia, filtered, evaporated, dried, ignited, and weighed. Mercurous nitrate can be used to precipitate the traces of tungstic and silicic acids in one portion of the solution, while the iron and manganese is estimated in another. The silicon is best obtained by difference—that is, after having found the total weight of tungstic acid and silica, the mixture is heated with hydrofluoric acid and re-weighed, the loss being equal to the amount of silica present.

Tungsten steel is analysed by first warming it with 80cc. of nitric acid, sp.g. 1·2, and then adding 100cc. of sulphuric acid (1:3) and evaporating until acid fumes begin to be evolved. Water is then added, and the residue, consisting of tungstic acid and silica, is weighed, treated with hydrofluoric acid, and re-weighed as in the case of ferro-tungsten. The filtrate is used for estimating the iron and manganese, and carbon is determined by Eggertz's method.

Ferro-chromium is best obtained in solution by fusing it with sodium nitrate or a mixture of sodium carbonate and potassium nitrate. The melt is extracted with water, the solution containing the chromium, and the residue iron and manganese. This residue is then dissolved in hydrochloric acid, and any insoluble residue re-fused. The solutions are then mixed and acidified, evaporated to dryness, and the residue weighed as silica and confirmed by treatment with hydrofluoric acid. The solution containing iron, manganese, and chromium is then examined as follows:—

Sodium hypophosphite is added to the boiling solution until the colour is pure green and zinc oxide stirred in while still hot; the precipitate is quickly filtered, washed, re-dissolved, the reduction and precipitation repeated, the precipitate dissolved in hydrochloric acid, precipitated with ammonia in excess, dried, ignited, and weighed as chromium oxide. Chromium steel is soluble in hydrochloric acid, and is examined in a similar way to the ferro-chrome. The author does not advocate the use of copper ammonium chloride. Carbon is best estimated by burning the finely divided alloy in oxygen, as Eggertz's method cannot be relied on unless chromium steel be taken as a standard.

THE SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

At the annual meeting, held on the 1st inst., Dr. Bailey gave an outline of a paper which he hoped to give in detail at a future meeting. The subject was a novel one, being a ready method of analysis by finding the specific gravity of a compound without weighing it.

Mr. Grimshaw then communicated two laboratory notes. The first referred to some experiments he had been making to determine the dissociation point of some of the metallic chlorides. The method of experiment employed was to titrate a known weight of the solution of the chloride with decinormal silver solution, expose the same weight of the solution to various temperatures, and titrate again. An indication was thus obtained of the loss of chlorine. Mr. Grimshaw stated that the dissociation of chlorides was an important point in the textile industries, especially where the goods had to be heated.

The second note was on an improved form of air-bath. There is a double casing, and there are arrangements for a constant temperature being obtained. The apparatus is made of sheet iron and brass instead of copper.

Digitized by Google

GLASGOW AND SCOTTISH SECTION.

At a meeting, held on the 1st inst., Mr. R. R. Tatlock, Glasgow, contributed a short paper on "The Fatty Acids of Olive and Other Oils." He said that in estimating the fatty acids in olive oil soap he had noticed that after the acids were completely dried they continued to lose weight by exposure to the heat of the water oven, which was usually at a temperature of 190° Fahr. That this loss resulted from the volatilisation of some acid body which had been in combination with soda there could be little doubt, and subsequent experiments confirmed that view. He was of opinion that this volatile substance was in reality a portion of the true fatty acid.

A paper on "The Estimation of Cobalt and Nickel" was then read by Mr. James Hope. He said that the separation of cobalt from nickel had always been a matter of difficulty to the chemist, and he thought he was justified in putting on record a complete process which, although not quite new, was not generally known. That process consisted of two operations—separation and determination of the cobalt by the "phosphate method," and the determination of the nickel by electrolysis.

LIVERPOOL SECTION.

At the annual general meeting, held on the 2nd inst., a paper was read by Mr. E. J. Ballard on a new method of using luminous calcium sulphide (Balmain's luminous paint) for actinometrical purposes, with description of a new actinometer for photographic purposes. The author described a new actinometer he had constructed, in which advantage is taken of the rate of fading of calcium sulphide illuminated to its maximum intensity by a preliminary exposure to daylight. The law regulating this rate of fading had been worked out, and a table constructed from the curve obtained.

Mr. A. F. Fryer communicated a note on a beautifully crystalline boiler deposit, taken from the boiler of a steam tug. It consisted essentially of anhydrous calcium sulphate, together with a little meno-hydrated magnesium sulphate (kieserite) and alumina. In appearance it resembled satin-spar, and was crystalline throughout almost the whole of its mass.

Dr. F. Hurter described a most ingenious instrument he had contrived for the measurement of the intensity of diffused daylight, and also exhibited the "Actinograph."

Notes.

A NEW STEEL WORKS IN WEST CUMBERLAND.

THE new steel works, erected by the Hampton and Facer "Special" Steel Ingot Company, at Maryport, Cumberland, were started on Thursday in last week, in the presence of a large number of gentlemen interested in the iron and steel trades. When completed the works will include rolling mills and a foundry, and will give employment to about 400 hands. The company was formed for the purpose of working out a new system of ingot casting devised by Messrs. Hampton and Facer. The advantages claimed for the new system are numerous, and include greater soundness and homogeneity, the absence of the expense of "cogging down," the securing of good sound tops, and the regulation of the weight of each ingot. The Bessemer plant includes two 5-ton converters, two pig iron and two spiegel cupolas, four new hydraulic cranes, two centre-casting hydraulic cranes, and a pair of blowing engines. The blowing engines are by Messrs. Walker, Eaton, & Co., Sheffield, and will work up to a pressure of 25lb. per square inch. The output of the works will be about 1,000 tons per week, the principal portion of which will be supplied to the Sheffield trade for the manufacture of cutlery, springs, chisels, &c.

ARDROSSAN HARBOUR WORKS.

LAST week a special train was run from Glasgow to Ardrossan, with the board of directors of the Caledonian Company, in order that they might make an inspection of the new harbour works which have been under construction for some years past. When completed, which will be early next year, the harbour will be in every way suited for the carrying on of a large trade, which it is expected to develop, as it is in direct connection with the Lanarkshire and Ayrshire Railway, and thus offers a convenient point for both exporting and importing raw materials and manufactured goods. The present harbour resources include a wet dock of considerable size, and tidal quays, where cargo boats which do not go into the dock can be accommodated; while in connection with it there is a shipbuilding yard, with an excellent graving dock and slip, where shipbuilding and repairing may be carried on. The new works add a wet dock capable of taking in steamers of the largest dimensions, and a new tidal basin and piers which will give accommodation for a greatly increased traffic. The whole of the works are to be protected by a substantial breakwater, which will shelter the harbour from the force of the north-west storms. The area of the new dock will be nearly ten acres, and that of the new outer basin about seven acres, and they will have a depth of 18ft. and 27ft. at low and high water respectively. A contract has been made with the Hydraulic Engineering Company, of Chester, for a supply of all the most recent hydraulic appliances and for the machinery for working the dock gates. Station accommodation will be provided at the terminus of the Lanarkshire and Ayrshire Railway at the new pier, and the contracts for a large station shed have been given to Messrs. J. & G. Findlay, Glasgow. The firm at present carrying on the principal parts of the dock and harbour works is that of Messrs. Lucas & Aird, contractors, London, and the engineers are Messrs. Strain & Robertson, Glasgow. The cost of the whole works, when completed, is expected to be close upon £200,000.

STATE OF JOHANNESBURG.

THE present state of the town and district of Johannesburg is another example of the dangers arising from over-speculation, and too great a rush to any particular spot. Fortunes were being made—at least, on paper—so rapidly, that people of all kinds went to the district in crowds. Now, however, the reaction has come, and hundreds are leaving for Cape Colony, when they have the means to take them there. Those who have not the means have been reduced to dreadful straits. The cause of the depression is the state of the share market. Gambling in stocks became the chief occupation, and the people seemed to be governed by nothing else, and never thought of developing the mines and keeping up the return of gold to the anticipated yield; the town, in short, became a speculating and not a mining centre, and now when the banks, to secure themselves against loss, have called on all those who have overdrawn, the result has been the forced sale of property at ruinous prices. Still, however, building is going on, and the town is being very much improved, but drainage is bad, and fever is reported to be raging. Altogether it does not seem to be a very desirable place of residence.

REPORTED NEW LINES OF ATLANTIC STEAMERS.

IT is stated that the charter constituting a company for a fast line of steamers between Canada and Milford Haven has passed the Dominion Parliament, and is now before the Senate. The object of the company is to reduce the Atlantic voyage to something like 1,700 miles, as against 3,052 miles between New York and Liverpool. It is proposed to construct a railway along the north shore of the River and Gulf of St. Lawrence, from Quebec to St. Charles Bay, on the Labrador coast, a distance of 844 miles, and with steamers making 20 knots an hour it is expected that the voyage between St. Charles Bay and Milford Haven will be made in 3 days 13 hours. It is expected that this route will take the bulk of the Western passenger business, and of the shipment of perishable freight, as the distance from Chicago to London will be covered in six days. The names of those who are promoting the scheme seem to show that it is a genuine commercial undertaking, and that it will be prosecuted with energy. It is further reported that a syndicate has been formed for providing a fast line of steamers to be run between New York and Milford Haven, at a minimum speed of 20 knots an hour. The members of the syndicate are mostly Americans, and consist, among others, of the presidents of the three leading United States railways, and they intend to have all the ships built in the United States.

SUBSIDIES FOR AMERICAN SHIPPING.

TO carry out the idea of binding the various countries of North and South America into one large self-contained community, the Pan-American Conference has recommended that one or more lines of steam navigation should be subsidised between the ports of the United States and certain important South American ports. It is proposed that the countries receiving Government aid will establish a fast bi-monthly service between the ports of the United States and Rio Janeiro, Monte Video, and Buenos Ayres, and that the vessels shall have the accommodation and capacity necessary for the transportation of freight and passengers and shall carry the mails. The speed of the fast steamships is to be at least 16 knots an hour. In addition, an auxiliary line of freight steamships, to sail twice a month, making not less than 12 knots an hour, is recommended. The contracting States are to have the right to impose their flags and register on the vessels to a number proportionate to the percentage of the aid they pay. Only vessels constructed in the United States are to be accepted, in consideration of a higher percentage of aid paid by them. This last provision we consider a very acute one in the interests of the ironmasters and shipbuilders of the United States, for it not only secures to them a monopoly for their own country, but also for all the countries which agree to the terms proposed by the Conference. A very strong feeling is, however, being developed against measures of this kind in the United States, and possibly the proposals we have mentioned may not be ratified.

ARGENTINE SECURITIES.

FOR some years past the Argentine Republic, both as a Government, and by local loans of various kinds, has been one of the heaviest borrowers on the European money market, and, although the great resources of the country have been fully recognised, still it has been felt by those who took a statesmanlike view of the matter that too much was being attempted at one time. The too great hurry in every department has led to a financial crisis, and gold has in consequence gone up to a very high premium, and all Argentine securities have fallen very much in value. We think that the country has a great future before it, if it only be governed wisely, and we are pleased to know that the Government has resolved to meet the economic crisis by immediately adopting energetic measures. Considerable reductions have been made in the Budget expenditure for the present year, and next year's Budget will also show a great reduction in expenditure. The Government has ordered the suspension of all concessions with Government guarantees to new railroad companies and other undertakings creating fresh obligations. The Provincial Government is going to be ordered to suspend the issue of Mortgage Cedulas, and all the provinces will also be ordered to make no further issues of credit paper, and to abstain from working any exterior loans. The Government has resolved that all guarantees given to railway lines be paid on the 1st of January and 1st of July of each year, even if the accounts have not been examined and approved. The issue banks will not be allowed to increase their note circulation, and the Government proposes to diminish the issues made.

EXPLOSION AT THE BELL ROCK.

ON Saturday evening an explosion occurred at the Bell Rock, which had the effect of placing the lighthouse in darkness. About the middle of last month there was fitted up at the lighthouse a cotton powder explosive signal, which during thick weather or snow showers was fired once in ten minutes. The charges of cotton powder are connected by the wires of an electric fuse and detonator to a cable, attached to a lever or jib fitted to the roof of the lighthouse, and the electricity is supplied by a small magneto-electric machine placed inside the light room. The charges for producing the explosion consist of small cylindrical discs of dry cotton powder coated with paraffin, and having a small hole up the centre to receive the detonator, which is a copper tube containing a fulminating composition. Since the apparatus was erected the signals have been used during foggy weather, and the report is so loud that it is distinctly heard in Arbroath, at a distance of twelve miles. On Saturday night, when the weather was thick, and arrangements were made for the signals being fired, about ten o'clock one of them exploded prematurely, or, at all events, the explosion had the effect of injuring the dome of the lighthouse, which is also the light room. The windows were blown out, all the internal fittings smashed, and the framework of the room damaged. It is not yet reported how much damage is done to the machinery, but it is supposed that it is not very great. As, however, it is paraffin oil which is used for the light, it was impossible to light the lamps on account of the glass in the windows being smashed, and fog signals were fired every ten minutes as a warning to vessels. Workmen have gone from Edinburgh to repair the damage, and it is expected that the lighthouse will soon be in its normal condition. The man who was in charge at the time of the explosion was knocked down and rendered insensible, although he does not seem to have been injured otherwise than by the nervous shock.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents).")

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

24th March, 1890.

4556. Rainforth, Sen., Rainforth, Jun., & Rainforth ..... Screens for dressing corn.
4563. Hart, W. F..... Sole edge burnishing machines (*Gordon & Lewis*).
4564. Thomson, J..... Calico printing machines.
4565. Mud & Powers ..... Metallic tubes and cylinders.
4567. Cooper, W. ..... Loose pulleys.
4570. Leng & Leng ..... Bottle finishing machines.
4573. Shepherd & Midgley ... Grinding flats.
4574. Kasblowsky, E..... Gas motors.
4575-6. Tangyes, Ld., Floyd, & Morton ..... Steam pumps.
4578. Imray, O..... Sewing machine (*Welch*).
4587. Mariotte, A. ..... Grinding grain.
4589. Hornsby & Edwards ... Steam boiler.
4592. Parfitt, H. T. ..... Kilns for firing glass, &c.
4594. Jones, E. ..... Apparatus for separating liquids or solids from vapours or gases.
4597. Horne & Whinfield ... Turret guns.

25th March, 1890.

4611. Ainsworth, J. T. ..... Mules.
4613. Dean & Powell..... Consumption of smoke in furnaces.
4614. Guthrie, M..... Drying apparatus.
4617. Sturgeon, T. ..... Engineering constructions.
4618. Armstrong, R. ..... Hydraulic transmission.
4621. Gatling, R. J..... Torpedo boats.
4623. Wahlin, Lundstrom, & Collins ..... Separators.
4624. Hudson, H. ..... Boats, railway carriages, &c.
4630. Rickards, J. E ..... Machines for rolling cigars.
4631. Radford, R. H. ..... Casting composite ingots.
4632. Busby, A. E. ..... Splayed cotter machinery.
4638. George, O. ..... Printing machines.
4639-40. Fox, S. ..... Boiler flues, &c.
4642. Robinson, E. ..... Circular knitting machines.
4643. Masterman, C. E..... Condensers.
4648. Degn, P. F..... Dynamo-electric machines.
4653. Davies, E. ..... Hydraulic motors.
4654. Justice, P. M..... Machines for making springs (*Swift & Davenport*).
4655. Meydenbauer, A. ..... Gas engines.
4656. Lake, H. H..... Screw propellers (*Gibert*).
4671. Boult, A. J..... Steam engines (*Stanwood*).
4672. Baer, A. ..... Check valves for hydraulic apparatus.
4674. Thompson, W. P. ..... Heading bolts, rivets, &c. (*Seaton & Seaton*).
4675. Tiefford, R. J..... Welding of metals.
4676. Weston, P. ..... Anchors.
4677. Boult, A. J. ..... Propelling rotative tools (*Veds*).
4680. Gooding & Ladd ..... Mechanism for lasting boots.
4682. Longmore & Watson ... Combing machines.
4684. Foord, W. S. ..... Printing machines.
4686. Schneider, H..... Minimising recoil in ordnance.
4688-9. Potts, I. B. ..... Pipe couplings.
4691. Haddan, H. J..... Bolting reels (*Dobson*).
4693. Fox, S. ..... Metallic articles of box-like form.
4698. Mayhew, C. J. ..... Fluid motor.

26th March, 1890.

4702. Mayoh, J. ..... Joist for floors.
4706. Wear, S. ..... Sieving apparatus.
4707. White, J. W. ..... Measuring apparatus for liquids.
4708. Whitaker, R. M. ..... Boiler furnaces.
4709. Hart, G. W. ..... Steam generators.
4714. Wilde, O..... Steam engines.
4716. Punch, R..... Making rivets.
4717. Sauvée, A. ..... Gun mounting (*Canet*).
4719. Scott, L. A..... Oil-tight and water-tight joints.
4721. Watson, H..... Malt-drying kilns.
4722. Edwards, J. ..... Reversible rail, fish-plate, and chair.
4725. Gillespie, J., Jun. ..... Rolling mills.
4727. Fulton, R. J. ..... Rolling mills.
4731. O'Neill, S. ..... Machinery for making paper tubes.
4732. Birch, W. ..... Apparatus for filtering sewage.
4735. Averill, F. W. ..... Flush bolts.
4741. Gibbs, W. A. ..... Kilns for cement.
4742. Tangyes, Ld., Meacock, & Deakin ..... Hydraulic lifting jackets.
4750. Crossley, F. W. ..... Centrifugal governors.
4764. Gasteiger, J. ..... Boiler furnaces.
4768. Lundgren, F..... Machines for filling match boxes.
4769. Lake, H. H..... Machines for manufacture of cigars (*Wertheimer*).

27th March, 1890.

4772. Nield, W. ..... Spinning apparatus.
4774. Coutts, C. ..... Air and vacuum brakes.
4776. Donkin & Hargreaves Gas valves.
4778. Sykes, T..... "Fuel economisers."
4781. Schmitz, J. ..... Utilising waste gases from flues.
4784. Faulds & Hool ..... Lubricator.
4787. Thomis, Priestley, & Priestley ..... Jacquard machines.
4793. Moorhouse & Ogden ... Reeling machines.
4805. Duncombe, I. ..... Self-sustaining motive power.
4806. Barns, D..... Boiler flues.
4808. Haddan, H. J. ..... Vacuum drying apparatus (*Passburg*).
4810. Brunton & Brewster... Manufacture of projectiles.
4811. Davidson, J. A..... Lubricators.
4813. Jenner, T. ..... Weighing machines.
4817. Grafton, H. ..... Steam engines.
4819. Pryce, H. J. ..... Operating railway points.
4820. Judson, W. L..... Street railways.
4823. Otto, N. A. ..... Gas engines.
4825. English, T..... Transporting and working guns on railways.
4826. Lewes, V. B. ..... Preventing ignition of coal cargoes.
4828. Wright, R. ..... Cranes.
4829. Noble & Murray ..... Apparatus for working guns.
4832. Oakman, R. N., Jun..... Furnaces for melting metals.
4833. Wells, C..... Hot air motors.
4837. Templeton, E. A. S..... Machine for finishing pedestals.
4838. Templeton, E. A. S ..... Boring machine for pedestals.
4844. Wilson, J. H..... Textile machinery.

28th March, 1890.

4850. Collier & Binns ..... Heating metal plates.
4854. Heys, W. E..... Machines for dyeing (*Châtel*).
4856. Brooke, R. G..... Back pressure valves.
4858. Kapp, G. ..... Dynamo-electric machines.
4861. Marsden, H. M..... Manufacture of saws.
4866. Harbinger & Bell ..... Compound gland.
4867. Watts, J. W. ..... Knitting machines.
4868-9. Merryweather, J. C. Fire engines.
4870. Weir, J. ..... Looms.
4871. Watson, T. ..... Spinning flax.
4884. Maffuniades, A. J. ..... Paper cutting machines.
4886. Thompson, W. P. ..... Roller mills (*Willford*).
4887. Purves, D. ..... Fire bars.
4892. Allen, Wright, & Allen Steam engines.
4894. Van Ollefen, W. F. D. Lifting and lowering doors of bulkheads.
4895. Cucco, G. ..... Plate steam presses.
4896. English, T..... Mountings and carriages for disappearing guns.
4898. The Harrison Self-Tightening Steel Rail-Key Co., Ld., & John Harrison..... Securing nuts upon bolts.
4899. Tavernier & Casper ... Explosive engines.
4902. Mann, M. F. J. ..... Brakes.
4911. Topliss, J. R..... Machinery for distributing type.

29th March, 1890.

4912. Martin, R. ..... Engine governor.
4923. Dixon, W. E. ..... Mules.
4924. Dewrance & Wall ..... Water gauges.
4926. Mefford, D. M. ..... Projectiles.
4927. Siddall, C. ..... Signalling apparatus for railways.
4931. Cumming, W. B..... Controlling rudders.
4932. Bateman & Sellers..... Bench vices.
4937. Blachon & Mimard ..... Sporting guns.
4945. Mumford, C. E. ..... Grain elevators.
4947. Weiss, O. ..... Petroleum engines.
4961. Redfern, G. F. ..... Spinning machines (*Defraiteur & Maron*).
4963. Reixach & Bracewell... Pile fabric machinery.

31st March, 1890.

4964. Pope & Pope ..... Apparatus for separating ground substances.
4966. Wilson & Wilson..... Boats for life saving purposes.
4967. Claringburn, J. A. ..... Knitting machines.
4968. Radcliffe, J. H. ..... Oil vessels.
4969. Scotson, W..... Regenerative furnaces.
4980. Piatkowski & Came..... Transmission of power.
4990. Booth, A. T. ..... Sawing machines.
5001. Lake, H. H..... Puddling furnaces (*York*).
5002. Lake, H. H..... Machines for sharpening knives (*Peer & Ely*).
5005. Baxter, S. ..... Gas engines (*Holst*).
5007. Nunan, E. ..... Pipe coupling.
5009. Unger, R. ..... Machine for winding yarn.
5010. Hartmann & Thomson... Leather paring machines.
5012. Tinline, Jun., & Holt... Machines for planing wood.
5013. Foley, J. S..... Locking nuts.
5017. Kirchhoff, O. ..... Collapsible boats.
5019. Richardson & Dimant... Coupling railway carriages.
5021. Rittenhouse & Dresher Punching and shearing curved plates.
5022. Deans & Foster ..... Apparatus for twisting strands.

ELECTRICITY.

24th March, 1890.

4547. Wilkinson, J. ..... Electric wires.
4557. Andersen & Girdlestone Dynamo-electric machines.

25th March, 1890.

4605. Swinton, A. A. C..... Electric switches.
4650. Palmer, H. B..... Producing intermittent motion by electricity.
4657. Lake, H. H..... Soldering metals by electricity (*Thomson*).
4670. Imray, O..... Electrical heating devices for forging machines (*Gilbert*).
4699. Kellogg, M. G. ..... Telephony.
4700. Isenthal, A. W..... Arc lamps.

26th March, 1890.

4745. Essinger & Crampton... Dynamo machines.
4761. Mensing, L. C. H. ..... Producing force by explosions of water electrically.
4767. Sherrin, J. V. ..... Electromotors.

27th March, 1890.

4791. Douglas, W. H. ..... Measuring electrical currents.
4815. Smith & Heath ..... Ships' compasses.
4821. Obach, E. F. A. ..... Insulated electric conductors.
4824. Nebel, J. ..... Dynamo electric machines.

28th March, 1890.

4846. Andrews, W. ..... Electric lights.

29th March, 1890.

4921. Perry, J. ..... Galvanometers.
4943. Balch & Bromhead ..... Batteries.
4949. Weigert, L. ..... Galvanic batteries.
4952. Contarini, A. N. ..... Electric arc lamps.

31st March, 1890.

4972. Kennedy, R. ..... Arc lamps.
4973. Kennedy, R. ..... Dynamo-electric machinery.
4974. Kennedy, R. ..... Electric meters.
4984. Robinson, J. ..... Electric telegraph.
4991. Gay & Hammond ..... Electric arc lamps.
4992. Gay & Hammond ..... Electric recording apparatus.
4993. Gay & Hammond ..... Electric heating apparatus.
4994. Sinnock, W. ..... Obtaining currents of electricity.
4998. Nichols, H. G. ..... Electric lamps.
5008. Furtado, E. F. ..... Electro telephonic apparatus.
5016. Bary, C. P. ..... Alternating electric currents.
5023. Redfern, G. F. ..... Electricity meters (*Ferges*).

CHEMISTRY.

24th March, 1890.

4560. Teague, T. ..... Refining raw tin.
4577. Imray, O..... Colouring matters (*Farbwerke vormals Meister, Lucius & Brüning*).
4588. Precht, H. ..... Carbonate of magnesium.
4596. Pitt, S..... Sulphonated thiouines (*Cassella & Co.*).
4598. Gray, W. ..... Manufacture of gas.

25th March, 1890.

4690. Haddan, H. J..... Concentrating magnetic iron ore (*Conkling*).
4694. Lawrence, E. G. ..... Salts from brine (*Pick*).
4695. Lawrance, E. G. ..... Drying salt (*Pick*).

26th March, 1890.

4751. Cowper, E. A..... Producing fine salt from brine.
4752. Cameron, D. ..... Extracting silver (*Pearce*).
4759. Precht, H. ..... Hydrate of magnesia.

27th March, 1890.

4780. Thwaite, B. H. ... . Dechlorination of salt.
4798. Burghardt, C. A..... Nitrate of ammonium.
4809. Johnson, J. Y. ..... Soap (*Duclos*).
4836. Price, J. ..... Treatment of sewage.

28th March, 1890.

4904. Pitt, S..... Dyestuffs (*Cassella & Co.*).

29th March, 1890.

4930. Hay, Alexander, & Bentz ..... Indigo.
4946. Imray, O..... Ethylether of cinnamic acid (*Farbwerke vormals Meister, Lucius & Brüning*).
4950. Ellis, A. W. ..... Distillation of ammoniacal liquors.
4959. Kellner, C. ..... Sulphide cellulose.
4960. Kellner, C. ..... Purifying paper pulp.

31st March, 1890.

5003. Eaton & Vanderbilt ... Chromium.

MISCELLANEOUS.

24th March, 1890.

4542. Fawcett & Swallow ... Block fuel.
4545. Campbell & Cameron ... Fire hose couplings.
4546. Blake, J. W. ..... Ship's lamp.
4586. Macaulay, H..... Range finding instrument.

25th March, 1890.

4607. Crane, W. E. ..... Filtering oil.
4608. Longley, C. J. ..... Wood block flooring.
4615. Bower, H. ..... Joining driving belts.
4652. Mewburn, J. C..... Purifying brine (*Peck*).
4664. Clark, A. M. ..... Flexible tube (*Almond & Fretigh*).
4669. Tyer, E. ..... Fog signalling.
4681. Thompson, W. P. ..... Graphophones (*White*).
4683. Boult, A. J. ..... Dyeing yarns (*Koblenzer & Koblenzer*).

26th March, 1890.

4739. Buckman, T. F. ..... Hose pipes.
4743. Raikem, E. ..... Fire alarm.
4760. Gray, A. ..... Signalling apparatus.

27th March, 1890.

4792. Rylands & Husselbee... Glass lined piping.
4803. Honeysett & Stanley... Slide rules.
4822. Dombrain, H. A. A..... Extracting fatty matters.

Digitized by Google

28th March, 1890.

4847. Heys, W. E..... Tubes for spinning machines (*Châtel*).
4858. Berry & Shuttleworth Loom shuttles.
4855. Heys, W. E..... Tubes for spinning machines (*Châtel*).
4865. Barraclough, A. ..... Fire extinguishing apparatus.
4903. Samuels, W. O. ..... Extinguishing fires.

29th March, 1890.

4936. Girling, S. ..... Incandescent gas lamps.

31st March, 1890.

4976. Hawksley, G. W..... Boiling esparto grass.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

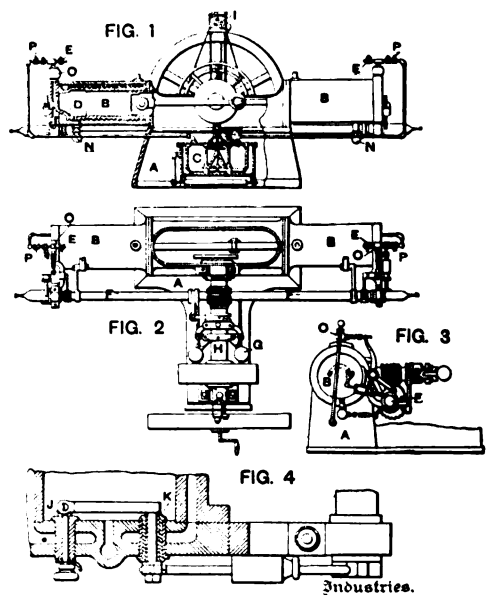
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Split Pulleys.—*W. Thomlinson-Walker, York.*—The invention consists of an improved jointing plate for connecting at the rim the halves of split pulleys. The rim is made of wrought iron, and to each half of the rim at its joints are riveted cast steel plates. These plates are made of such a shape, that when the two halves of the pulley are bolted together at the hub or boss, the plates dovetail into each other, thus taking up all the side strains at the rim joints. Through the dovetailed portions of the jointing plates a tapered hole is formed lengthwise with the rim. A tapered pin is driven into this hole and is screwed up tightly by a nut, thus closing the joint and at the same time causing the inner dovetailed part to expand and fit the outer dovetailed recess. Claims: (1) A joint in two halves, the boss or bearing of the one being split and the other being recessed, the said recess being slightly dovetailed; (2) the forcing into the dovetailed portion of the split half, and the opening of same by means of a tapered bolt or stud.—No. 9437. June 7th, 1889. 6*d*.



Carding Engines.—*J. Bullough, Accrington, Lancashire.*—By the use of this invention the distance of the flats from the cylinder may be accurately judged and greater accuracy obtained in grinding the flats and doffers and in adjusting them. The illustrations show parts of a carding engine with the improvements applied. At the top of the machine is a trough A with an open bottom. In

this trough, and protruding through the bottom, is a block of pipeclay B. The pipeclay is retained in the trough by suitable means, so that when the latter is raised and lowered by the handle C, pinion D, and rack E the bottom surface of the pipeclay will touch the ends of the wire or cards F as they pass to the cylinder G. If the wire upon the cards is in contact with the wire upon the cylinder the pipeclay will be removed, and will indicate the depth and extent of contact, so that the flats can be readily adjusted. In order to expedite the traverse of the flats during the time they are being tested, the pulleys and bands H I and J are employed in combination with worm K, shaft L, worm M, and wheel N to drive the carrying rolls O. When the grinding is effected through contact between wire of flats and cylinder, tendency to heat is prevented by the use of a flannel-covered roller. The roller is partially immersed in a trough of water and moistens the flats as they come into contact with it and cause it to revolve. Fig. 2 shows an alternative arrangement for colouring the wires of the cards by holding a block of chalk P upon the ordinary stripping brush Q. A spray of chalk dust is thus directed into the flats as they pass along. Claims: (1) The means herein fully described for ascertaining the space or distance between the wire of the flats and the wire of the cylinder; (2) the means and appliances herein set forth for effecting a nearer approach to accuracy in the grinding and in the adjustment of the flats to the cylinder; (3) the use and employment of colouring matter combined with appliances such as described for applying same to the wire of the flats for purpose of indicating degree of contact between wire of flats and wire on the cylinder; (4) the combination of appliances and flats whereby the traverse of the latter during its testing is expedited as described and illustrated.—No. 3236. February 23rd, 1889. 11*d*.

Steam Turbines.—*C. G. Patrik de Laval, Stockholm, Sweden.*—The invention relates to an improvement in turbines which are set in motion by means of a current of steam, the object being to increase by complete expansion the velocity of the steam current, thus producing relatively the largest quantity of *vis viva* of the steam. The steam supply way is constructed in such a manner that its cross sections are slowly increased in size as they near the turbine wheel, and that in the steam passage between these two sections a permanent current of steam is produced under isoëntropical expansion. Claim: In steam turbines the combination of the turbine wheel with a steam supply, the cross section of which increase regularly near to the turbine wheel and in the direction of the cam as and for the purpose specified.—No. 7143. April 29th, 1889. 6*d*.

Gas Engines.—*M. Rogers & J. A. Wharry, Terre Haute, Indiana, U.S.A.*—This a two-cylinder gas engine, whose connecting rod operates one crank pin, and whose controlling valves are operated by a single way shaft. The explosive mixture is preferably carburetted air, which is made in a carburetter attached to the engine. The ignition of the explosive charge is effected by an electric spark. In the accompanying illustration, Fig. 1 is a side elevation of the engine, Fig. 2 a plan, Fig 3 an end elevation, and Fig. 4 a section upon the end of a cylinder. The cylinders

B are water-jacketed, and their outer surface ribbed, so as to more readily give up their heat to the water. In the base A of the engine is situated the carburetter C, which is in communication with the combustion chambers D of the cylinders by pipes and the valves P and O. Air is admitted to the combustion chambers by the valves E and O. The products of combustion of the gases are extracted from the cylinder by the valves N. All the valves are operated by cams fixed to the way shaft F, which is driven through gearing by the crank shaft H. By the motion of the shaft F to the right or to the left (due to the motion of the governor G), the quantity of explosive charge may be regulated or entirely cut off. A small dynamo I generates the electricity for producing the electric spark. The spark is made at the required instant by a cam upon the way shaft F disconnecting two electrodes J K (Fig. 4), situated in the combustion chambers. The current passes through these electrodes when they touch, but when they are disconnected a spark is formed. The operation of the engine is as follows: The engine being turned by hand on the outstroke of each piston in succession, a charge of carburetted air of regulated strength and temperature and a charge of atmospheric air are drawn by suction through valves P, E, and O into the cylinders; on the return stroke of each piston the charges are compressed into the combustion chambers, and then fired by the electric spark produced by the igniting apparatus. When one engine is drawing in its charge the other is compressing its charge, and then fires it whilst the first engine compresses. The second engine then exhausts whilst the first is making its power stroke, then to exhaust in its turn. The exhaust products serve to heat the carburetter before reaching the atmosphere. The regulation of the speed is effected by the governor—that is, each cam is moved to the left as the speed increases, and the inlet valve lever drops from one cam step to another, thus decreasing the lift of the inlet valve; or if only one cam surface is used instead of the steps the gas inlet valve will at once fail to open. The two cams occupy such a relative position with respect to the inlet valves that the right-hand engine drops off the cam sooner than the left-hand engine, thus throwing it idle when excessive speed takes place, and at a still higher speed both engines run idle. Nine claims are made.—No. 10286. June 24th, 1889. 8*d*.

Locomotives.—*J. F. A. Mallet, Paris.*—According to this invention the cylinders of compound locomotives are arranged tandem fashion along the longitudinal centre line of the engine, instead of being placed side by side. The piston rods of the cylinders are independent of each other, and drive two centrally cranked axles whose wheels are coupled together in the ordinary manner with their cranks at right angles to each other. Or one of the pistons may drive a central crank, and the

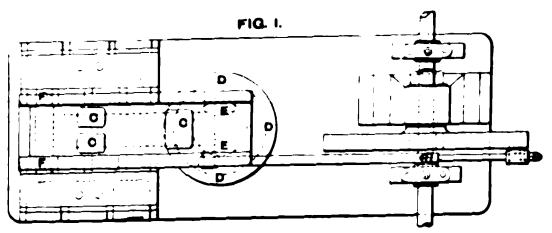
Digitized by Google

other piston may, by means of a cross-head and two outside connecting rods, drive outside cranks on the same axle but at right angles to the centre crank. By the above-described arrangements the inventor claims the two following advantages: (1) The efforts of the pistons are exerted only in the longitudinal axis of the engine, thus avoiding the oscillation due to the alternate action of the pistons situated at the opposite sides as in ordinary engines, and ensuring greater stability when running at high speeds; (2) by placing the low-pressure cylinder in the longitudinal axis of the engine the whole width between the side frame is available, and the cylinder can be 3ft. or more in diameter. Claim: A compound locomotive engine having the high and low pressure cylinders placed tandem-wise one in front of the other in the centre line of the engine, their pistons being coupled to cranks at 90° to each other by means such as described.—No. 8472. May 21st, 1889. 8d.

GAS ENGINES.—*H. Sumner, Kilmarnock.*—The novelty claimed by the inventor is the use and application of a travelling incandescent coiled or porous piece of platinum or other metal for the purpose of igniting the charge of gas engines, &c. The platinum is arranged and secured in a hollow cylindrical rod or tube, which is provided with holes at the point where the platinum is situated to expose it to the heat of the flame of a Bunsen burner. The tube is given a reciprocal sliding motion in the direction of its axis by means of a cam, eccentric, or other suitable device worked by the motor. The tube is caused to dwell between its movements, so that the platinum remains over the flame of the Bunsen burner a sufficient length of time to keep it at an incandescent heat. The tube in its motion passes through a chamber having communication with the exploding chamber of the motor engine, so that the charge is ignited by the incandescent metal. Claims: The use and application of a hollow cylindrical rod, carrying a piece of incandescent platinum, passing through a chamber in communication with a motor cylinder for igniting the charge therein; (2) the use of the above apparatus as a starter for motors.—No. 7533. May 6th, 1889. 6d.

BLOCK FUEL MACHINERY.—*J. Pring, Newport.*—To a pug mill of ordinary construction is fitted a pusher plate having cast in it the moulds for forming the blocks of fuel. The material is fed into the moulds, compressed, and discharged in finished blocks as the pusher plate is reciprocated. In the illustrations, A is a pug mill of any description fitted with a pusher-plate B. The pusher-plate receives a reciprocal motion from the gear shown. Under the pusher-plate is a lever E pivoted at one end F to the framing and at the other end to the piston rod of a cylinder D The cycle of operations is as follows: The mould C is charged whilst under the opening J, and it is then moved farther back until it is under the centre block of metal. Steam or other motive fluid is now admitted to the cylinder D and raises the lever E. A pin G in the lever catches the stamper L and so compresses the charge. The lever E then falls down to a horizontal position, and the pusher-plate is drawn back until the mould is in the position shown in illustrations. Steam is again admitted to the cylinder, and the pin H, catching the stamper L, forces the block of fuel out of the mould. Claims: (1) The combination of a a reciprocating pusher-plate, contained wherein

FIG. 1.



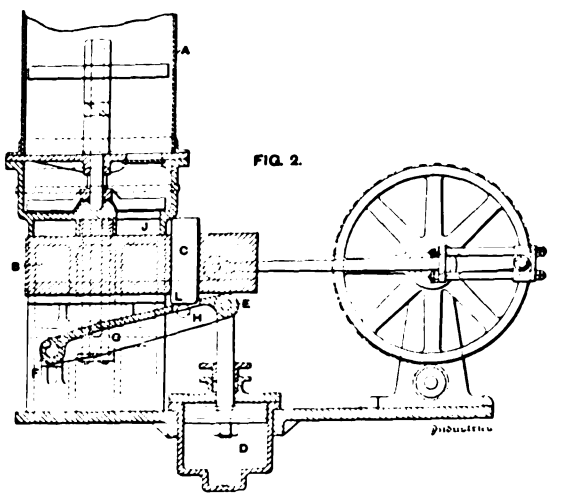


FIG. 2.

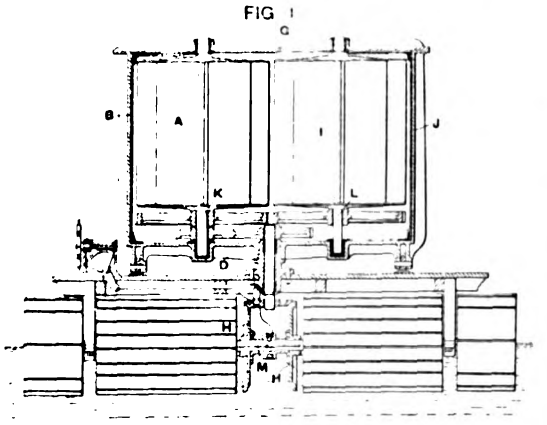
or attached thereto is a mould or recess, and a lever worked by any applicable mechanism, which lever is attached to or connected with, directly or indirectly, a die working into the said mould for the purpose of compressing the material delivered into such mould into blocks or briquettes of patent fuel; (2) the combination of a reciprocating die or plate together with a lever for compressing the material into the said die or mould, as before described, and the utilisation of the same lever for the subsequent discharge from the mould of the pressed block or briquette of patent fuel after such block or briquette has been formed and compressed.—No. 2561. February 13th, 1889. 6d.

CALENDERING APPARATUS.—*T. Pickles & J. H. Pickles, Burnley.*—By these improvements the number of paper rollers in calendering apparatus are reduced. Calendering apparatus as at present constructed have four horizontal rollers or bowls mounted one over the other, two rollers being paper and two metal, so that a metal roller is in contact with a paper roller. As the paper rollers are much more expensive than the metal rollers, the inventor uses one paper and three metal by the following arrangement: Two metal rollers are mounted at the bottom of the machine in the same horizontal plane, but not touching each other. Above these two metal rollers and touching them is mounted a paper roller, and vertically over that a third metal roller. The cloth is passed in at the front of the machine and passes between the paper roller and the two lower metal ones, thence round the paper roller, between it and the top metal roller and over the latter to the back of the machine. Claim: In calendering machines the combination of three metal bowls with one paper or fibrous bowl arranged so that all three metal bowls come in contact with the one paper or fibrous bowl.—No. 6718. April 20th, 1889. 6d.

PROPULSION OF SHIPS.—*T. Parensen, Germany.*—The ships are propelled by wind motors. The system is illustrated in the accompanying drawings, Fig. 1 being an elevation, Fig. 2 a plan. The wind motor comprises a pair of paddle wheels A I secured

FIG. 1



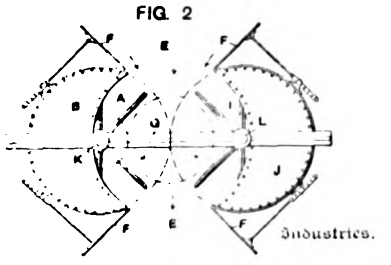


FIG. 2

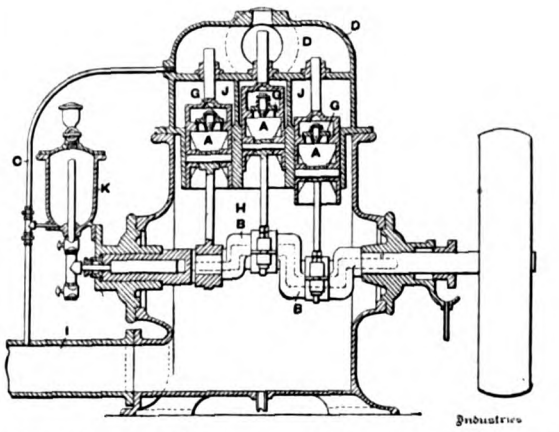
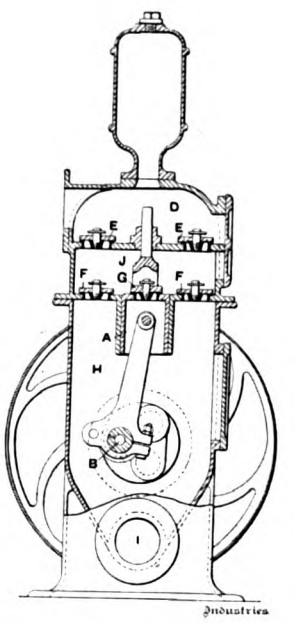
to vertical shafts and partially enclosed in casings B J. The casings B J are provided with deflecting plates F, which guide the wind into the exposed vanes of the wheels A I. The shafts of the wheels A I are geared together by toothed wheels, and that of the wheel A is also geared to the shaft M of the water wheels. The frame of the wind motor is pivoted at its centre, so that the motor can be moved to directly face the wind. For reversing the motion of the vessel the bevelled wheels H are arranged so that one or the other may be put into gear with the driving wheel of the wind motor as required. A number of these motors may be arranged along the deck of the vessel, and their axes, instead of being vertical, may be horizontal. Four claims are made.—No. 6080. April 9th, 1889. 11d.



TRANSMISSION OF ROTARY MOTION.—*A. L. Shepard, London.*—A clutch is here described for transmitting motion from one shaft to a similar shaft in direct line with it. Upon the ends of the two shafts are keyed toothed gear wheels, and beyond these wheels are mounted loosely two discs. Between the gear wheels, and supported by the ends of the shafts, is a pulley, to whose flanges are screwed the two discs. In the pulley and discs is supported a short length of shafting, carrying two other toothed wheels, which gear with those upon the end of the shaftings. The wheels upon the counter-shafting are rigidly secured to it, and are of different diameters to suit the wheels of different diameters upon the ends of the shaftings. Over the pulley is a friction band, by means of which the pulley, and with it the discs, can be held stationary or permitted to revolve at any desired speed. The action of the clutch is as follows:—When the driving shaft revolves, the toothed wheel secured to it, being in gear with one upon the counter-shaft, causes the latter to revolve with the third toothed wheel, which gears with the wheel upon the end of the other shafting. Thus, if the pulley and discs are held stationary, the wheels upon the counter-shaft will cause the shaft to be driven to revolve, but if the pulley is freed the motion of the counter-shaft will cause the pulley to revolve only. By means of the friction band the pulley may be held stationary or permitted to revolve at any speed, thus controlling the rate at which the shafting is driven. Claim: The improved clutch, comprising the drum or casing, and means for arresting or retarding its motion as described.—No. 7350. May 2nd, 1889. 8d.

VENTILATOR.—*W. P. Thompson, Liverpool.* (*H. Krämer, Germany.*)—This ventilator separates from the air the particles of dust contained in it. The apparatus works after the manner of a centrifugal separator. It consists of a fixed and preferably cylindrical channel, through which the air enters, the channel ending in a funnel-shaped opening. In the funnel-shaped prolongation of the channel is placed a fan, firmly fixed upon a revolving shaft whose axis is coincident with the axis of the channel and opening. A drum made of wire gauze surrounds the channel and fan, and is firmly fixed to the revolving shaft, so that the fan and the drum are revolved together. The gauze wire drum is surrounded by a second cylindrical case. The action of the ventilator is as follows:—The air is drawn in through the supply channel and given a rotary motion by the revolution of the fan and the gauze drum, at the same time it is driven back through the annular space between the supply and gauze drum. Since the dust is heavier than the air, the centrifugal action causes the dust to separate and fly to the sides of the gauze drum, passing through its interstices to the case surrounding the drum. The dust, after passing into the surrounding case, falls into a number of collecting boxes which have at their bottoms a corrugated roller for conveying the dust away. Five claims are made.—No. 3846. March 5th, 1889. 8d.

FLEXIBLE BENDS.—*S. Z. de Farranti, London.*—For applying steam to steam engines it is usual to employ tubular mains of copper having bends in them. When the mains are of large size the bends have to be made of parts brazed together, and the strength of the metal is thus often impaired. To remedy this, the inventor makes bends from solid drawn copper tubes, by forming in the tubes a succession of indentations passing nearly round their circumferences, giving the inner part of the bend a corrugated form. These indentations or corrugations are formed in the following manner:—The tube is passed over a vertical mandrel, held rigidly at its lower end, and having a groove partly around its upper end. A roller which fits the groove is caused to roll round the mandrel and squeeze the pipe into the groove. The roller moves round the mandrel in a circle eccentric to the axis of the mandrel, so that the indentation made in the pipe gradually tapers away from its centre. Indentations are made like this all the way up one side of the pipe, causing it to curve upon the indented or corrugated side. Another method is to make the bends of a number of small pipes bent to the required curve and connected to the ends of the straight pipes by caps of suitable construction. The bends may also be made of a number of small pipes stranded together in the manner of rope, the ends being suitably connected to the straight pipes. Seven claims are made for the method described of making pipe bends, and for the apparatus employed in indenting them.—No. 7276. May 1st, 1889. 8d.



MULTIPLEX PLUNGER PUMPS.—*G. E. Dow, San Francisco, California, U.S.A.*—The accompanying illustrations show a longitudinal and transverse sectional elevation of a pump of new construction and combination of parts. The plungers A are three in number to maintain an even balance and pressure. They are

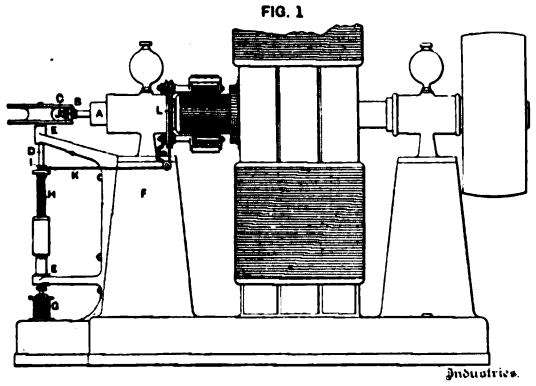
FIG. 1.

hollow and connected to a three-throw crank shaft B at equal angles. The crank shaft is made hollow for the purpose of lubrication, the oil being forced from the lubricator K by fluid under pressure supplied from the discharging chamber D of the pump through the pipe C. A novel arrangement of the valves E, F, and G will be readily understood from the drawings. In the pump

FG. 2.

shown the suction takes place through a chamber H enclosing the crank shaft and its connections. The liquid enters at the opening I, and after passing through the chambers H, J, and D is discharged by the opening M. For pumping dirty or gritty water, the top of H is divided from the lower by a diaphram, and the entrance for the water made in the top part, the lower part being partially filled with oil and water for lubricating the crank shaft, &c. Eight claims are made.—No. 650. January 14th, 1890. 8d.

DUPLEX RUDDERS.—*V. F. Lässoe, Brooklyn, U.S.A.*—This improvement is more especially designed for screw steamers, and particularly for such as have a single screw. Its object is to produce, by changing the relative angular position of two rudders, such divergence of the column of water thrown back by the propeller, that it will flow at such an angle to the line of the keel, as, by its reaction, to turn the vessel sharply, to the extent if desired of turning on its centre of displacement with a force proportionate to the propelling power of the engine. The rudder is constructed



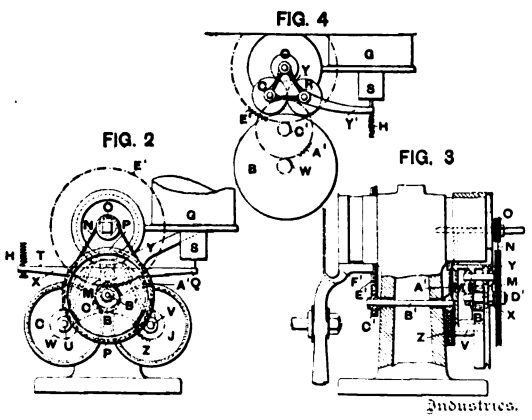
Digitized by Google

with a vertical shaft substantially similar to the rudder stock of an ordinary rudder. This shaft has forged to it two pairs of arms which project from the shaft horizoutally, one pair near the top of the shaft and the other from the bottom. These arms proceed from the shaft at an angle of about 60° to each other and the top pair are situated vertically over the bottom pair. Between these arms are pivoted, near one of their vertical edges, the rudder blades. The rudder blades are also connected at the top near their other vertical edges by rods to a sliding block which has a movement in a direct line with the keel. To the upper part of the vertical shaft is secured a toothed sector which gears with a small toothed pinion whose revolution causes the sliding block to move in one or the other direction along its guide. The vertical shaft is revolved by any of the steering mechanism generally employed. When the rudder blades are normal they are parallel to each other, but by turning the vertical shaft to its extreme position, one blade will be in a place at right angles to the length of the vessel whilst the other will be moved to the right or left as the case may be, and remain parallel to the ship's length. Between the extreme position and the normal the blades gradually tend to assume one or other of these positions. Four claims are made.—No. 1103. January 21st, 1890. 8*d*.

ELECTRICITY.

Controlling Electric Currents.—*C. R. Heap, London.*—A regulating device is fitted to the electric generator and controls the current in the working circuit. In Fig. 1 this device is shown fitted to a dynamo. Upon an extension of the shaft A is mounted a small pulley B. The pulley B revolves between the flanges of a larger pulley C mounted upon a vertical shaft D. The shaft D has a vertical movement and has attached to its lower end the core of a solenoid G which is in the working circuit. A V-grooved pulley I is secured to the shaft D, and carries an endless band K, which passes round the pulley L upon the commutator brush

FIG. 1



shifter. When the current in the working circuit varies from the normal, the core of the solenoid is raised or lowered, and accordingly one of the flanges of the pulley C comes into contact with the small pulley B. The pulley C and shaft D are thus revolved, and by means of the endless band K shifts the commutator brushes so as to increase or decrease the current. In Figs. 2 and 3 a modification is shown. In this case the small pulley B is carried by a three-armed lever X. The pulley B is driven off the dynamo shaft by the band N. The core of the solenoid G is connected to an arm of the lever X, and so causes the pulley B to frictionally gear with one of the wheels C J when the current in the working circuit varies from the normal. The wheels C J

FIG. 4

FIG. 2

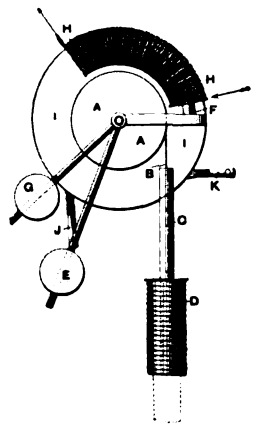
FIG. 3

are geared to the wheel E¹ attached to the brush shifter. A second modification is shown in Fig. 4. The wheel O, which is secured to the shaft of the dynamo, and the wheels Q R are in gear with each other, and consequently always in motion when the dynamo is at work. The wheels Q R are supported by a frame Y, which is itself supported upon the dynamo shaft. By the up and down movement of the solenoid core S the wheels Q and R are put into frictional gear with the wheel B, through which motion is transmitted to the brush shifter. Five claims are made.—No. 6171. April 10th, 1889. 8*d*.

Incandescent Lamps.—*I. A. Timmis, London.*—By this improvement the lamp may be used for two or more purposes; for instance, in lighting railway vehicles the lamp may be used for high candle-power in main lighting and at another time for low power for auxiliary lighting. To do this the inventor constructs the lamp with two filaments of different sizes which will give different candle-power. The higher candle-power filament is used for the main lighting, and the lower one for the auxiliary lighting, thus saving the use of two globes and the use of two sets of lamp fittings. Claim: The use of an incandescent electric lamp which has two or more filaments in it of different candle-power as and for the purpose described.—No. 9537. June 8th, 1889. 6*d*.

Electric Meters.—*G. Hookham, Birmingham.*—The meter is composed essentially of two parts, the first part is a pendulum oscillating isochronously and the second part is a moving part whose position is alternately and at regular intervals first displaced by the current passing and afterwards restored to zero by the action of the pendulum. This last part has its movements recorded by a counting apparatus. In Fig. 1, A is a pulley freely movable about its centre; B is a flexible band from which hangs the core C of a solenoid D; E and G are weights attached rigidly to the pulley A, the one G for the purpose of balancing the core F of a solenoid H. A camel's-hair brush is attached to the arm of E, and a similar brush K is attached to the instrument frame; both are cut obliquely to rest upon the periphery of the wheel I, which is the first wheel of the counting train. The action of the machine is as follows: The current to be measured passes through the wire of the solenoid D, the core C is thus drawn downwards and the weight E lifted. As the weight E rises the brush J grips the surface of the wheel I, and causes it to partially revolve. The distance the weight E is lifted depends upon the force exerted by the solenoid D and consequently the strength of current. At stated intervals a contact actuated by ordinary clockwork completes a shunt current through the fine coil solenoid H. This solenoid is sufficiently powerful to overcome the force exerted by the solenoid D, and so restores the weight E to its former position. The clock afterwards breaks the shunt circuit, and the action described is repeated. Fig. 2 shows a modification in which the counting train is actuated directly by the motion of the pendulum. The weight of the rod G is supported by the rod F and weight E. The rod G is held normally, so that a pin L upon the pendulum just strikes the rod as the pendulum oscillates. If now a current

FIG. 1.



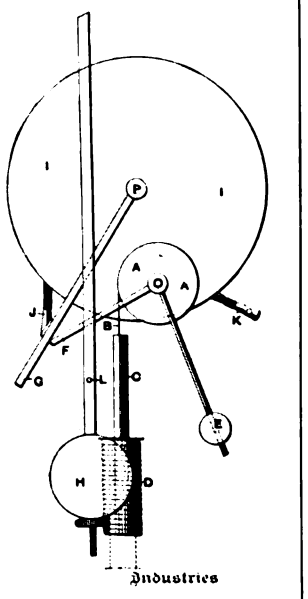


FIG. 2.

passes through the solenoid D the support F lets the lever G drop, and the pin L, in moving it back to zero, rotates the first wheel I of driving train. The stronger the current the more the support F drops and the farther the wheel I is rotated. Claims: (1) The arrangement and combination of parts consisting essentially of an isochronous pendulum or its equivalent and a moving part first displaced from its normal position by the action of the passing current to be measured and afterwards restored directly or indirectly to its normal position by the said pendulum or its equivalent, the said arrangement and combination being used in conjunction with registering or recording mechanism; (2) producing the advance motion and preventing the return motion of the registering or recording mechanism of electricity meters by the employment of camel-hair brushes or other brushes made of natural or artificial fibres arranged so as to act in the manner described; (3) correcting the irregularities of electricity meters caused by excess or defect of the motions communicated to the recording apparatus by the use of a pendulum having a magnetic bob operated upon by a solenoid.—No. 4371. March 13th, 1889. 8*d*.

Electric Firing Fuses.—*H. C. L. Holden, Woolwich.*—The fuse is contained in a double cylindrical case, one part being of larger diameter than the other. An iron core passes through the centre of the two compartments, and it is surrounded in the smaller compartment by a coil of insulated wire, whose ends are connected by a fine wire bridge, which is imbedded in an easily ignitable material. The part of the iron core in the larger cylindrical compartment is surrounded by a second and larger coil of wire. To fire this tube an alternating current of electricity is sent through the larger coil of wire, and by means of the iron core induces an electric current in the smaller coil; this induced current heats the thin wire bridge and ignites the surrounding material. Claim: A tube or fuse containing a closed circuit as described, which is so disposed as regards its electric and magnetic circuit, that an electric current or currents can be induced therein for the purpose of heating the bridge contained therein and thereby firing the tube or fuse.—No. 3761. March 4th, 1889. 6*d*.

Electrodes for Galvanic Batteries.—*F. Marx, Berlin.*—The method of manufacturing metallic electrodes in use up to now consists in working into the required form the metal obtained by a smelting process. The inventor finds that by depositing the metal by electrolysis or precipitation, and using it for the working electrodes, the effect of the electrodes may be considerably increased. The metal deposited as above produces a more powerful current than that produced by smelting. The process of making these electrodes may be understood from the claims: (1) The process of manufacturing metallic electrodes for galvanic batteries by purifying from the presence of salts the metallic deposit obtained by the electrolytic process or by precipitation with other metals, and then working mechanically the mass so purified into the required form; (2) the process of manufacturing metallic electrodes for galvanic batteries by purifying from the presence of salts the metallic deposits obtained by the electrolytic process or by precipitation with other metals, and then rolling into the mass so purified a woven wire fabric or metal plate; (3) the process of manufacturing metallic electrodes for galvanic batteries by electrolytically precipitating, or with metals precipitating, the metal on a conducting plate, then washing the same and fixing it on the plate by rolling.—No. 20217. December 16th, 1889. 4*d*.

CHEMISTRY.

Extraction of Gold and Silver.—*J. A. H. F. Ranft, Sydney, New South Wales.*—According to this invention chlorine is liberated by electrolysis from a common salt solution in contact with the substances containing the gold or silver. This liberated chlorine associates with the metals to form soluble chlorides, which are split up electrolytically as soon as formed, and the chlorine is regenerated for further use whilst the metal is deposited. In

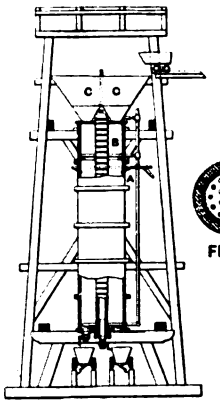

FIG. 1

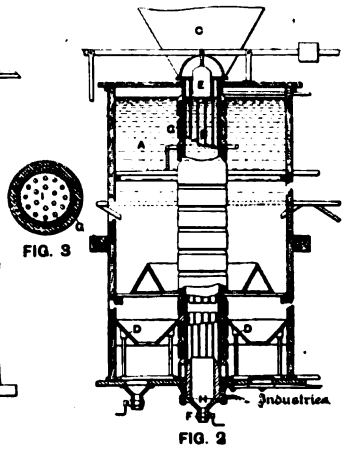

FIG. 3

FIG. 2

the accompanying illustrations of this apparatus Fig. 1 is a side elevation partly in section; Fig. 2, an enlarged side elevation; and Fig. 3, horizontal section. The apparatus principally consists of two cylindrical chambers A and B, between which the material to be treated is fed. Carbon anode plates (not shown) are arranged in the upper part of the outer chamber and metallic cathode plates in the inner chamber. The outer chamber A is constructed of wood, and is provided with charging hoppers C and discharging gates D. The inner vessel is composed of glass segments G fitting one over the other and perforated as shown. These glass segments are supported by a perforated iron tube jacketed by asbestos cloth for the purpose of filtration. The inner chamber is provided with a valve E for the escape of hydrogen gas given off when at work, and a filter H with cock F for drawing off liquor from the chamber. The metal cathodes I (Fig. 3) within this chamber are made preferably of screwed iron rods plated by an incorrodible metal such as platinum. In operation the ore is mixed with the requisite quantity of sodium chloride and fed into the space between the chambers A and B. The chambers are then filled up with water, and the current of electricity passed. The current splits up the sodium chloride and the water into their constituent elements, and the chlorine evolved immediately combines with the gold to form chlorides. Immediately upon formation, these chlorides are split up by the same agency as formed them, and the metallic elements fly to the cathode plates, the gaseous element to the anode. The chlorine formed at the anode quickly combines with fresh metal. The metals deposited at the cathode plates within the inner vessel collect in the form of a sludge, which, whilst being drawn off through the cock F, is partially filtered. When the material has been sufficiently treated, the discharge gates D are opened and fresh material fed in. Ten claims are made.—No. 19944. December 11th, 1889. 8*d*.

MISCELLANEOUS.

Dyeing Yarn in Skeins.—*G. A. Greeven, Crefeld, Germany.*—The process consists in so moving the dyeing liquid as to make the skeins come into contact alternately with the dyeing liquid and air. To obtain this result the skeins are stretched within a reservoir, to which the liquid is admitted by an aperture provided at the lower end. As the liquid is admitted, and its level rises, the skeins are gradually moistened, and when the skeins have become wholly immersed in the liquid the influx is cut off, and after being permitted to act upon the skeins for a sufficient length of time the liquid is gradually let off. The liquid is thus alternately let in and out as many times as is required, and so dyes the yarn uniformly. The apparatus used in this method consists of a trough for the reception of the skeins, and a reservoir situated at a height above the trough for the reception of the dye. The dye reservoir and the trough are in communication by a pipe, which enters the latter near its bottom. The dye liquid is admitted to the trough under pressure of its head, and is drawn back into the reservoir again by means of a pneumatic pump, which removes the air from the reservoir. Two claims are made for the method and apparatus described.—No. 9432. June 7, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. THE INSTITUTION OF NAVAL ARCHITECTS.

(*Continued from page* 341.)

THE paper read by Professor P. Jenkins, on "The Strength of Ships, with Special Reference to the Distribution of Shearing Stress over a Transverse Section," we give in full as follows:—

Eight years ago, when my friend Mr. Read and I read a joint paper on the strength of ships before the Institution, we commented on the fact that this branch of the science of naval architecture had practically remained untouched. The same fact had been previously adverted to by Mr. William John, who in a paper on the same subject spoke of the field for investigation as being "of almost unlimited extent." Since 1882 but little advance has been chronicled. In 1886 Mr. Read read a paper on the strength of bulkheads, in which that most difficult subject was treated with much originality; and in the same year Dr. Elgar opened up a practically unknown branch by discussing before the Royal Society the twisting strains on ships produced by rolling. With the exception of the work of those two papers, no attempt has been made, so far as I am aware, to advance our knowledge of the stresses upon ships during the above period. Probably the neglect which so important a branch of our professional work has suffered is due to the fact that an investigator cannot proceed far without finding that he needs experimental data for the proper prosecution of his inquiry which do not exist, and which cannot be obtained without the expenditure of much time and money. It is probably true, also, as was said by Mr. Rumage at a recent meeting, that the fact that the Register Societies prescribe the scantlings which all classed ships are required to have, and thus practically relieve the shipbuilder of responsibility for their sufficiency, takes away from him the incentive he would otherwise have to find out what the stresses to which sea-going vessels are subject at different parts really are under the worst conditions of loading thought probable, and to arrange the scantlings accordingly. But be this as it may, I think I may fairly say that up to the present time practical experience of the working of ships has been relied upon mainly in the fixing of scantlings. Scantlings have been increased here and there according as the actual straining of ships seemed to warrant. This may appear at first sight to be an excellent plan; it certainly has the merit of being on the safe side. But inspection does not always accurately reveal the true causes of straining. Hidden indifferent workmanship and exceptionally bad stowage have been in some cases the true causes of the straining that has been set down to lightness of scantling. Even if the straining of ships of sea were in all cases accurately diagnosed by surveyors and attributed to its true cause, reliance upon practical experience alone would never enable us to discover in what parts of a ship scantlings may be safely reduced. It is on this point that we chiefly want information. I remember hearing the late William Denny, on more than one occasion at the meetings of this Institution, appeal to our scientific naval architects not to rest content with telling shipbuilders where they should increase the scantlings of their ships, but to go further, and tell them also where the scantlings could with safety be reduced. I do not claim that a thorough investigation of the stresses experienced by ships at sea from all causes under given conditions should be deemed a sufficient substitute for experience of their working in regulating the scantlings, but I do think that such investigations would be of service in enabling the material in the different parts of the hull to be arranged with due regard to the character and amount of the maximum stress it has to bear. It would, moreover, be of advantage in enabling some discrimination to be made between vessels of full and fine form; in fixing the difference in the scantlings which vessels of the same breadth and depth, but differing in length, should have; and in gauging the effect of changes in the breadth of vessels of the same length and depth, as well as in many other ways. While saying that practical experience has been the main guide in the past, I must make an exception as regards the larger classes of vessels, because I know quite well that at Lloyd's Register at least the question of the sufficiency of their longitudinal strength was studied with the greatest care. But even in this, the simplest of all the problems connected with the strength of ships, the assumptions one has to make at the outset in order to render the calculation possible in the present state of our experimental knowledge, is one which makes the deduced stress of doubtful quantitative value, although it is unquestionably of importance for purposes of comparison.

For many years all published calculations of longitudinal bending moment have proceeded on the assumption that the vessel is most strained when crossing waves of her own length, and at the instant when the crest is amidships, the weight and buoyancy being equal. The former assumption is, perhaps, true; I do not, however, admit the latter assumption to be accurate, although I am quite unable at present to say what the extent of the error in the deduced stress really is. The fact that the calculation of longitudinal bending moments has proceeded for so long a time, on the assumption that the maximum is attained when the vessel is placed on the crest of a wave of her own length, the weight and buoyancy being equal, is due, I think, to the circumstance that, for the largest classes of vessels, the results obtained have appeared to give about the maximum stresses the material could repeatedly withstand without becoming distressed, and as in some of the larger vessels signs of straining at the topsides have not been wanting, this has been taken as a practical confirmation of the truth of the assumptions on which the calculations were based. But Mr. Smith's paper of 1883 showed very clearly that if the variation of the law of pressure within the wave structure from that holding in still water be taken account of, as to a certain extent it undoubtedly should, the maximum stresses obtained from the calculation become reduced to a limit below that which may be expected to cause distress in the material of the hull. Another fact which has led me for some time to regard with suspicion the usual theory adopted in the calculation of longitudinal stresses is the smallness of the deduced maximum stresses for little vessels. These, as calculated, do not, in some instances, amount to more than two tons per square inch for sea-going vessels, and I think it absurd to suppose that intelligent practical men would go on, year after year, building these vessels with such an enormous excess of longitudinal strength as they must have if the results of this calculation are to be relied on. On the ground, then, of the disparity existing between practice and the results of this method of calculation, I think we are entitled to regard it with some doubt. But I think I may show in a few words that the assumption on which the calculation is based is in error, in some cases at least, to a considerable extent. If a vessel be supposed to cross a series of regular waves of her own length at right angles to the line of crests, while considerable changes of trim will occur, she will be lifted bodily as she is embraced by an advancing crest, and will fall bodily as the trough of the wave approaches amidships. She will, in fact, perform a series of dipping oscillations somewhat similar in character to what takes place if a body floating in still water be forced down into it beyond the normal draught, and be made to continue the dipping oscillations by a succession of impulses. Now the rise or fall of the vessel's centre of gravity during the passage of the waves is necessarily conformable to the common law, viz.—Acceleration = (Moving force) Mass moved, the upward pressure of the water being at the same time employed in causing this acceleration and in changing the trim. Thus if, in Fig. 1, P be the resultant upward pressure of the surrounding fluid at any instant, and A its point of application, while G is the centre of gravity through which the weight W acts, we may suppose two equal and opposite forces P applied at G as shown. The difference P — W at G will be the moving force of the above equation, leaving the two other forces P to form a couple P*a* which has effect in changing the vessel's trim. So long, therefore, as the total upward pressure of the water surrounding the vessel is greater than the weight, the upward velocity is being accelerated, and when P is less than W there is an acceleration downward.

FIG. 1

Let us now glance at what must be a very common case. Assume that the vessel's centre of gravity is moving downward as the trough passes amidships. With the advance of the next crest the downward velocity is gradually destroyed, and the centre of gravity begins to move upward. This change in the velocity will not take place until the crest has advanced from the bow some distance along the side, and the velocity downward can only be destroyed by an excess of buoyancy over weight causing an upward acceleration. The vessel then begins to rise under the influence of an excess of fluid pressure. Commonly the total upward pressure of the water will be still greater than the weight of the vessel when the crest of the wave reaches amidships, and as this must have been the case from the instant the velocity downward began to decrease, the upward velocity with the crest amidships must be greater than at any previous instant during the lifting of the vessel. Moreover, the velocity upward will continue to grow as the crest passes abaft amidships until the instant at which the weight and the upward pressure become equal. After that instant the velocity upward is retarded, because the mass moved is greater than the lifting force, and the acceleration is downward. Hence we see that in the case I have taken, instead of the vessel being at rest on the wave when the crest is amidships with the weight and buoyancy equal, she does not come to a state of rest until some little time after the crest has passed the middle of the length, and that at the instant at which she does come to rest the supporting force is a great deal less than the weight. Obviously the motion I have here traced out is not representative of the behaviour of the

BISCUIT MAKING MACHINERY.

Digitized by Google

vessel on every wave of a series. Her behaviour on each wave will be different usually from that on the preceding wave, and will depend on the period of the wave, and on her dipping period. It might at first sight be thought that with the vessel raised on the wave at a greater height than that corresponding with the position of statical equilibrium, the bending moment amidships will be greatly increased, but this is not necessarily the case—it might be greater or it might even be less. By way of illustration, imagine a prism of rectangular section to be in statical equilibrium on the crest of a wave of its own length. Assume it to be homogeneous, and assume that the calculation of the longitudinal bending moment amidships is made in the usual way. If now the prism be supposed on the wave at a lighter draught than that corresponding with the position of statical equilibrium, or at a deeper draught, no change takes place in the value of the bending moment as calculated, if the variation of the pressure in the wave from that holding in still water be neglected; it is the same for all three positions of the prism. If, however, the prism be not homogeneous, having more weight in the ends than in the middle, the bending moment is greater when it is immersed in the wave to a greater extent than that corresponding with the position of statical equilibrium than it is for the statical position, and less when it is immersed to a less extent. If, on the other hand, the weight in the prism be greater in the middle than towards the ends, the converse takes place: the bending moment is greater when the prism is elevated above the position corresponding with statical equilibrium than it is for that position, and less when it is immersed to a greater extent. In the case of an actual vessel elevated on a wave above the position of statical equilibrium, if the centre of gravity of the hull and cargo in, say, the fore body, be before the centre of buoyancy of the layer in the fore body enclosed between the actual water surface and that corresponding with the statical equilibrium, the bending moment amidships is less than that corresponding with the position of statical equilibrium, and greater if the converse be the case. If the vessel be immersed when on the crest to an extent beyond that corresponding with statical equilibrium, as may sometimes be the case, the bending moment amidships will be increased, if the centre of buoyancy of the layer in the fore body enclosed between the actual water surface and that corresponding with the position of statical equilibrium is abaft the centre of gravity of hull and cargo in the fore body, and decreased if the converse be the case. What the precise difference between the greatest bending moment and that calculated on the usual assumption would be in any given case, it is impossible to say without actually tracing the vessel's motion as she crosses the waves, and that cannot be done without data as to the resistance to the motion of a variety of ship-shaped sections downward through the water with different velocities. It is important, however, to observe that the actual maximum bending moment amidships must be greater than that corresponding with the position of statical equilibrium, because if it be less when the vessel is elevated above that position it must be greater when she is below it, and *vice versâ*.

In the foregoing remarks no note has been taken of the effect upon the bending moment of the changes in the trim which occur as the wave passes the vessel. Referring again to Fig. 1, it will be seen that so long as the point A is on the fore side of the centre of gravity, the moment to change trim will have the effect of raising the bow and depressing the stern, and that this will continue with growing angular velocity until A and G are in the same vertical—that is to say, when the crest of the wave is about amidships. The angular velocity of the bow upward has then its maximum value, and when A passes abaft amidships the moment to change trim first destroys the angular velocity and then changes its sign. The effect of this angular motion upon the bending moment amidships depends upon the distribution of the weight in the fore and after bodies. If the moments of inertia of the fore and after bodies about a transverse axis through the centre of gravity be equal, then, if the vessel be out of trim when on the crest of a wave, the bending moment amidships is unaffected thereby. If, however, they be unequal, and they may in practice differ appreciably, the bending moment amidships is decreased when the moment of inertia of the fore body is greater than that of the after body, if the trimming moment tends to depress the bow and raise the stern, and increased if the moment of inertia of the after body be greater than that of the fore body. I have already shown that the bending moment amidships is necessarily greater on some waves of a series than that calculated for the position of statical equilibrium, and we now see that it may be further augmented by the pitching and 'scending of the vessel.

I have been led to make this imperfect sketch of the behaviour of a ship on a wave because the shearing force over a transverse section which I propose now to discuss is similarly affected with the bending moment. Like as regards the maximum longitudinal bending moment, the practice has been to calculate the maximum shearing force for the case in which the vessel is in statical equilibrium on the crest of a wave of her own length. But I have shown that at some time, in crossing a series of regular waves of her own length, the bending moment amidships must be greater than that corresponding with the position of statical equilibrium, and that with a common distribution of cargo it may be further augmented by pitching and 'scending; and since the bending moment at any point of the length is the area of the curve of shearing force between either end of the vessel and that point, it will be seen that augmentation of the bending moment necessarily involves an increase in the shearing force. As with the bending moment, I am not able to place a quantitative value upon this excess. Bearing in mind the fact, however, that the maximum shearing force will be frequently greater than that calculated in the usual way, I will now turn to the problem which has given the title to this paper—viz., that of the distribution of shearing stress over the transverse section of a vessel.

I have long been impressed with the fact that most vessels that exhibit symptoms of straining under water do so at the upper turn of the bilge. Now, so far as the stresses due to longitudinal bending moment are concerned, we know that the distressed parts, being near the neutral axis, can be subject to but very little stress from that cause, and the question arises as to the origin of the sometimes severe straining at that part. No doubt the stress due to the transverse bending moment must be considerable near the place where the floor plate ends, especially when a heavily laden and badly stowed vessel is rolling heavily; and this may in some circumstances be a factor in causing the distress referred to, but I believe it is helped appreciably by the shearing stress the material has also to bear at that part. To make clear what I have to say regarding this particular form of stress, it will be necessary to show how the distribution of shearing stress over a section in the case of a body subject to bending moment differs from that in the case of a section subject of shearing force alone. If two equal and opposite forces F be applied at the section of any bar, as in Fig. 2, the whole shearing force over the section is F, and probably the intensity of the shearing stress per square inch of the material will be nearly uniform throughout, except in the immediate neighbourhood of the places of application of the forces. But if a beam be weighted with a load W, as in Fig. 3, while the total shearing force over any section is W, the shearing stress is not uniformly distributed over the section as in the previous case, but is greatest at the neutral axis, and nil at the top and bottom. The excess of the maximum shearing stress over the mean depends greatly upon the arrangement of the material in the section. The fact that the shearing stress is not uniform over the section in the case illustrated by Fig. 3 has long been known to authorities on the strength of materials. I find that Rankine mentions it in his great work on shipbuilding, and gives a

FIG. 2

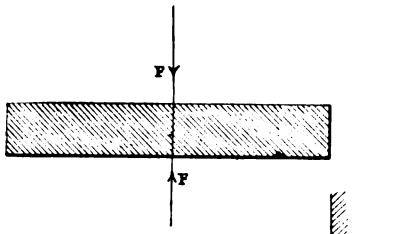

FIG. 3.

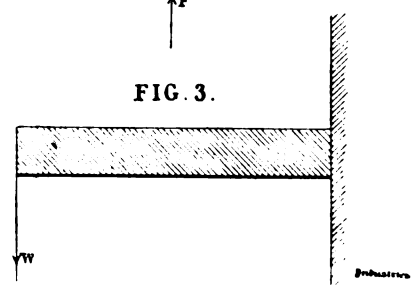

FIG. 4.

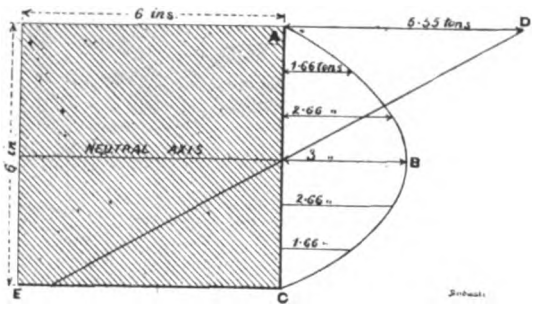

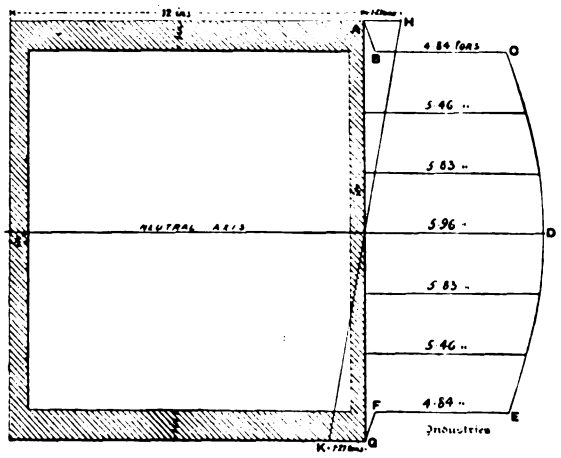

FIG. 5.

rule for determining it at each point of a section in any given case, but I do not think he, at that time, attached to it so much importance as it deserves, and I am not aware that an actual diagram of shearing stress has been at any time made for a ship. I have had the opportunity recently of making a calculation of the varying shearing stress borne by a transverse section of an actual vessel; but before I refer more fully to it, I should like to call attention to some diagrams of shearing stress for one or two sections of simpler form, subject to shearing force in the same way as the bar of Fig. 3. Fig. 4 is a reduced section of a bar 6in. square, subject to a shearing force of 72 tons. This, if uniformly distributed, would give a mean of 2 tons per square inch. The actual distribution of the shearing stress is given by the ordinate from A C to the curved line A B C at the side of the diagram, being 3 tons at the neutral axis, and nothing at the top and bottom. If the bending moment borne at the section be, say, 200 foot tons, the distribution of the stress due to it is represented by the ordinate, from A C to the straight line D E, being 5·55 tons per square inch at the top and bottom of the section, and nil at the neutral axis. Hence we see that the shearing stress is a maximum where the stress due to longitudinal bending moment is nil, and nil where the stress due to the longitudinal bending moment is a maximum.

Consider next the hollow girder shown in Fig. 5, having heavy flanges at the top and bottom. The sectional area is the same as that of the square bar of Fig. 4, and if the total shearing force over the section be assumed to be the same, viz., 72 tons, the mean shearing stress will be two tons per square inch as before, but the maximum will be increased to 5·96 tons per square inch. The actual distribution of the shearing stress is shown at the side by the curve A B C D E F G, the maximum of 5·96 tons being, as before, at the neutral axis. The ratio of the maximum to the mean is here 2·98, whereas in the case of the section of Fig. 4 it is only 1·5. If this girder of Fig. 5 be subject to the same bending moment as that of Fig. 4—viz., 200 foot tons, the distribution of stress due to it is represented at any place by the ordinate from A G to the straight line H K, being but 1·21 tons per square inch at the top and bottom of the section, and nil as before at the neutral axis. While the effect, therefore, of massing the material at the top and bottom of the girder is to reduce the maximum stress due to longitudinal bending moment in the examples given from 5·55 tons per square inch to 1·21 tons per square inch, it augments the maximum stress due to the shearing force from 3 tons per square inch to 5·96 tons per square inch, and if this were carried sufficiently far the girder would break down through the yielding of the sides under the influence of the shearing stress alone.

Although the causes of the variation in the shearing stress over the section of a girder are discussed in some advanced works, it will make this paper more complete if I allude briefly to them here in connection with the case of an actual vessel. Let A B and C D, Fig. 7, be two transverse sections of a vessel near to each other, N N being the neutral axis, and let M_1 be the bending moment borne by the section A B when the vessel is on a wave, and M_2 that similarly borne by C D. Assume the two sections to be so near each other that differences arising out of change of form and sheer may be neglected. The longitudinal stress per square inch at the gunwale A will be found by the well-known equation $p_1/y = M_1/I$, and that at C by the equation $p_2/y = M_2/I$, and if M_2 be greater than M_1, p_2 will be greater than p_1. We shall thus have, if we consider a small strip of sectional area a between A and C, a force $p_2\ a$ acting at the one end, and a smaller force $p_1\ a$ at the other. Under the influence of the unbalanced force $(p_2 - p_1)\ a$ the strip tends to move in the direction from A to C, and the resistance to this tendency is provided by a shearing force along the lower edge of the strip A C. If now we examine the case of a similar strip of section a nearer the neutral axis than A C, p_3 and p_4 being the longitudinal stresses per square inch calculated as above, we shall have similarly a resultant force $(p_4 - p_3)\ a$ on the strip which causes shearing stress along its lower edge, as already explained. It will be seen that the shearing effect of all these differences of stress is cumulative as we pass from the gunwale towards the neutral axis, so that the magnitude of the longitudinal shearing force is greater there than at any point nearer the gunwale. If now we regard the part of the vessel below the neutral axis, we shall have on a strip at D B of section a a compressive stress $q_1\ a$ at the one end, and $q_2\ a$ at the other. Their difference $(q_2 - q_1)\ a$ must be resisted as before by the shearing stress along the upper edge of the strip. The same holds true of any other strip we may select below the neutral axis, and the sum of all such small quantities similar to $(q_2 - q_1)\ a$ below the neutral axis must be the same as the sum of all such small quantities as $(p_2 - p_1)\ a$ above the neutral axis, either of which is the longitudinal shearing force on the plating at N N. In the same way the longitudinal shearing force at any place between N N and the gunwale, or between N N and the keel, may be found by taking the algebraic sum of all these small differences of longitudinal stress between that place and either the gunwale or the keel. The actual longitudinal stress per square inch of the material at any place may now be found by dividing the ascertained shearing force by the sectional area at that place between the sections A B and C D. Having found the longitudinal shearing stress at any place, we may at once obtain the shearing stress at the same place across the transverse section from the fact that shearing stress along any plane must be accompanied by shearing stress of equal intensity along a plane at right angles to it. Hence we see that the longitudinal shearing stress which has been shown to exist in the plating at any place generates equal shearing stress over the transverse section at that place. Briefly stated, the shearing stress per square inch at any point of a transverse section of a vessel may be found by dividing the product of the actual shearing force borne at the section and the moment of the area of the section above the given point about the neutral axis by the product of the moment of inertia of the whole section and twice the thickness of the plating at the given point. It will be obvious, from the above rule, that the maximum shearing stress in a vessel will usually occur in the transverse section at which the shearing force is a maximum.

I have constructed a diagram of shearing stress for a vessel, for which Mr. John Inglis has very kindly supplied me with the necessary data. The vessel in question is 330ft. long, and Mr. Inglis has had curves of shearing force and bending moment drawn for her, as actually laden, on the assumption that she was in statical equilibrium on a wave of her own length, and 20ft. high. The maximum shearing force in this case is 1,233 tons, and occurs at a section 93ft. abaft the stem. Fig. 6 is the transverse section of the vessel at that place, modified somewhat to conform with the usual style of construction, and by the side of it is shown the actual diagram of shearing stress. It will be seen to be a very irregular curve. Starting from zero, at the top of the section, the shearing stress per square inch grows regularly in intensity until the upper deck is reached. Here it becomes reduced again to a very small amount, since the thickness of the deck, measured horizontally, as it has to be for the estimate for shearing stress, is large. Starting again, below the upper deck the shearing stress becomes at once of appreciable magnitude, because, owing to the large amount of plating upon the deck, the difference of longitudinal shearing force over the small vertical interval occupied by the deck becomes large, and the shearing stress thus induced has to be borne by the sheerstrake just below it. The same feature will be noticed in the diagram of shearing stress in Fig. 5 at the inside of the top and bottom flanges. The curve again begins to grow regularly until the lower edge of the sheerstrake is reached. The sheerstrake, which is fourteen-twentieths of an inch thick, is here attached to an eight-twentieth of an inch between-deck strake, and as the actual intensity of the shearing stress is inversely as the thickness of the plate its value in passing from the one plate to the other

Digitized by Google

is increased to fourteen-eighths its former amount. On reaching the main shearstrake, which is fifteen-twentieths of an inch thick, the shearing stress, for the reason already given, becomes reduced, and is again very small in way of the middle deck, but increases suddenly as soon as that deck is passed. If below the middle deck the plating were of uniform thickness, the curve would be of practically fair form down to the neutral axis, but as it is gradually reduced in thickness in this instance until the neutral axis is reached, the curve continues irregular, there being a point of discontinuity at each lap. At the height of the neutral axis itself the shearing stress is 3·9 tons per square inch. This figure, which is the maximum, has been deduced from the shearing force of 1,233 tons, obtained on the assumption that the vessel is momentarily in statical equilibrium on the crest of the given wave. Below the neutral axis, the diagram takes the form shown, and there will be no difficulty experienced in tracing out the causes of the irregularities in the curve. I may add, that in the calculation the keelsons have been assumed of equal value with the other parts of the hull as regards this particular kind of stress. This can hardly be the case, but it is very difficult to discover the precise kind of action that really takes place at those parts. In referring earlier in this paper to the straining sometimes observed at the turn of the bilge, I ventured the opinion that this may be caused mainly by the shearing stress borne by the material. It will be seen from Fig. 5 that the value of the shearing stress is not appreciably diminished at that place; and, indeed, if the vessel be inclined when on the wave, the angular movement of the neutral axis which takes place, as I explained in my paper of two years ago, will cause it to pass very nearly through one of the bilges, and thus render the latter subject to the maximum stress. It will be obvious, if we look at the form of the section of the plate at the turn of the bilge, that the shearing force upon it between the frames at a butt will tend to change the curvature, and thus lead to the working, the effect of which is so often visible. If I am correct in my view, a very efficient cure for this form of distress would be the fitting of a tee bar on the inside of the butt-strap along the line of the butt. We may draw one or two important lessons from this diagram of shearing stress. In the first place, while the estimate of longitudinal stress shows that stress to be greatest at the top and bottom of the section, and nil at the neutral axis, and that, therefore, so far as that particular kind of straining is concerned, the girder may be strengthened by removing material from the neighbourhood of the neutral axis and massing it at the top and bottom, the effect upon the intensity of the shearing stress at the neutral axis will be of the contrary character. By way of illustration, suppose the strake of plating in way of the neutral axis, which is in this case eleven-twentieths of an inch, were to be reduced in thickness to seven-twentieths of an inch, the difference being applied at the top and bottom of the section. The increase in the moment of inertia of the section would cause the longitudinal stresses to be correspondingly reduced under the given bending moment, but the shearing stress at the neutral axis would be increased from 3·9 tons to nearly $\frac{11 \times 3{\cdot}9}{7} = 6{\cdot}1$ tons per square inch.

Another important difference in regard to the two kinds of stress is to be found in the effect of variations in the thickness of the plating upon their intensities. I have shown above that the intensity of the shearing stress at any place is inversely as the thickness of the plating at that place; on the other hand, as is well known, the stress due to longitudinal bending moment at any place is independent of the thickness at that place, being the same per square inch upon a fourteen-twentieth of an inch plate as upon an eight-twentieth of an inch plate at their place of junction. It is this fact which makes it possible to fit light erections on the upper decks of ships, where the stress due to longitudinal bending moment is a maximum, whereas the employment of such thin material in the neighbourhood of the neutral axis, where the stress due to longitudinal bending moment is nil, would be attended with great danger, owing to the rapid growth of the intensity of the shearing stress.

One other point of some importance in considering the relative values of shearing and tensile or compressive stresses is the fact that the shearing strength of steel is much less than the tensile strength. According to some very careful experiments conducted by Professor Kennedy a few years ago, steel having a tensile strength of 28·45 tons, which is about the tenacity of that used for shipbuilding, was found to shear under the much lower stress of 23·09 tons. It is of interest to note, further, that the greatest shearing stress is probably never experienced amidships; certainly the maximum shearing stress and the maximum tensile stress never occur on the same section. The former must always occur at the place where the curve of bending moment is growing most rapidly, while the latter is at the section at which the bending moment has its maximum value. I have explained how the varying shearing stress actually experienced over a transverse section of a vessel is induced in the material by the tendency which it has to shear longitudinally, and it will be of interest to measure the effect of this longitudinal shearing stress upon the rivets in the landing edges. In the old wooden ships with no edge connection the effect of the longitudinal shearing stress would be to give the adjacent strakes of planking a tendency to slide past each other. Rankine remarked this tendency, and attributed the "spewing" of the oakum from the seams to it. Members present who have experience of wooden ships may perhaps be able to tell us whether the tendency to spew the oakum has been observed to be greatest at the upper turn of the bilge, and at about one-fourth of the length from each end. In an iron or steel vessel the actual longitudinal shearing stress experienced along the lower edge of one strake of plating has to be communicated from it to the strake below through the rivets in the landing edge. The latter are thus placed under shearing stress. We may give a numerical value to this stress in the case of the vessel before us. The total longitudinal shearing force on the plating for a length of one frame space in the neighbourhood of the neutral axis is 24 × eleven-twentieths × 3·9 = 51·5 tons, and the rivets in the landing edge are arranged as in Fig. 8. They are seven-eighths of an inch in diameter, and assuming the stress in each rivet to be the same, this would give 4 tons per rivet, or 6·7 tons per square inch of rivet area. Of course, if any appreciable yielding were to take place under this stress, the framing would be called into play to help resist it.

The above investigation throws some light upon the problem of the riveting of the laps of the plating. So far as tensile or compressive stresses due to longitudinal bending moment are concerned, double-riveted landing edges are not necessary anywhere; the additional material required for the second row could be more beneficially applied in thickening the plates themselves. As regards transverse bending moments, I think that the nature of the girder formed of the frame, reverse bar, and plating is such that the tensile or compressive stress due to this cause can never be so great in the plating as to require double-riveted landing edges. I have shown, however, that the rivets in even double-riveted laps for the case I have taken are under considerable stress in the neighbourhood of the neutral axis at certain parts of the vessel's length. In that part, therefore, double-riveted landing edges in vessels of any size are very desirable. But away from the neutral axis, towards the upper and lower parts of the section, the necessity for double-riveted landing edges is not so apparent; and so far as the work the rivets have to do is concerned, the edges may well be single-riveted. On the other hand, there are objections to the carrying out of this deduction in practice with large vessels. It must be recognised that double-riveted landing edges help to give rigidity to the structure, and assist in keeping the plating to its work. It would, moreover, be found difficult in practice, probably, to properly close the landing edges of thick plates if they were only single-riveted.

THE STRENGTH OF SHIPS.

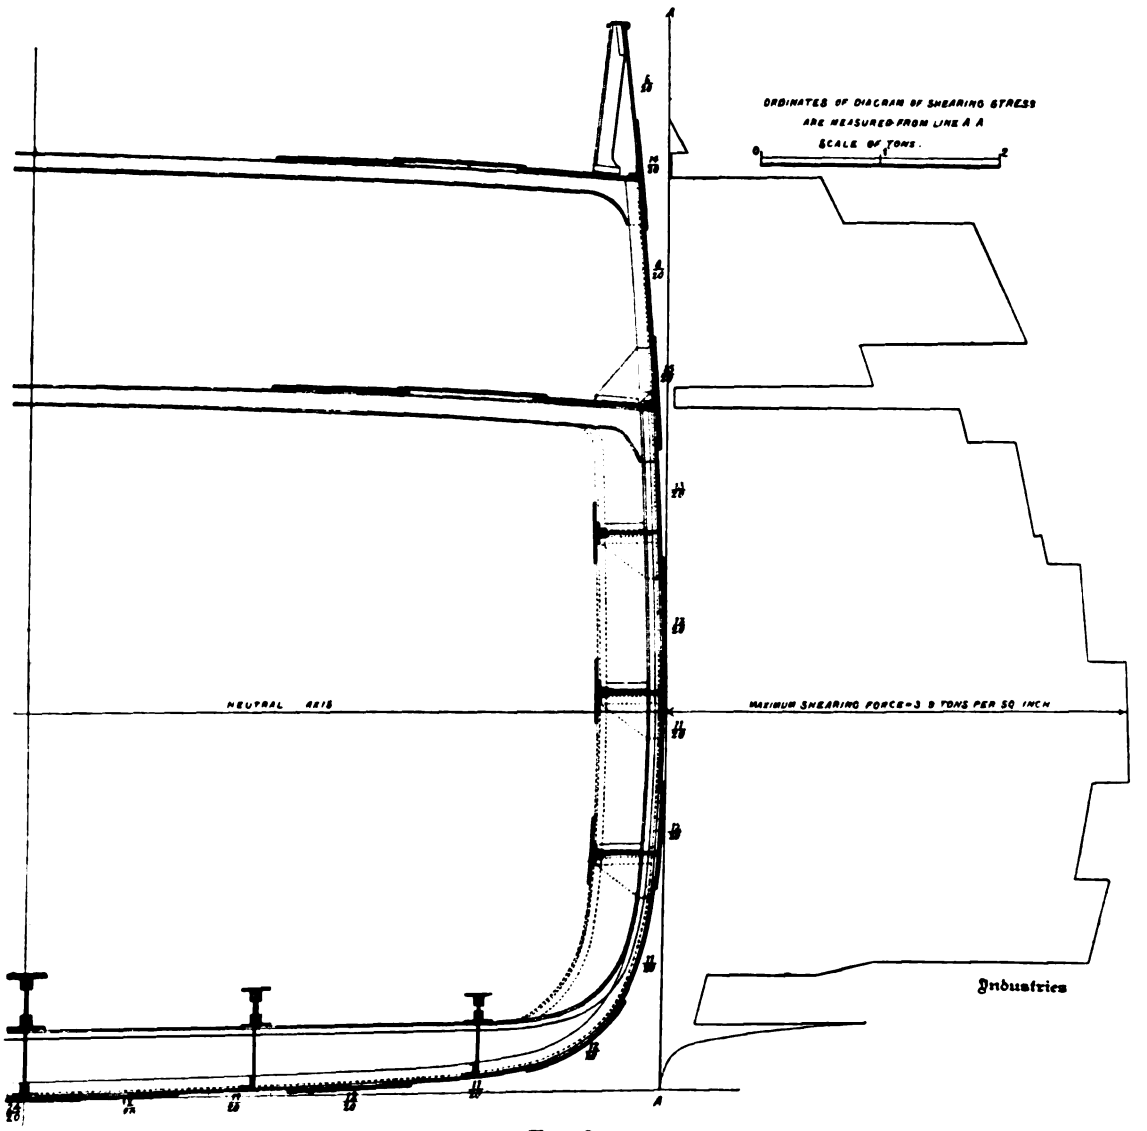

FIG. 6.

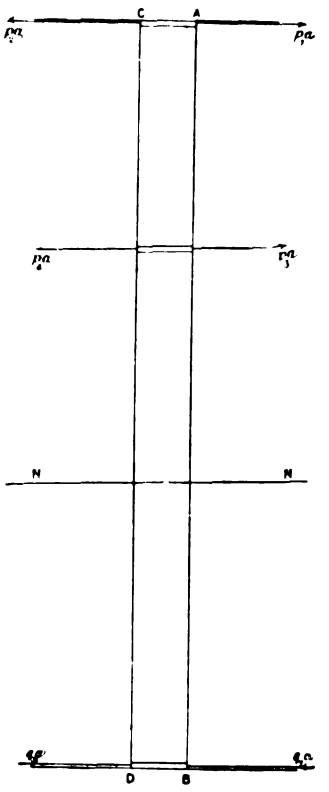

FIG. 7.

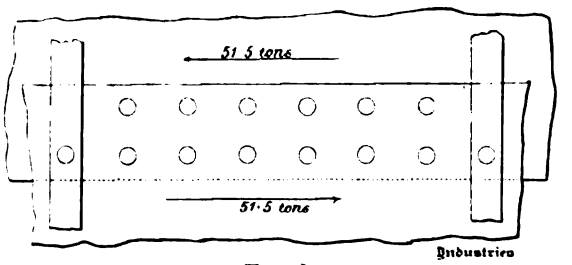

FIG. 8.

The discussion was opened by Mr. Ellis, who said they appeared to be gradually approaching a proper appreciation of the strains to which our ships were liable, and Professor Jenkins had now given them the strain, not on a ship in dock, but when on the crest of a wave. These results had long been known qualitatively, but up to the present time no quantitative results had been given. The deductions had astonished him. The great merit of the paper was in the adaptation of theory to practice. He had previously thought the shearing stress would amount to 3 tons per square inch only, and did not expect the decks would offer any resistance.

Mr. C. E. Stromeyer in answer to Professor Jenkins' requests for further experiments, said that no engineers had followed himself in the results which he laid before the Institution some years ago, but that bridge builders had availed themselves of his idea. He did not agree that

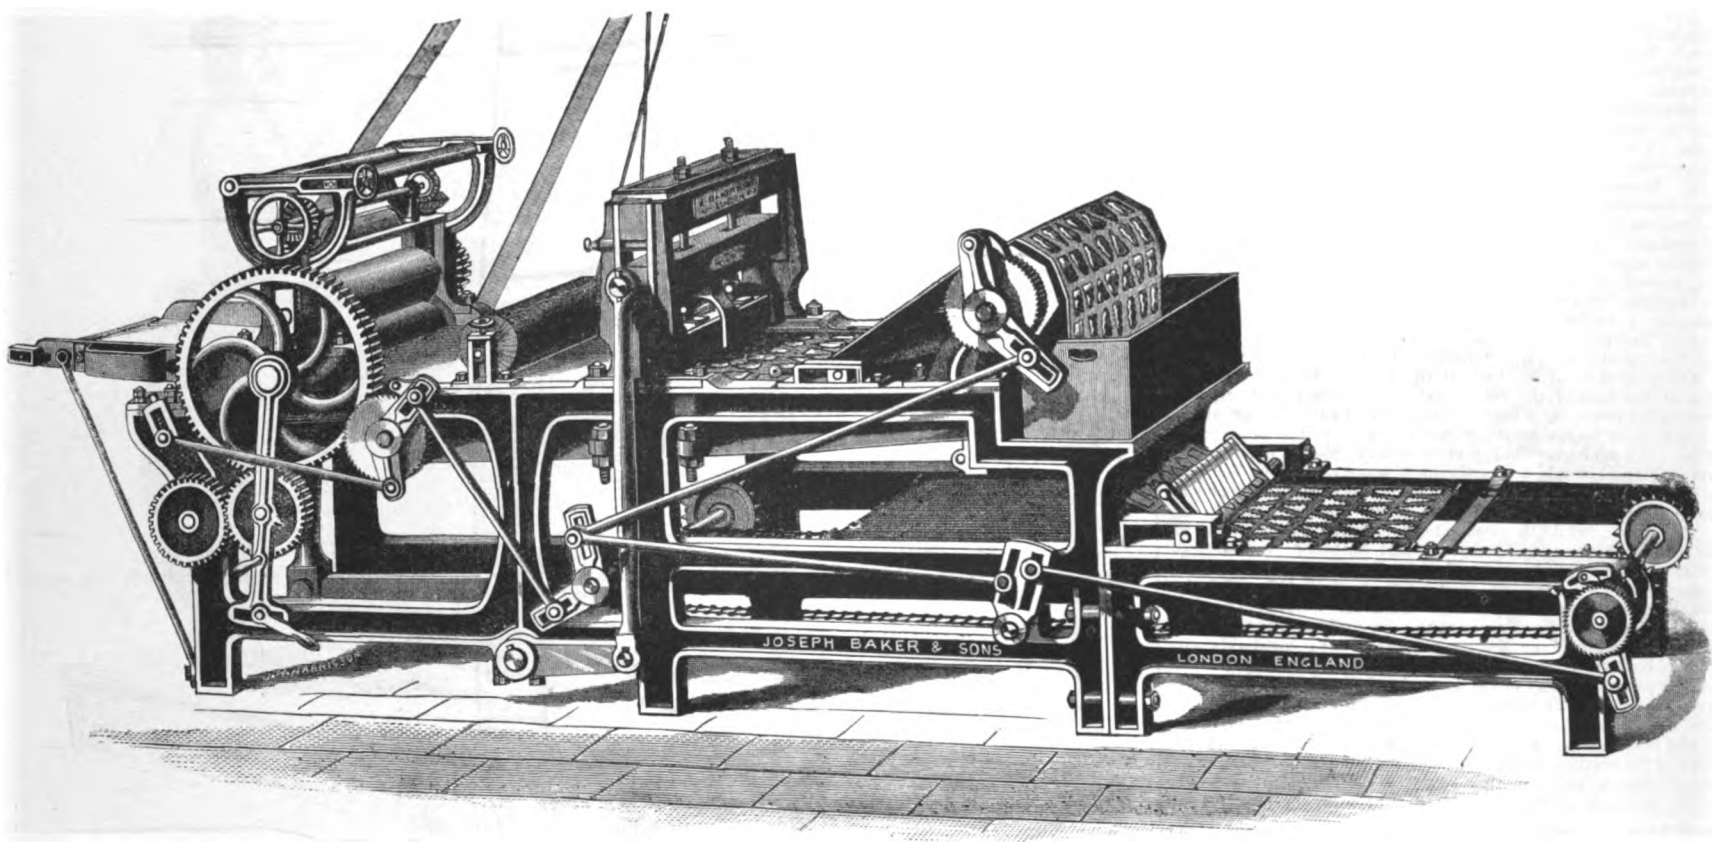

FIG. 2.—BISCUIT GAUGING, CUTTING, AND FRAMING MACHINE.

the decks were subjected to shearing stresses at all, or any other of the horizontal members, and in his opinion the vertical members only bore it.

Mr. McFarlane Gray was of the opinion that many points were left obscure. It was difficult to arrive at the nature of the stresses mentioned.

Dr. Elgar said the paper gave an explanation of many points which had often puzzled him in dealing practically with the strains on ships. The important point of the paper appeared to be the fact that the tensile stresses were not always the chief stresses.

Mr. Biles said the question of the calculation of the strains in a ship was a difficult one, because it was not an exact science. He thought that with small ships the scantlings should be calculated as for large ships. No signs of weakness had been discovered where this had been done in the Navy. He had seen many large steamers in dock which showed signs of straining at the neutral axis, and not elsewhere. This bore out the conclusions arrived at in the paper.

Mr. Martell thought a great service had been rendered to the Institution. Light was thrown upon a subject that had previously been very much in the dark. To those who had to frame rules by which ships should be built it was very advantageous to have the results of such investigations as these. He thought that in the neighbourhood of the neutral axis, the large strains observed were not longitudinal but transverse. Practical men had always remedied this state of things with a double strake, without knowing why they did so. As regards small ships it should be remembered that they had a different duty demanded of them. They were usually employed in going in and out of rivers where they had frequently to take the ground. The matter of wear and tear occasioned thereby had to be taken into consideration, and the scantlings increased accordingly.

Mr. W. H. White agreed with what had been said respecting the paper, but thought the deductions were not altogether new. Twenty years ago Mr. W. John and he had got out diagrams showing the stresses in wooden ships, and the results of their inquiries were mentioned by Sir E. Reed, though not actually published. It was not thought then that iron ships suffered in the same way. Their plan was to thicken the planking at the wales, and use dowelling largely. In bringing forward such quantitative results Professor Jenkins had done the Institution and the shipbuilding industry of the country very great service.

Mr. John confirmed what Mr. White had said as to their joint investigations in connection with wooden ships. If anyone had asked him the value of the maximum shearing stress on a ship of this kind, he would certainly have put it at a lower figure than that quoted in the paper.

Professor Jenkins then replied. He thought Mr. Stromeyer had failed to grasp his meaning as regards including the decks when calculating the shearing stress. He thought, after a long consideration of the question, that the decks did contribute a resistance, as his diagram indicated. He knew that heavier bottoms were required for small vessels to enable them to take the ground, but this ought not to apply also to other parts of such vessels. As to the investigations of the shearing stress upon wooden vessels, he did not consider the two cases the same, as the planks were without any edge connection between them. The longitudinal shearing stresses set up would therefore be very different.

The last paper read on Thursday, the 27th ult., was by Mr. A. Rigg, on his "Revolving Engine as applied on Shipboard." This engine has been before the engineering public for some years now, and, therefore, it is unnecessary to describe it further at present. Mr. Rigg is now engaged in fitting some large engines of this type in river boats on the Thames. An illustration of the application of Mr. Rigg's engines to the launch "Deva" is given in our issue of the 31st of August, 1888.

In the discussion which followed, Mr. A. B. Brown said he had been trying experiments with an engine built on similar lines. In his engine the cylinders revolved. He could never get it adopted on board ship, because of the difficulty of lubrication, and because of the tendency of the oil to get into the boilers. He had some success, however, with water lubrication and roller bearings. He thought the relative reciprocation in Mr. Rigg's engines disturbed the balance of the engine, and he considered that it would be wasteful when cutting off at $\frac{1}{2}$ stroke. He should like to know how the faces of the valves wore, for he had had difficulty with them; and he had substituted eccentric valves for concentric ones, as the latter became badly worn.

Mr. Bevis said he had attended a trial of one of these engines, and found it worked satisfactorily. He was much struck by its simplicity.

Mr. McFarlane Gray said he had seen one of these engines. It was ingeniously arranged, and worked better than he could have expected. When he was a young man he had been employed to work out the details of a revolving engine of this kind. The engine was put into a steamer, and one or two voyages were made, but its working did not give satisfaction. It had three trunk cylinders with a stationary crank, and the general principle was similar to that of Mr. Rigg's engine.

In replying, Mr. Rigg said he was much obliged for Mr. Brown's criticism, coming as it did from one who had worked in the same field as himself. In the matter of oil his engine was not a wasteful one. If it were necessary to pump oil in, it could be done, but he had another method of supplying lubricant. He had no trouble with his valves whatever, because he had found that pressure tended to keep the faces apart. He had run his engine at a very high speed with 700lb. water pressure, and had no trouble with it.

The first paper read on the 28th ult. was by Captain C. C. Penrose FitzGerald, on "Leak-Stopping in Steel Ships." The question of how shot-holes in thin iron and steel are to be dealt with, when next our ships are called upon to receive as well as to fire shot and shell, is one, he said, that has not attracted the attention which its importance demands. In the naval manœuvres we entirely ignore the effect of an enemy's shot piercing one of our ships. It would, of course, be expensive to fire at our own ships, but it might throw some useful light upon disputed questions in naval architecture.

The author said that the following practical questions suggested themselves to the minds of many officers commanding war-ships with thin steel sides. "What will be the condition of the ship's side after ten minutes' action with an enemy, knowing, as we do, the armament and approximate rate of fire of most foreign ships?" Will, or will not, the ship's side be riddled with numerous small holes; to say nothing of the possibility of a large one or two?" "Will, or will not, the water come into these holes unless it is absolutely a flat calm, and the ship has no motion?" And, finally, "How to deal with these holes temporarily?"

Various devices have been suggested as substitutes for armour, in order to keep the sea from swamping steel ships when their sides are injured. Cellulose, woodite, india-rubber, and other substances have been experimented with; but there are objections to the use of all of them. The simple expedient of ordinary outside wood sheathing, extending from 5ft. below the water-line to 10ft. above it, would appear to offer the only method of attaching plugs to the side of the ship, and thus to

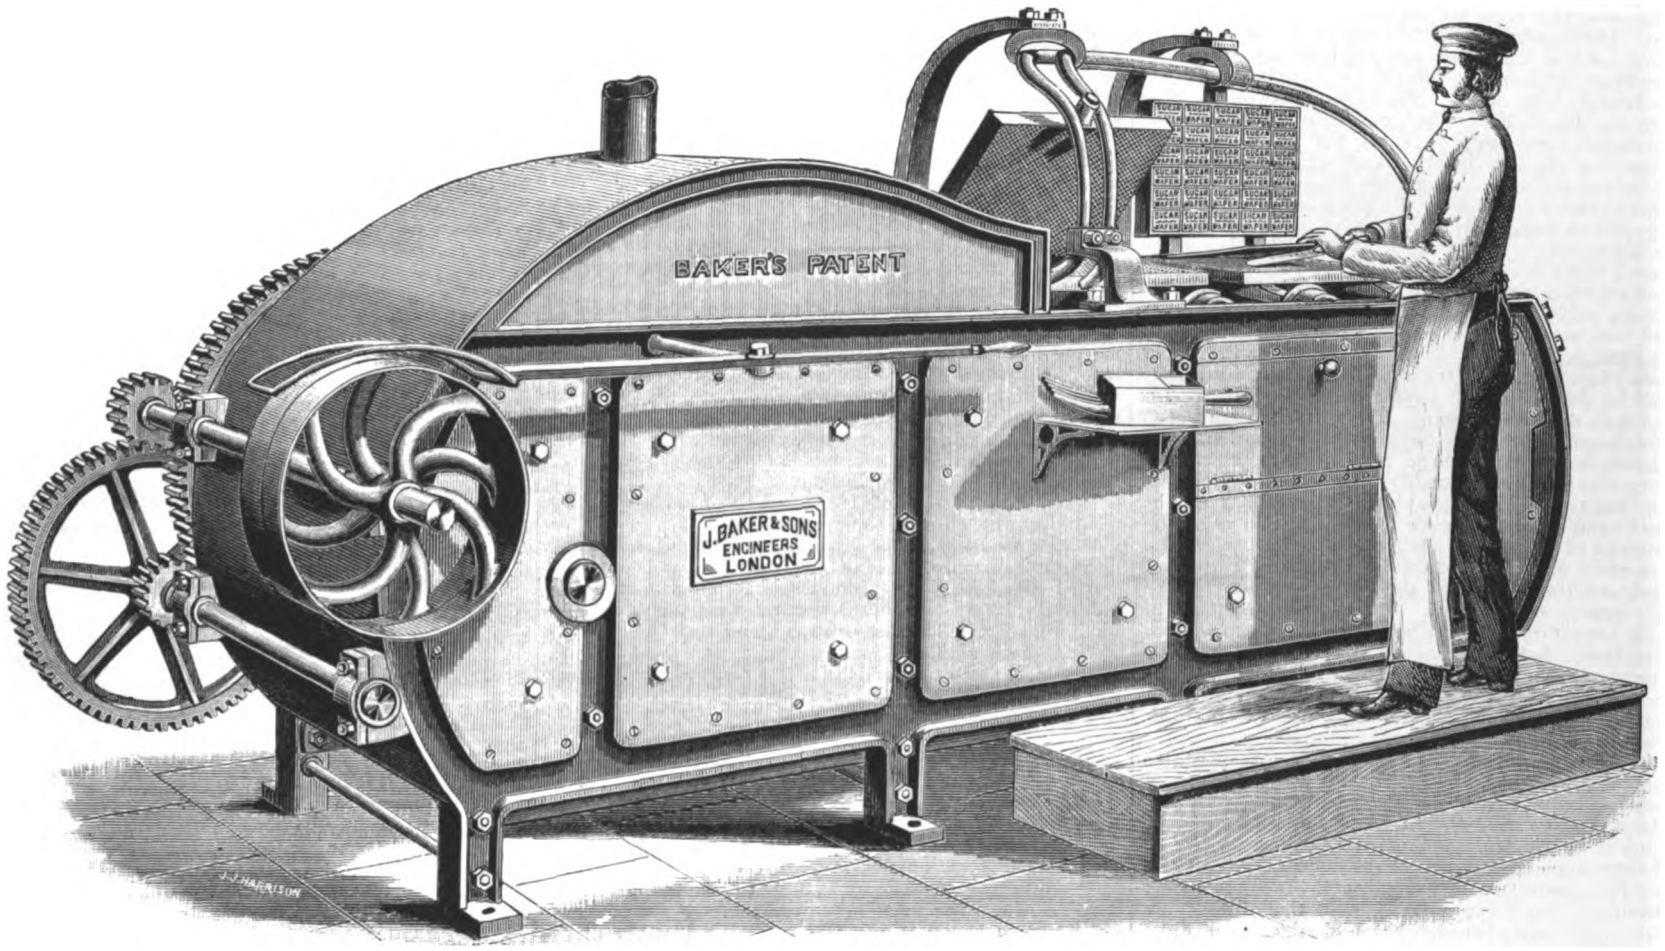

FIG. 3.—SUGAR WAFER MAKING AND BAKING MACHINE.

keep the ship afloat. Some of our ships are wood-sheathed already, but this, the author said, had been done with a totally different object—viz., that they may be coppered, and their bottoms preserved from rapid fouling, so as avoid constant docking.

The author proposed the following experiment: Take out into the Channel, at the back of the Isle of Wight, in moderate weather, two of our modern cruisers, with thin steel sides, and no external armour; let one of them be sheathed with 5in. elm plank, extending from 5ft. below the water-line to 10ft. above it; and let the other be unsheathed. Then fire at them—after removing the crews—that is, a few rounds from the 1in. Nordenfelt, the 3 and 6 pounders, and perhaps one or two rounds from 4in. and 5in guns. If it is thought desirable, the firing could all take place at one or two compartments; and, if necessary, some special arrangements might be made, with cork or otherwise, to avoid all risk of sinking. The author thought that all the holes in the sheathed ship would be dealt with and rendered practically water-tight long before the shipwrights in the unsheathed ship had made up their minds what they were going to do with their holes.

The author suggested a belt of wood sheathing about 15ft. wide—say 10 above and 5 below water—but it would, of course, be a matter for consideration whether, when so much as this has been done, it would not be better to sheath the bottom all over, and copper it.

There seems one objection which might be raised against the author's proposition, and that is that the splinters from the wood would be carried through the hole in the steel, and increase the havoc inside. However, if a tough, short-grained wood, like English elm, were used, very few splinters would find their way through the side.

Captain Long opened the discussion by saying that it was not necessary to fire at a ship in order to find out all that Captain FitzGerald had set forth. A great difficulty naval architects had to contend with was the progress of artillery, for the risks to a ship from under-water projectiles was very great. The number of torpedoes afloat had increased very much, and in a war they must expect to find great damage done by them, and no amount of sheathing would protect the boat against them. Some method of stopping up a hole from the outside while repairs were going on inside would claim attention.

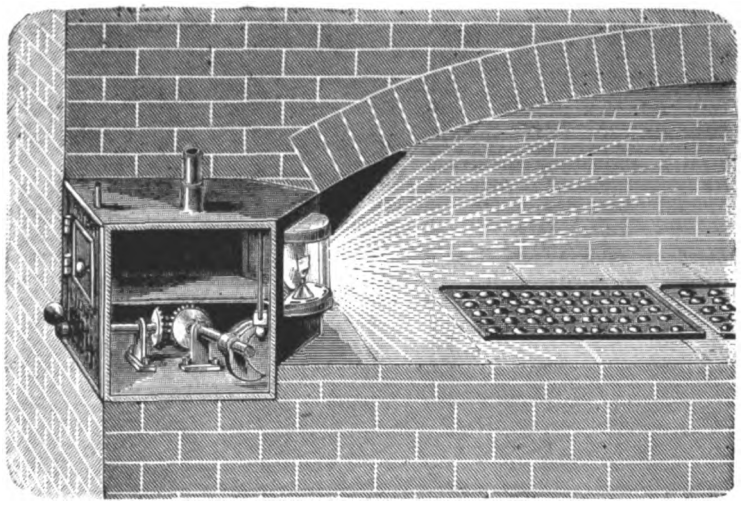

FIG. 4.—LAMP FOR SHOWING INTERIOR OF OVENS.

Mr. White said the utility or otherwise of wood sheathing could be demonstrated without firing at a ship. The progress of artillery and explosives had, however, rendered such experiments unnecessary. In a battle the high explosives and quick-firing guns would not make clean holes in the sides of a vessel, but great pieces of plate would be driven off. That being the case, to clothe the water-line region was useless. It was well known that the interposition of any increased resistance determined the explosion of the projectile at that very place. In our ships of the cruiser class the outer skin was made comparatively thin, and within the ship there were to be found appliances by which any great inflow of water could be prevented. The men would not often work with any water pressure against them, but on a floor which was above water, and with the help of appliances always ready for service. There was no hope of maintaining the water-tightness of a thin side, but large quantities of water might be kept out of the ship by the use of wood on the slopes of the protected deck in association with the cofferdams furnished to all our cruisers. Mr. White also said that the entry of water into the ship above the protected deck did not involve sinking; moreover, in all ships with protected decks the subdivision of space was very minute, and it was part of the design of the ships that a very moderate weight of coal should always remain in the angular space to limit the inflow of water.

Sir John Hay said it might be very desirable to prevent water coming into contact with the internal arrangements by taking the ship out of range to stop the shot-holes. Mr. White had reminded him there were collision mats to be employed to prevent the water coming in, but he doubted if officers had all the information which Mr. White possessed as to the most rapid means of stopping an external hole. The Navy ought to know what was the best way of doing this under fire, in order that the ship might be kept afloat.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 15th April, 1890.

Iron.—The market is languid, the recent further decline in English pig having had a depressing effect on business here. As a consequence prices have given way. Merchants are offering bars at 152s. a ton, but for orders of some importance even this does not represent the bottom of the market. Concessions of 2s., 3s., and 4s. a ton are easily obtained. Joists, which are not much inquired for, may be bought at 156s., and on this price concessions are made for moderately large orders. The demand has fallen off a little in the Haute-Marne; but, on the other hand, some improvement is announced from the Nord. The tendency of prices for pig iron in the Meurthe-et-Moselle is distinctly downward. Some time ago forge pig was offered to Belgian consumers at 56s. at the furnaces. This price not having proved sufficiently attractive, offers are now made at 52s. a ton, which is equivalent to 61s. 6d. delivered at the works in Charleroi. This fact is evidence of a feeble demand for home consumption.

Metals.—The efforts of speculators to give another upward turn to copper have proved successful, and we have again Chili bars at £54. But the quotation is rather nominal than real, for the movement has practically stopped for the moment all buying for consumption. Tin continues its downward course. The situation is now such that this metal may be expected to engage the attention of speculators before long. Lead remains firm. Spelter is dropping slowly but continuously.

The Treaties of Commerce.—The replies of the various Chambers of Commerce to the question asked by the Minister of Commerce relative to the renewal of the treaties which expire in 1892 have, for the most part, been received, and the opinion of the country is found to be strongly against such renewal. The Chambers of three of our most important seaports, however—Havre, Marseilles, and Bordeaux—have pronounced in favour of renewal. They point out that the incomparable prosperity of England is due to its ports being free to all the world, and that France can never hope to become a market for raw materials if her frontiers are closed to the importer.

The Chicory Industry.—The Agricultural Committee of Cambrai at an extraordinary sitting, at which upwards of two hundred agriculturists and several deputies were present, have passed a resolution strongly recommending the attention of the Government to a petition of the syndicate of chicory planters and dryers of the district of the Nord, praying for a protective duty on chicory. It appears from this document that the manufacturers of that district use annually 40,000 tons of chicory roots, of which quantity at least 25,000 tons are imported from Belgium. The petitioners say that if this import trade were checked by protective duties, 5,000 hectares of land in the North of France would be immediately planted. The duty asked for is 16s a ton on green roots, and 64s. a ton on dried roots.

The International Labour Demonstration.—Those who are organising the demonstration of the 1st prox. have prepared a petition, which the delegation of working men are to transmit to the Government. It is as follows:—"International demonstration of the 1st of May, in favour of a day of eight hours and a legislation protecting labour, leading, with the eight hours day as an essential basis, to a guarantee of a minimum of pay, to the limitation of the labour of children and women, and to rest for one day in the week. Petition.—The undersigned citizens claim, as the most urgent of all reforms, the limitation by law of the day's work to a maximum of eight hours, because the day of eight hours is work and bread for numbers of labourers who crowd with empty stomachs at the doors of workshops; because the eight hours day will put an end to the periodical strikes which multiply with machinery; because the eight hours day will cause an inevitable rise in wages by suppressing the homicidal competition between the unemployed and those who have work; because the eight hours day is, with eight hours' sleep and eight hours' leisure, life, liberty, and action for the working classes; because the eight hours day will benefit petty trade itself by increasing the power of consumption and purchase by its working-class customers." It is said that 200,000 working men will leave their places of business on the 1st of May and take part in the demonstration in the streets of Paris.

BERLIN, 14th April, 1890.

Iron.—The breaking up of the Upper Silesian pig iron syndicate is another important sign of the times. As English iron is offered for delivery at the price of German produce, the latter is now being offered at a reduction of 5s. and 6s. a ton. The tendency of prices all round is towards a lower level. The downward movement will, however, be slow, because manufacturers have sufficient orders in hand to keep them going for several months to come. The market continues active for finished iron and steel; but the state of the pig iron trade is likely to make buyers of finished produce hesitate. Joists and boiler plates are in very brisk demand. Here in Berlin business is a little slacker, and prices are somewhat weak. Founders continue to receive orders in abundance. Great activity prevails in the machine shops. The foreign trade in manufactured goods is full of life and vigour. The exports of machinery, other than locomotives, boilers, and sewing machines, in the first two months of the year amounted to 10,724 tons, against 9,962 tons in the corresponding period of 1889.

Metals.—There is but little life in the metal markets. Copper maintains its price, though the demand is slack. The zinc market is flat. Manufacturers' prices for spelter remain on the whole unchanged, but merchants are offering their stocks at lower rates. At Breslau some transactions have taken place below £22. The restriction of the consumption caused by high prices is now making itself felt on the markets, which are likely to give way seriously before long. Lead, which is in fairly strong demand, maintains its price firmly.

Flax and Yarns.—All reports agree in describing the situation of the market for linen yarns as good, and the prospect as encouraging. There is a strong and steady current of business that seems likely to continue. For the moment the supply of linens is scarcely equal to the demand. Tows are offered in large quantity; but buyers are numerous and deal freely. Prices are very firm. The imports of yarns in the first two months of the year amounted to 39,886 cwt., against 37,360 cwt. in the corresponding period of 1889.

The Ultramarine Industry. An attempt is being made to combine in one association or syndicate the ultramarine manufacturers of Germany. The association will be of the nature of a share company rather than a convention of manufacturers. Judging from the progress already made, the attempt will be successful. The export trade in ultramarine is steadily growing. The quantity exported in the first two months of the current year amounted to 15,252 cwt., against 12,868 cwt. in the corresponding portion of 1889. Of the former quantity 6,562 cwt. were shipped to Great Britain.

Bavarian Beer.—The financial situation of the great breweries and malt-houses of Bavaria is said to be critical. During the last three years these formerly flourishing industries have been losing ground, particularly in the foreign markets. The last straw, which seems to be breaking the back of this Bavarian camel, was the influenza epidemic, the effect of which on the consumption of beer was very marked.

VIENNA, 14th April, 1890.

The Coal Market.—The brisk demand for coal continues. Prices are very firm, and people are sure that a further increase is certain. The labour question in Westphalia causes an animated export, and Bohemian and Silesian works are very busy, notwithstanding the warm weather which has existed for a fortnight. The demand for waggons which is continually felt in the Bohemian territories has persuaded the Ministry of Commerce to apportion 300 coal-cars of the State Railways to the Dux-Bodenbach line and 615 to the Prague-Dux Railway. A hundred waggons of the 600 ordered by the Dux-Bodenbach Railway have already been delivered, and the Aussig-Teplitz line has enlarged its rolling stock by 14 per cent., so it is to be hoped that the traffic will in future be better arranged. During the first quarter of the present year the Dux-Bodenbach Railway forwarded 495,675 tons, and the Prague-Dux line 311,582 tons of brown coals. The Bohemian collieries are now taking stock, and the reports are all expected to be good. The Duxer Kohlenverein produced 550,587 tons last year. The great increase of wages has caused the profit to become lower; it amounted to 68,000 florins, and the dividend was 4 per cent. The Bruxer Kohlenbergbau-Gesellschaft is increasing its capital from 2½ to 3½ million florins.

The Iron Market.—The character of the Austrian iron market does not change. In all branches there is the same animation, and the transactions are very important. In pig iron the production cannot cope with the demand. Agricultural machine manufactories have received important orders, and have a good prospect. Locomotive constructors have a great deal to do. The Wiener-Neustadter Locomotiv Fabrik is recovering its old position, for it is sharing in an order for 200 locomotives for a German railway, and is to build 40 locomotives for a home railroad company. In Hungary the tendency of the market is essentially different from that in Austria. Foreign influences are not visible, and the market has to be self-dependent.

Electrical Engineering.—A new central electric station is to be erected at Karlsbad by Messrs. Ganz & Co., of Budapest. When completed it will be the largest station in Austria-Hungary out of Vienna.

Beer.—It is proposed to establish two new large breweries at Pilsen. The capital for one will be found by the Vienna Bank, and the other will be under the wing of a London firm.

Trials with the Maxim Gun.—The experiments with the Maxim mitrailleuse were successfully concluded at the Vienna Arsenal last week, after 34,000 rounds had been fired from one gun within four days. The good quality of the steel and of the manufacture was thus amply demonstrated.

BRUSSELS, 15th April, 1890.

The Iron Market.—The syndicate of ironmasters again met last week to consider the state of the market. The continued scarcity of orders is very serious, but the dearness of the raw materials makes it utterly impossible for them to reduce their prices for manufactured goods. There was, therefore, only one course open to the syndicate, and that was to determine to decrease the production. An understanding has been come to among the manufacturers of sheets and bars in the various districts that they are only to work five days a week until the situation is changed. Bars are still quoted at 18fr., and No. 2 sheets at 22fr. The adjudication of the contract for steel rails referred to last week has settled the price of that commodity at 177·50fr.

The Coal Market.—The position of the coal market does not change, and the prices are firm all round. The stocks have everywhere been reduced to almost nothing. *Demi-grasses* for household use are sold in large quantities at 20–21fr.; nuts of best quality are quoted at 27–28fr., and of second quality at 25–27fr.; nuts for rolling mills at 18–19fr.; *fines demi-grasses* at 16–18fr.; close burning coal at 15fr.; and small coking coal at 22fr. In some of the coal districts the owners have been able to sell nuts for rolling mills at 20fr.

The Glass Trade.—The condition of the window-glass market remains unchanged. The efforts of buyers to obtain a reduction of the prices have so far been unsuccessful, and it is likely that their efforts will be resisted to the death, on account of the high prices of fuel and raw materials.

Telephone-Telegrams.—During the month of March 64,062 telegrams were sent from the central telegraph stations of Belgium by order of the various subscribers to the telephone systems. The greatest number of these telephonic messages were received in Antwerp—viz., 20,922, and the next town was Brussels with 10,788. This recent improvement is evidently much appreciated.

DÜSSELDORF, 15th April, 1890.

Iron.—There is but little doing in pig iron, buyers manifesting unwillingness to operate at present prices. This reluctance has been increased by the announcement of a heavy output of the blast furnaces in the month of March. The total production of the furnaces included in the Rhenish-Westphalian pig iron syndicate amounted in that month to 127,231 tons, against 111,656 tons and 117,778 tons in February and January respectively. From Luxembourg it is announced that three new furnaces are to be put in blast in the course of the current month. Further, Belgian trade is very slack, and French prices are giving way, so that foreign competition is likely to become more keen. Lower prices are therefore probable as the year advances. The following are the current quotations, but merchants readily make slight concessions on orders of some importance:—Ordinary spiegel, 103s.; best Rhenish-Westphalian forge pig, 90s.; Siegen forge, 89s.; foundry No. 1, 96s.; Thomas pig, 79s. to 80s. a ton. The market is moderately active for all classes of finished iron and steel, except wire, for which the demand is very slack. Prices remain unchanged.

Coal.—For the coal trade the situation continues to improve. Day by day, as the split in the Socialist camp widens, the chances of another conflict between the colliery owners and their men grow less. The contented are now in a majority, and they seem resolved to make their counsels prevail. This circumstance sufficiently accounts for the more cheerful tone of the markets. That the situation is a strong one is shown by the fact, reported this week, that most of the coal producers are sold forward to the end of next winter. In some cases the contracts extend to July, 1891. As these contracts have been made at prices recently current, the situation and prospects of the coal-mining industry are exceptionally good. The railways, having largely added to their rolling stock of late, are now able to cope with the traffic, and the Belgian coal trucks hired a year ago are now being returned. Coke has given way a little in price, but the market is steady for coal of all classes. The following are the quotations on the Düsseldorf Exchange:—Gas coal, 16s. to 18s.; free burning coal, large, 15s. 6d. to 16s. 6d.; washed nuts, 14s. to 16s.; coking coal, 14s. to 16s.; dry-burning coal, large, 16s. to 19s.; nuts, 17s. to 20s.; small, 7s. to 8s.; blast-furnace coke, 25s. to 27s.; foundry coke, 27s. 6d. to 29s.; and briquettes, 16s. to 18s. a ton. Anthracite nuts have risen 3s. a ton within the last week.

Westphalian Coal at Hamburg.—The high prices of coal in Germany are beginning to tell upon the Westphalian trade with Hamburg and its neighbourhood, in spite of the advantages afforded by the new and commodious wharfs. The consignments of Westphalian produce to that locality in March amounted to 69,730 tons, against 76,190 tons in the same month of last year. During the last week both Westphalian and English coal has been offered at slightly lower prices.

Electric Lighting.—The Commission appointed by the Düsseldorf Municipal Authorities to examine and report on certain schemes for lighting by electricity say, in a report just presented, that during the time in which they have been occupied in this inquiry—less than twelve months—new inventions and improved forms of construction have come upon them with such rapidity that the aspect of the case has been constantly changing, and they find themselves unable to advise immediate action. While progress continues at the present rate there is nothing to lose by waiting.

Digitized by Google

LILLE, 15th April, 1890.

Iron.—During the last week the iron market has manifested greater activity, a circumstance which has raised hopes of better times. To the unbiassed observer, however, the larger volume of business will appear merely as the effect of the interruption in the previous week by the Easter holidays. But we are entering upon a season when, in the ordinary course of things, trade becomes more brisk, so that we may reasonably expect some improvement in the next few weeks. Prices are firmer, but it is hard to see how, with falling markets abroad, the present rates are to be long maintained. The weakness of the situation in Paris has an enfeebling influence on the market here. The price of coal seems likely to give way a little.

Textile Manufactures.—There is some revival of trade in linen goods. Orders are coming to hand much more freely, and in sufficient abundance to absorb the whole of the production. There is, therefore, a better tone in the market, the prospect being now regarded as distinctly encouraging. Similarly an improvement is taking place in the woollen goods trade of Roubaix. There is, indeed, no revival of business to chronicle; such is not to be expected at this season. But signs of activity at a later period are multiplying, and the manufacturers are beginning to view the approaching busy season hopefully. Some labour disturbances have occurred to complicate the situation; but no serious troubles are expected. There is nothing new to report of the Calais tulle trade, which is very dull, with but little prospect of speedy improvement.

Flax and Yarns.—The flax market continues active. Home-grown is in brisk demand, all lots offered being promptly bought up. Prices are very firm. There is a little more doing in Russian produce, chiefly for future delivery. Tows are but little inquired for, and prices are weak. Quite a brisk market exists for yarns. Jute yarns continue in strong demand, especially the fine and middle numbers, the tendency of prices being in favour of buyers. There are practically no stocks in hand.

State of Industry.—The Lille Chamber of Commerce, in reply to a set of questions addressed to it by the Superior Council of Commerce and Industry, describes the general state of industry in this locality as "not prosperous." A few exceptions are mentioned, of which the jute industry is one. But the staple industries leave much to be desired. The principal cause is said to be insufficient production, and a revision of the duty tariffs for imported goods is asked for.

AMSTERDAM, 14th April, 1890.

Artisans' Congress in Amsterdam.—The National Dutch Artisans' League has been assembled for two days at Amsterdam. Various topics of interest to the labouring classes were discussed at some length. One of the most important debates was on the question of forming a fund for old age, and for the widows and orphans of artisans. It was resolved to petition the Government to introduce special legislation as to the removal of unsanitary dwellings, and the substitution of hygienic workmen's houses out of the public purse. The establishment of strike funds in various localities was gone into, but this question was postponed. The League has now 3,000 members.

Textile Industries.—The Chamber of Commerce of Tilburg, in Brabant, the centre of our textile industries, has issued a favourable report of last year's work in that district. There was a more ready sale for Dutch textile products abroad, and at more remunerative prices. The consequence was that most manufacturers could work full time. The Chamber states that hand labour is gradually being superseded by mechanical labour. On the other hand, the Chamber of Commerce at Schiedam has issued a rather gloomy account of the "Hollands" industry in that centre.

The "Zone" Railway System in Holland.—The managers of the leading railways in Holland are now discussing the feasibility of introducing the "zone" system on their lines. They have despatched delegates to study the question in Hungary, where the system was first introduced. It is believed that the Austrian Government will be authorised by the Reichstag to follow suit, in which case the "zone" system is almost certain to spread to Germany. The Dutch railway managers want to be prepared for such an eventuality, since the experiment has been highly successful. In the "zone" system the country is divided into "zones" or districts: hence the name. Its feature is uniformity of fares within one district, any distance, and also uniformity of fares from places in one district to places in another district. The method is confined to passenger tariffs, but it is now proposed to apply it to goods rates as well.

Dutch Steamboat Companies. The Netherland-American Steamboat Company, with lines from Rotterdam to New York and South America, has been very successful in 1889, and is enabled to distribute amongst its shareholders a dividend of 17 per cent. The Royal West Indian Steamboat Company has declared a dividend of 6¼ per cent. over the past year. The new shares, amounting to 400,000 guilders, were over-subscribed upon their issue. A Dutch syndicate has offered to the Roumanian Government to start a line of steamers on the Danube under the Roumanian flag.

Shipbuilding.—Messrs. Fop Smit, at Kinderdyk, have just launched a new saloon steamer for passenger traffic on the Rhine between Cologne and Mayence.—Messrs. Bonn & Mees, shipbuilders, of Katendrecht, are engaged upon the new steamship "Leerdam," the property of the Netherland-American Steamboat Company. It will measure 360ft. in length.—The shipbuilding yard and machine factory of the Maas Company, Rotterdam, has made a profit of 40,923 guilders in 1889. The directors propose to write off 25,000 guilders for depreciation, &c., and devote 15,000 guilders to paying a dividend of 5 per cent. on the shares, such dividend not to be distributed, however, until the claim of the company against the fire insurance companies shall have been settled, for the company has had the misfortune of losing its factory by fire quite recently. These proposals have been approved by the shareholders, who have also authorised the directors to re-erect the buildings destroyed as soon as practicable.

The Amsterdam Ship Canal.—The Royal Institute of Civil Engineers has appointed a special committee to study the question of a ship canal of even larger dimensions between Amsterdam and the ocean, than the one at present existing, such canal to be available for vessels of every draught and at all times and tides.

New Company.—The Dutch Oyster Fisheries Company, with a large capital, will shortly issue its prospectus. Its object is to buy up and amalgamate various private oyster cultures, with a view of developing them in a more systematic manner.

COPENHAGEN, 12th April, 1890.

A New Swedish Ironclad.—Although the Swedish Parliament is by no means liberal in its grants to the army and navy, there seems every likelihood of the necessary money being voted for a third ironclad. She would be of the same type as the "Svea" and the "Gota," with some minor alterations so as to ensure a greater speed.

The Fishing Industries in Denmark.—These industries do not seem to be particularly flourishing, judging from the official statistics for the financial year 1888-1889. The number of men engaged in fishing was 7,369, which shows a decline as compared with the previous year. The value of the fishing during the year, inside the Scaw, amounted to 2,964,970kr., which is about 500,000kr. less than the previous year. This decrease in value is owing to a smaller yield, and not to lower prices.

Proposed Zone or Section Railway Fares in Sweden.—The Swedish Parliament has recently been considering a privately introduced Bill proposing a system for railway rates such as has been adopted in Hungary. There may be difficulties attached to the introduction of this method, but the extra expenses entailed would hardly grow any faster than the income.

Naphtha Transport in Russia.—The almost unprecedented development, during the last few years, of the naphtha production in Russia, and the increased tendency to export, have taxed the existing means of transport very severely. Under these circumstances the Transcaucasian Railway from Baku to Batoum and Poti, *viâ* Tiflis, is unable to satisfy the requirements of the exporters. The exports last year of naphtha from Baku alone amounted to an aggregate of 660,000 tons, which quantity would have been still further increased had the above railway been more efficient. Other means of transport have been under consideration, the most ingenious plan being the laying of a gigantic tube or pipe from the Caspian to the Black Sea. About three years ago a concession was given for this unique undertaking, but the holder of the concession was unable to carry out its financial conditions. In the meantime one or two enterprising English capitalists have been negotiating with the Russian Government about the realisation of the scheme, but, although the prospects were favourable at one time, nothing came of it in the end. It is understood that the Russian Government itself contemplates the carrying out of the plan.

MADRID, 14th April, 1890.

Railway from Calatayud to Feruel.—The surveys of this line seem to have deen done so carelessly that new ones have had to be carried out before the commencement of the works. This is not only very costly, but it also causes great delay to the concessionnaires, who have not a very ample time to open the lines of their concessions.

Lighting by Primary Batteries.—A public exhibition has been made of a system of electric lighting with a primary battery, the invention of Major Cabanyes, of the Artillery Corps. The patents not being completed, little information of a technical character was given about the nature of the battery. Of course, some very extensive details were given as to the commercial value of the system, and it is quite possible that it could compete with the dynamo central stations which are now being erected in Madrid, on account of the absurdly high prices demanded by the latter.

The Protection of Property.—The Congress of the International Union for the Protection of Industrial Property has just commenced at Madrid. One of the points that is being discussed is of great interest for England and Spain—viz., the right of seizing imported goods which are marked as the production of a certain place when it is not actually the case. Sheffield articles made in Germany and marked Sheffield, and imitations of Spanish wines imported marked Serez, Malaga, &c., will run a geat risk of being seized, and it is to be expected that the Union will put an end to that practice. Another important question to be dealt with is, whether articles can be imported into a country where there is a patent for its manufacture. Most nations are willing to adhere to this resolution, but England is most decidedly against it, and there is not the least chance that her representatives will yield.

Iron Mines in Biscay.—So far most of the iron mines in Biscay have been of comparatively small extent. Lately, however, some concessions have been demanded at the district of Ceanuri, amongst which there is one of 470 hectares and another of 289 hectares.

NEW YORK, 5th April, 1890.

The Coal Trade.—There has been no change for the better in the anthracite trade. Low prices are being quoted for store and chestnut sizes; coal, which sold at $4 to $4·15 per ton under the old circular rates, can now be bought at $3·25. Larger sizes, which are in greater demand, are bringing rates more nearly equal to the old ones. It is probable that the forthcoming re-opening of canal navigation will increase the demand. Stocks of coal in New England are getting low, and a better demand is expected from that quarter soon. At a meeting of the sales agents of the six great coal companies it was decided to continue the policy of restriction, and the production for the month of April was fixed at $2,000,000 tons. No action was taken with regard to prices.

A Combination of Papermakers.—An attempt is being made to unite several of the larger New York paper companies under one control. It is probable that the Remington Co., the Hudson River Pulp and Paper Co. of Palmer Falls, the Glennsfalls Paper Manufacturing Co., and the Rochester Paper Co. will unite their interests, and the new company will have a capital of $5,000,000.

Iron and Steel.—There is considerably more inquiry, and there are evidences of an inclination among consumers to replenish their stock as soon as they are satisfied that prices are as low as they are ever likely to be. Stocks have not accumulated to any great extent, and a few more heavy orders would change the state of the market entirely. Prices for pig iron are about the same. Any quantity of common brands can be obtained at current rates or lower, but there is not a great quantity of choice iron to be had. In manufactured iron the demand has been more active, but most of the business has been in small lots. Many of the mills are getting near the end of their old orders, and prices are not likely to become much better until some new work comes to hand. There has been little doing in steel rails. Prices are held steadily at $34 to $34·50 per ton at mill. There is every probability of an increase in the demand in the near future.

Electrical Accumulator Company.—The trustees for the holders of the first mortgage bonds of the Electrical Company have begun suit in the Supreme Court to foreclose a mortgage for $1,000,000 on the company's property in New York and New Jersey. The company issued stock for $957,400, and executed a mortgage of $1,000,000. A default was made in the payment of interest in June and December last. The trustees also want a receiver appointed, and an injunction to restrain the company from disposing of its property.

PHILADELPHIA, 4th April, 1890.

New United States Battle Ships.—The Naval Appropriation Bill has been completed in committee. The total appropriation is for $22,151,523, which is about 3½ million dollars less than the Navy Department estimates. Provision is made for four new vessels far beyond anything yet undertaken in America. Three of the vessels are to be sea-going coast defence line-of-battle ships of about 8,500 tons, designed to carry the heaviest armour and correspondingly heavy ordnance. They are to carry enough coal to allow them to steam 5,000 miles, and to have as high a speed as is compatible with the other qualities required. They are to cost not over $4,000,000 each exclusive of armament. The other vessel is to be an armoured cruiser of about 7,300 tons displacement, and it is to cost not over $2,750,000. It is to have a minimum speed of 20 knots. One is to be built on the Pacific Coast and one on the Gulf of Mexico. The Secretary of the Navy can build the vessels in the yards if the work cannot be done at reasonable cost by private contract.

The Largest Wooden Vessel Afloat.—It is rather interesting to observe the survivors of any race, especially when there is something exceptional in their form and appearance. There recently arrived in the port of Philadelphia the wooden vessel "Kappahannock," which is said to be the largest wooden vessel afloat. She was built at Bath, Maine, and cost $125,000. Her dimensions are 287ft. long, 48¾ft. beam, and her tonnage 3,053 net. In the construction of the ship 700 tons of Virginia oak and 1,200,000ft. of Virginia pine timber were used. The frame is of oak, well seasoned when put up, and the first quality of Georgia pine was used in the ceiling, deck frames, and planking. The main keelson is 3ft. 2in. in depth; bilge keelsons, 14in. flush; lower deck beams, 15in. by 15in.; 'tween deck beams, 12in. by 14in.; and the spar deck beams at the main hatchway are 18in. by 18in. The "Kappahannock" is the heaviest sparred ship that ever carried the stars and stripes. Her mainmast is 89ft. long and 38½in. in diameter; the maintopmast, 58ft.; maintop-gallant mast, 71ft.; mainyard, 95ft.; foreyard, 95ft.; and, altogether, she has a spread of canvas of 15,000 yards. The lower masts are of Georgia pine, and the other spars of Oregon pine, but, curiously enough, the bowsprit is of steel.

BISCUIT MAKING MACHINERY.

Exhibited by Messrs Joseph Baker & Sons, at the late Paris Exhibition.

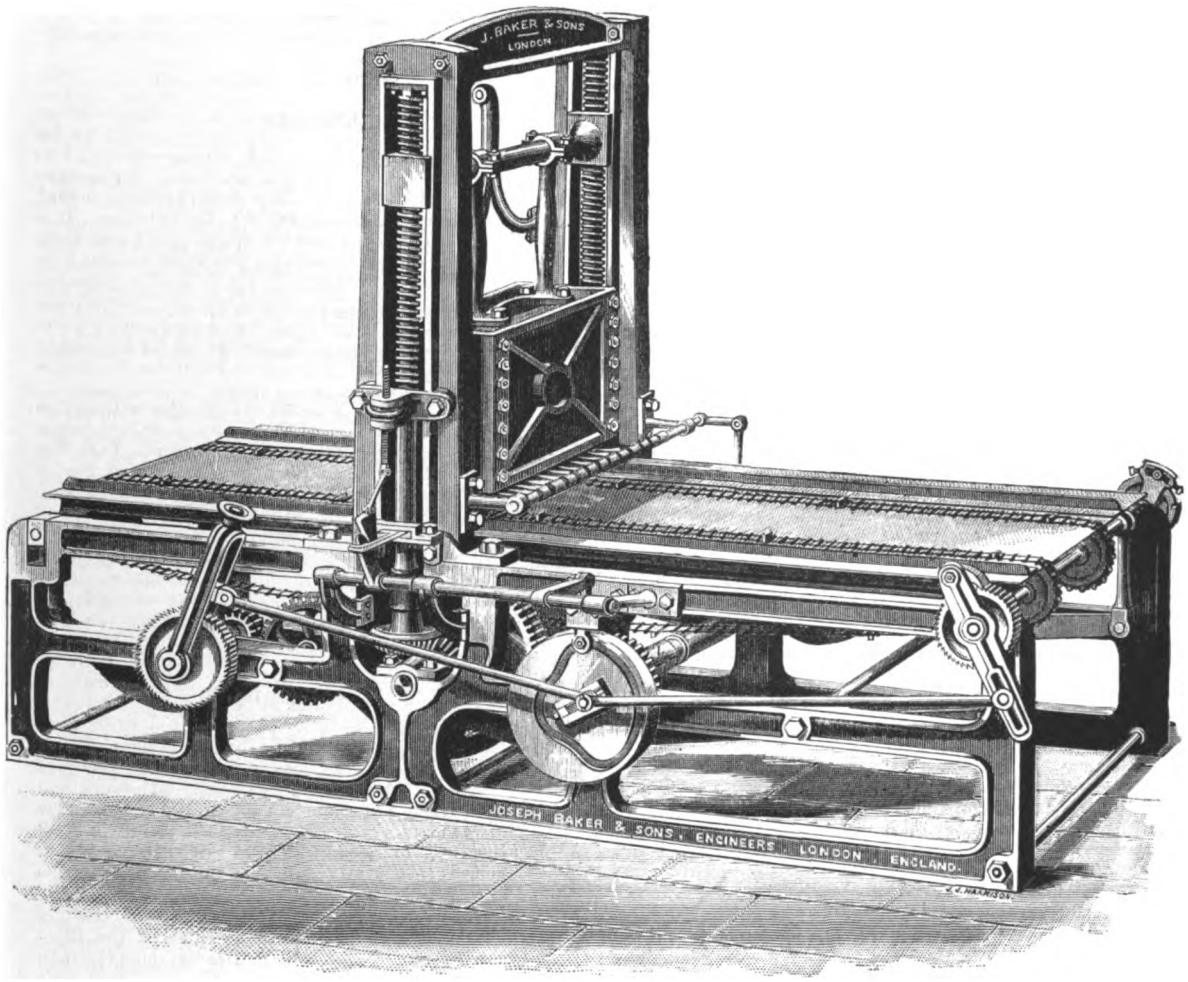

Fig. 5.—Machine for Making Drop Biscuits.

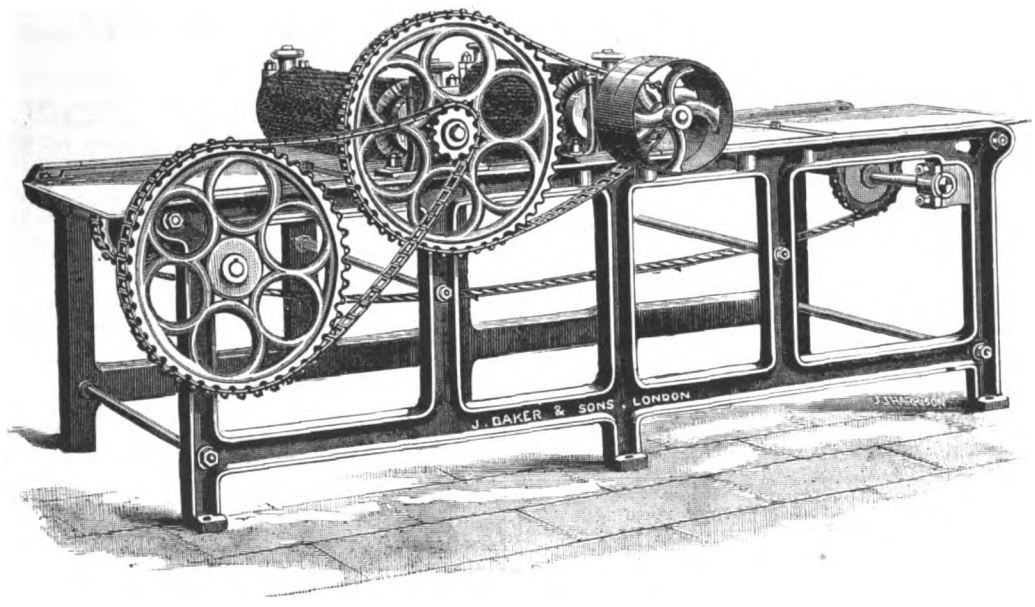

Fig. 6.—Machine for Cleaning and Greasing Pans.

MESSRS. JOSEPH BAKER & SONS' BISCUIT MAKING MACHINERY.

Messrs. Joseph Baker & Sons, 58, City Road, London, had the largest and most complete collection of bread and biscuit making machinery at the late Paris Exhibition. The exhibit contained many entirely new machines, and their machines of older types had some conspicuous improvements embodied in their design. As it will be of interest to our readers to see the modern applications of machinery to so old an industry as biscuit making, we purpose to give as full as possible an account of several machines.

Fig. 1, page 361, shows their improved vertical mixing machine for rich, soft, and semi-soft biscuit doughs. This machine will knead a sack of flour in eight to ten minutes. The tub containing the flour is firmly fixed on the bed-plate of the machine, and the mixers are lowered into it. They are balanced by means of a weight which passes over a pulley at the top, and they can be raised or lowered by means of friction gear at the back. This arrangement avoids the necessity of raising the tubs to the mixers, and is a great improvement on the old form of machines, as it avoids the risk and danger of raising and lowering heavily loaded tubs. The tubs are fitted with wheels, so that one can be substituted for another as soon as the mixing is done. The mixers are driven by strong bevel gearing, and they can be raised or lowered by friction gear, which moves them automatically through the distance required without throwing the rest of the machine out of gear. Messrs. Baker also have a horizontal cylindrical mixing machine for hard biscuit doughs, in which the kneading is done by horizontal mixers mounted on the same shaft but driven at different speeds. The flour is supplied by three hoppers, which distribute it over the cylinder. The mass when kneaded is emptied on the receiving table by tilting the cylinder forward with the help of a worm and worm wheel. The machine is kept closed during the kneading, so as to exclude all dirt, instead of being left open as formerly.

Fig. 2, page 364, shows the combined hard and soft dough biscuit gauging, cutting, and framing machine. This machine is fitted with a scrap-separating and self-framing apparatus, an improved chain gear for carrying pans and wires, a new "skip motion," and a revolving brush or fan. The gauge rollers give the required thickness to the dough, which enters at the left-hand side of the machine. After passing through these rollers it is carried forward by means of an endless band, to and under a revolving brush, or, if required, under a revolving fan. The crimp roller takes the place of the revolving brush in the making of certain kinds of biscuits, and this crimps the biscuits on the top before they pass onwards to the cutters. After the biscuits are cut from the dough the "scrap" is divided from the biscuits by a separating web and roller, while the biscuits are carried forward and automatically deposited upon the pans or wires. During this operation the new "skip motion" ensures that every biscuit is deposited regularly upon the pans, and when one pan or wire is filled it is hitched forward so that the succeeding biscuits are placed on the next pan or wire without any of the biscuits being deposited on the edges of the two pans or between them, as was the case before the "skip motion" was invented. The gauge rolls have a continuous motion given to them by means of one of a number of change wheels. A new spring adjustment fitted under the bearing of the top roller takes up the wear. These improvements prevent all creasing of the dough, and ensure perfect and regular working, thus giving a great advantage over the irregular motion of the ratchet wheels formerly used. The driving pulley has three speeds for the various sizes of biscuits.

Fig. 3, page 365, shows Messrs. Baker's sugar wafer making machine for automatically making and baking sugar wafer biscuits. The plates, when freshly charged with the required quantity of batter, are closed automatically and passed into the baking compartment. The time occupied in their passage is sufficient to bake them, and on passing out the plates open automatically for the removal of the baked sheet of wafer, and are ready to be again charged. The plates are all linked together by connecting shafts, and are carried by wheels, which run on endless tracks. The time required for the complete circuit of the plates is four or five minutes. The machine is made either with a slowly continuous motion, or with a stop motion, that brings the plates to a stop in front of the operator, in order that he may remove the sheet of baked wafer and recharge the plate with batter. The slowly continuous motion, however, is preferred. The oven is heated by gas, and the two sides of the plates are heated equally. The heating may be regulated to the greatest nicety by simply turning the taps and regulating the current of air which is forced through the pipes by the firm's pressure blower. The entire machine is enclosed with sheet iron plates and packed with asbestos, so as to prevent any loss of heat. The wafer plates are all faced with gun-metal and are electro-plated. Very little power is required to drive the machine, ⅓ h.p. being more than sufficient.

Fig. 4, page 365, shows a sectional view of Baker's patent oven gas light, which is so constructed as to give, when required, a brilliant light all over the oven at once. By touching a small ball handle, the fire door inside is instantaneously opened, and in its place the light appears, showing the baker every part of the oven, through a small window in the oven door. No door has to be opened, either for operating the light, or for seeing how the baking is going on. The losses of heat and steam caused by the opening of the oven door and damper are thus entirely avoided, and the heat and steam are kept in the ovens. The light is ventilated so as to be unaffected by the heat or steam.

Fig. 5 illustrates their new drop biscuit machine for making all kinds of drop biscuits, such as macaroons, ratafias, &c., which are usually made by hand. The dough is placed in a rectangular iron box, which is placed between uprights. The piston which presses down the dough is first tilted upwards so as to allow the dough to be placed in the box. It is then placed in position, and gradually descends to the bottom of the box, forcing out the dough through dies of various shapes which are screwed to the bottom of the box. A sliding knife runs across the face of these dies, and checks the flow of the dough, and allows it to fall at regular intervals upon the pans beneath. These pans,

Digitized by Google

by an automatic arrangement, rise to receive the dough, and then, on falling, move forward so as to leave room for the biscuits at the next rise. This pan-shifting gear can be so arranged as to receive biscuits at an instantaneous drop or to draw them out into such shapes as the finger biscuit. When the dough has been discharged the press returns rapidly and automatically to its original position, so that the box can be refilled. The baking pans are placed on endless chains, and are carried regularly forward to the drop pipes, which are placed below the dough box. When in position for receiving the drops, a lifting motion is given to the table below the pan, which brings it up in position to receive the drops from the ends of the pipes. Perfect evenness and uniformity of shape and size are ensured by means of the automatic cut-off slide which works transversely above the tops of the pipes, and which allows an exactly equal quantity to enter each pipe and to be measured and cut off at the same instant. The plunger is worked by two powerful screws fixed in the side frames of the machine, and the gearing is so arranged that when the plunger reaches the bottom of the box it runs up automatically by a quick return motion, and is moved to one side out of the way, so as to admit of the dough box being refilled. Hence the work can go on continuously, as rapidly as the pans can be placed on and removed from the machine. No further attention is needed when the machine has been started than to put on the empty baking pans and remove the full ones, and to refill the empty dough box. The new "skip motion" hitches the filled pan quickly forward and replaces it with an empty pan, so that no biscuits fall between or on the edges of the two pans. The machine can turn out at a maximum 2 tons of biscuits a day.

Fig. 6 shows Messrs. Baker's pan cleaning and greasing machine, which diminishes the labour and expense of cleaning biscuit plates or pans by hand. The machine consists of an iron framework having an endless chain running along the top and returning underneath. This chain has projecting links arranged at distances apart equal to the length of the pans. The pans to be cleaned are placed on the top of the chain between guides arranged for the purpose, and are carried forward by means of the projections in the chain under two brushes, which revolve in the opposite direction. The first brush is made of stiff bristles and revolves at a high speed, but the second is made of softer bristles and revolves at one-third of the speed of the first brush. The effect of this is that the first brush cleans off all particles adhering to the pan, and deposits the grease, while the second makes the surface of the grease equal and light all over.

Figs. 7 and 8, page 372, represent the new combined rout biscuit press, cutting and panning machine. Fig. 7 shows the machine as arranged and fitted with the special attachments, dies, travelling web, and cutting and panning gear for all kinds of ordinary rout biscuits, as "oaten," "cable," or "twist;" and Fig. 8 shows the machine, with special front, dies, cutting knife, and panning attachments for "rose," "café," and "ring" biscuits. This machine is used for doughs slightly tougher than those used in the drop machine. When the machine, as shown in Fig. 7, is making cable and twist biscuits, the dough is placed in the square iron box receiver at the left. A plunger forces the dough slowly out through the circular dies shown at the right-hand end of the dough box. A worm gives the dies a circular motion, which sends the dough out in long ropes. These ropes are carried forward by the endless web, and they pass under the cutting block at the right-hand end of the machine. This cutting block cuts them either at right angles or diagonally into the lengths required, and they are then deposited upon the pans, which run along upon an endless chain underneath. In Fig. 8, where rose and café biscuits are to be produced, the dough is forced vertically upwards through the dies. It is cleared from the dies by a special sliding knife, and is then deposited directly upon the pans which pass underneath. The knife itself is cleared of the biscuits by an arrangement of automatic elastic brass fingers, which meet the knife at the moment it touches the pan. This machine produces every variety of press goods more economically than has hitherto been possible, and it makes a great number of new forms in this favourite class of biscuit.

There are many other machines which Messrs. Baker have designed for their own use in connection with the manufacture of confectionery and biscuits, and they are all of excellent design and workmanship.

Notices of Meetings.

NEXT WEEK.

SOCIETY OF CHEMICAL INDUSTRY (LONDON SECTION).—Monday, April 21st. Papers will be read by Dr. Moritz, "On the Expulsion of Ammoniacal Compounds from Sulphuric Acid used in Kjeldahl Determinations"; Mr. Boverton Redwood, "The Petroleum Fields of India."

INSTITUTION OF CIVIL ENGINEERS.—Ordinary Meeting, Tuesday, April 22nd, at 8 p.m. Paper to be discussed: "The Application of Electricity to Welding, Stamping, and other Cognate Purposes," by Sir Frederick Bramwell. Students' Meeting, Friday, April 25th, at 7.30 p.m. Paper to be read: "Some Applications of Electricity in Engineering Workshops," by C. Frewen Jenkin.

LIVERPOOL ENGINEERING SOCIETY.—Wednesday, April 23rd, at 8 p.m. Adjourned discussion upon Mr. Thomas L. Miller's paper, entitled, "The Efficiency of Gas Engines."

SOCIETY OF ARTS.—Wednesday, April 23rd, at 8 p.m. "Coal in the South-East of England," by William Whitaker, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, April 24th, at 8 p.m. Paper to be read: "On a Lightning Guard for Telegraph Purposes, and on the Protection of Cables from Lightning," by Dr. Oliver Lodge, F.R.S.

TEXTILE SOCIETY, YORKSHIRE COLLEGE, LEEDS.—Friday, April 25th. A Lecture on "Steam Generation," by Mr. B. H. Thwaite.

PRICES CURRENT, 16TH APRIL, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: The market for copper continues very quiet, although an improvement has taken place in raw. On the 9th, the date of our last report, Chili bars were £47 17s. 6d. to £48 5s. cash, but they gradually declined till £47 10s. to £47 17s. 6d. was reached at the end of the week. The market opened at the latter rates on Monday, but a firmer tone has since prevailed, quotations to-day being £48 7s. 6d. to £48 12s. 6d. cash. But little business is taking place in manufactured, which is still quoted £61 sheets and £64 bottoms.

TIN has been very unsettled during the week, and prices are lower. Yesterday quotations for foreign were £88 5s. to £88 12s. 6d. cash; but an active trade is reported to-day at advanced rates—viz., £89 2s. 6d. to £89 10s. cash.

LEAD continues very quiet, without change in price.

SPELTER keeps easy, although there has been a little more demand recently.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—The state of the chemical markets is not satisfactory, and many complaints are being made about the quietness of business in general. Caustic soda is more plentiful, and though makers are expecting an improved foreign demand shortly, prices are giving way at present. Bleaching powder continues very dull; soda ash, however, holds a very strong position, and soda crystals and bicarbonate of soda are firm. Chlorate of potash is steady. There is less inquiry for yellow prussiate of potash. Carbolic acids continue to droop; creosote and solvent naphtha are fairly brisk. Sulphate of copper is active for April-May, but quoted much lower for later months.

RAISING A SUNKEN STEAMER.—About three weeks ago, as one of the mud-hoppers belonging to the Mersey Docks and Harbour Board was proceeding to the depositing ground at the mouth of the Mersey, it ran into the steamer "Goval," of Aberdeen, and caused it to sink over the line of the Mersey Tunnel As the wreck caused an obstruction to the navigation, the Dock Board employés have been preparing to raise, and on Monday the forward half was successfully raised and beached on the Tranmere shore. The after half will be raised as soon as the preparations are completed.

HOME INDUSTRIES.

LONDON, 17th April, 1890.

THE MONEY MARKET.—Money has now become exceedingly easy, and what little demand there is for loans, or for the discounting of bills, is satisfied at rates considerably below 2 per cent. The only disturbing element is the decline of the Paris rate of exchange to a point at which gold must leave the Bank of England. The sums sent so far to Paris have been unimportant. The stock markets are all firm and buoyant. The cheapness of money and a number of other favourable influences combined to raise prices considerably at the beginning of the week. Consols have been rising, and home railway stocks have gone up, not so much on account of their prospects, but because the public has paid little heed to the dismal prophecies that have been indulged in about an increase of working expenses concurrent with a cessation of the briskness of trade. Railway stocks have been firmly held, and "bears" who sold now find it difficult to buy stock to fulfil their commitments; hence the rise in quotations. The New York market, having awakened from the lethargy which has afflicted it for a long time, has become an active buyer, and American railway shares have been strong this week. Canadian railways are also in favour, the long-expected rise in Canadian Pacifics having taken place on the discomfiture of the "bears," who have succeeded in preventing it till now. Grand Trunks have also been bought since the issue of a favourable report for last half-year. Foreign securities are firm. Argentines, after experiencing several further severe declines, have taken a more hopeful turn. Copper mining shares have risen a little, but gold shares are neglected. Miscellaneous and industrial securities have presented no special feature.

COMPANIES.—The following companies have been registered since our last report:—Patent Lithographic Zinc Plate Co., Ld., with a capital of £10,000; George Price, Ld., with a capital of £5,000, to carry on the business of manufacturers of safes; Fowler Patents, Ld., with a capital of £36,000, to acquire certain patents for bending pipes; Ambrose Walker & Co., Ld., with a capital of £10,000, to carry on business as earthenware manufacturers; Andrews & Preece, Ld., with a capital of £25,000, to carry on the business of electrical engineers; Pomeroy Patents Gold Extracting Co., Ld., with a capital of £100,000, to acquire a certain patent for extraction of gold; The Scandinavian Exploration Co., Ld., with a capital of £50,000; The Silent Step and Flooring Co., Ld., with a capital of £10,000, to acquire certain patents; The Andrew Patent Cask Syndicate, Ld., with a capital of £10,000; William Hollins & Co., Nottingham, Ld., with a capital of £300,000, to carry on the business of woolspinners, &c.; Centrifugal Gold Process and Fine Reduction Syndicate, Ld., with a capital of £30,000; Cardiff Floating Docks and Ship Repairing Co., Ld., with a capital of £35,650; Denby Iron and Coal Co., Ld., with a capital of £30,000; Butt's Mill Co., Ld., with a capital of £10,000, to carry on the business of spinners, &c.; Kingston Phosphate Co., Ld., with a capital of £5,000; The Tilbury Portland Cement Co., Ld., with a capital of £25,000.

SHIPPING.—Freights have shown no improvement during the last fortnight, and the holidays have prevented the expansion of business. The prices of new steamers have not yet been sufficiently reduced to bring fresh buyers into the market.

THE BOARD OF TRADE RETURNS.—There has been a sudden stoppage in the favourable nature of the Board of Trade Returns, the exports for March amounting to £20,067,022, against £21,459,490 in the same month of last year. Machinery and millwork stand at £919,862, as against £920,238, but on the other hand iron and steel have advanced. Hardware and cutlery is £231,232, as compared with £274,930 in March last year. Implements and tools have increased, being £107,278, against £101,267. Cotton yarn and twist are £936,371, against £1,110,290; piece goods, £3,775,255, against £4,732,311; jute manufactures, £200,649, against £268,106; linen yarn, £73,418, against £82 161; linen manufactures, £429,534, against 486,392; woollen and worsted yarn, £288,110, against £335,949; and woollen and worsted manufactures, £1,692,015, against £1,834,386. The total of chemicals and chemical and medicinal preparations is £711,152, against £680,477, but this increase is wholly under the section of drugs. It is therefore seen that the falling off has been all along the line with but trifling exceptions. In imports a similar state of affairs exists. The total value was £36,140,334, against £36,265,387.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending the 6th inst., amounted, on 16,158¼ miles, to £1,375,901, and for the corresponding period of 1889, on 16,030 miles, to £1,222,708, an increase of 128¼ miles, or 0·8 per cent., and an increase of £153,193, or 12·5 per cent. The Good Friday week traffic income was included in the returns this year as against an ordinary week.

IMPROVEMENTS AND WORKS IN THE CITY.—Colonel Haywood, the engineer to the City Commission of Sewers, has just published his report on the works executed by that body during the past year. He states that the total length of sewers constructed during the year was 1,834ft., of which 1,031ft. were on the lines of old sewers. The number of premises drained was 160. The frontages of various premises were set back for widening streets in Aldersgate Street, Distaff Lane, Creechurch Lane, Duke Street, Milk Street, &c. The Metropolitan Board of Works used to contribute about £30,000 annually towards the cost of the improvements carried out by the Commission. The London County Council have since expressed their intention of discontinuing this practice, and they intend to deal with City improvements in the same manner that they do with those in other parts of the metropolis. Tenders were received from the Gas Light and Coke Company for lighting the public lamps, the price charged being 2s. 2d. per 1,000 cubic feet. The Commission have resolved that all the streets in the City should be lighted by electricity, and tenders have been invited. One contract for lighting the central district has been concluded with the Anglo-American Brush Electric Light Company, and others are under consideration.

THE CHANNEL TUNNEL.—An inspection of these works was made, on Saturday last, by Major Marindin. A few gentlemen and the directors of the company also paid a visit to the works. The Board of Trade gave permission for the boring machinery to be used on the occasion, provided that it was not worked until after Major Marindin had made his inspection. The ventilation of the tunnel, which is now about 2,020 yards long, was found to be perfect, and it still continues almost dry.

HER MAJESTY'S SHIP "BARRACOUTA."—The coroner's inquiry into the death of the stokers who were killed by the explosion on board H.M.S. "Barracouta" during her engine trials concluded at Sheerness on Thursday last. The jury found that "the deceased accidentally came by their death from shock from burns received in the stokeholds, caused by flames suddenly issuing from the ashpits of the port boiler, owing to the combustion-chamber tubes and tube-plates becoming overheated from shortness of water or ebullition on the boiler, thereby producing local expansion and contraction, and allowing the steam to escape into the combustion-chamber and cut off the exit of the flames through the tubes." The jury regretted that the Admiralty had not carried out the recommendations of the jury in the "Thistle" explosion in 1869, by providing hospital accommodation for injured men at Sheerness, and thus caused the necessity of sending cases to Chatham.

THE SPORTSMAN'S EXHIBITION.—This Exhibition is now being held at the Agricultural Hall, Islington. In addition to sporting exhibits proper, there are various gas engines and some light tools.

THE RATING OF MACHINERY.—Mr. Winterbotham's Bill for the exemption of machinery from rating was read a second time in the House of Commons last night. The supporters obtained a majority of 152 in a House of 326, and the general interest thus shown in the measure will probably cause the Government to take the Bill in hand.

THE "ÆOLUS" WATERSPRAY, GENERAL VENTILATING, HEATING, AND ELECTRICAL ENGINEERING COMPANY.—The goodwill of the "Æolus" Waterspray, General Ventilating, and Electrical Engineering Company, together with the patent rights, working plant, &c., have been purchased by Messrs. Baird, Thompson & Co., consulting, ventilating, heating, and sanitary engineers, of London and Glasgow, and will be carried on by them conjointly with their present business at 165, Queen Victoria Street, London, and 24, Bath Street, Glasgow. The "Æolus" waterspray system of ventilating and warming has been before the public for many years, and is well known in the United Kingdom and abroad.

MANCHESTER, 17th April, 1890.

THE IRON TRADE.—The great fall in the price of pig iron during the past few days has been followed by a fall in the quotations for bars. At the quarterly meetings last week the prices were fully maintained, and very little business was done in consequence. Quotations now are nominally £7 10s. per ton delivered, and would be lower but for the increased price of coal. There are signs, however, that the excessive rates asked for coal will be reduced, and there is already a considerable reduction in the price of coke. There is little prospect of any free buying for some two or three months. Yesterday steel boiler plates wrre offered at £9 per ton.

THE ENGINEERING TRADES.—Reports as to the condition of the engineering trades in the district are very variable in their character. Most firms are well off for orders at present, and will not actually need new ones for from six to twelve months. The new business offering is not large.

LINEN AND JUTE TRADES.—The changes that have taken place in the linen trade since our last report are principally in connection with the shipping department, which in the American quarter is brisker, owing to the extensive orders placed, and about to be placed, by buyers on the other side, in anticipation of increased tariffs. These tariffs would seriously interfere with the exports of medium and low grade linens from this country. The home trade business displays no new feature of importance. The inquiry that does exist is chiefly for a few fancy articles, or in the case of heavier fabrics for current requirements. Stocks in first hands are, notwithstanding this state of things, light, as production during the holiday period was curtailed considerably. There is a weakness in yarns which keeps prices of most classes of finished goods low, and makes buyers difficult to deal with. Damasks, and the best descriptions generally, have been inquired for, but there is not much doing in coarser makes, such as crashes and other descriptions of towelling, forfars, &c. The sales of hessians are not large, but the manufacturers may expect further orders from the large consumers here, as extensive quantities are being used for packing purposes. Linen threads are in steady request. The production of the leading concerns engaged in the trade is larger than ever and finds a ready market.

CHEMICAL EXHIBITION.—An Exhibition of samples of various chemical articles and apparatus used in the trades of this district was opened on Tuesday by Mr. Ivan Levinstein. The idea of the promoters (Messrs. Davies Bros.) is to provide a place where the various products manufactured or used in the industries of Lancashire can be examined. In this way it is thought that manufacturers will be able to ascertain what there is in the market suitable to their needs and where it is to be found. The collection at present, although small, is comprehensive, and includes a large number of samples of dye-stuffs and other chemicals. There are several samples of chemical plant of various kinds.

THE SALT TRADE.—Like cotton and other articles, the exports of salt from Cheshire for March show a great falling off. The amount exported was 35,531 tons, as against 74,161 tons in the corresponding month last year. This, coming after the prosperous months of January and February, is somewhat surprising. The owners of the salt works at Preesal, near Fleetwood, are contemplating the establishment of chemical works on the spot, so as to utilise the brine instead of shipping the salt.

SALT SPRING IN THE SHIP CANAL.—We understand that a brine spring has been discovered in the cutting of the Manchester Ship Canal near Partington. The water from the spring is being tested in order to ascertain its strength and the probable richness of the assumed salt beds. If the result is satisfactory, boring will no doubt be resorted to. Should it be proved that rich deposits of salt underlie the company's property, the importance of the discovery to the company, not only as regards the development of a salt industry, but also with respect to traffic on the canal, is manifest.

GLASGOW, 17th April, 1890.

PIG IRON.—Prices have again taken a downward turn. "Bearing" has been largely engaged in, so largely in fact that an upward turn may take place before the week closes. The stock in Connal's stores is now down to a little over 800,000 tons.

SHIPBUILDING.—An order for three large dredgers has been received by Messrs. Lobnitz & Co., Renfrew, through a London firm.—The Clyde Shipbuilding Company have granted an increase of wages to their labourers, and ended the strike.

RAILWAY AMALGAMATION.—The leading soft goods and other warehousemen in Glasgow have presented to Parliament a petition against the proposed amalgamation of the Glasgow and South-Western and North British Railways. The grounds of their complaint are that the existing competition between the two companies would be at an end, and that the North British Company would become possessed of a highly important monopoly.

PUBLIC COMPANIES.—The directors of the Tharsis Sulphur and Copper Company have declared a dividend of 20 per cent. The quantity of pyrites shipped in 1890 was only 58 tons short of the shipments in the previous year. The shipments of copper precipitate were, however, less by about 12 per cent.

A NEW BRIDGE.—The foundation-stone of the new bridge carrying the Great Western Road over the Kelvin was laid on the 9th inst. The ceremony was performed by Bailie Cumming. The earliest bridge at this point was built in 1825, a second was built in 1838, and this one having been for a long time insufficient for the traffic, it was decided in 1887 to erect a new bridge on the site of the old one. The engineers appointed were Messrs. Bell & Millar. The contract was given to Messrs. Morrison & Mason. The total cost of the structure will be £40,000. There will be three piers, the spans being, two of 91ft. each, one of 34ft. and one of 20ft. The width of the bridge will be 60ft. The arches will be of iron, and the piers will be faced with granite. The Loch Katrine water-pipes, which now run under a side extension of the old bridge, will run under the new one.

NEW DISTILLING APPARATUS.—There is about to be formed in Glasgow a new company—The Pure Whisky Distilleries (Scotland) Company, Limited—which has for its object the distilling of whisky by means of the apparatus known as the Improved Wallace Multiple Still. The advantage claimed by this process is that it renders "ageing" in casks unnecessary. The Wallace apparatus consists of a series of pot stills placed over each other. Over these is placed the rectifying portion of the still, consisting of a series of shallow evaporating trays, into each of which the alcoholic vapour that rises from the uppermost "wash" boiler is made to condense in rotation. It is claimed that the spirit produced is absolutely free from fusel oil or acetic acid, and that it is equal to that which has been maturing in casks for five years.

(From our own Correspondents.)

LIVERPOOL, 16th April, 1890.

THE NEW LIVERPOOL WATERWORKS.—There are three important works in connection with the new water supply to be completed before the Vyrnwy water can be delivered in Liverpool—the Norton tower, the Weaver crossing, and the tunnel under the Mersey at Fidler's Ferry. The tower is very far advanced, the tank at the top—which is of a

Digitized by Google

novel construction, being suspended on a series of knife-edges—is practically completed; and the Weaver crossing, consisting of a steel pipe buried in the bed of the river, and protected by concrete, is in an advanced state. The tunnel under the Mersey is, however, presenting great difficulties; and in addition to the engineering difficulties, the Council will no doubt have to face litigation, for the original contractors for the work, Messrs. Monk & Newell, will most probably have some heavy claim as compensation for not being able to complete the work on account of the alleged incorrect information as to the substrata. The work has been let to Messrs. Cochrane & Co., Westminster, and they are now proceeding rapidly with the erection of the necessary plant.

THE LIVERPOOL AND MANCHESTER MAIL COACH SERVICE.—The parcels mail service between Liverpool and Manchester was inaugurated on Monday night last, when the first coach was despatched from each place punctually at 10 p.m. The time allowed for the journey is a little over five hours, allowing for a change of horses at Prescot and Hollin's Green. In connection with this service a single-horse coach runs between Southport and Liverpool, calling at Formby, Blundellsands, Waterloo, Seaforth, and Bootle; at Warrington the mail is met by a parcel post van from Wigan.

SHEFFIELD, 16th April, 1890.

IRON AND STEEL.—The Rolling Mill Proprietors' Association have issued a circular to their customers, stating that they are reluctantly compelled to reduce the discount by 5 per cent. for all rolling done, in consequence of the increased price of fuel. The effect of this notice will be to raise the price of all rolled steel, both hard and soft. The iron market is again weaker in all branches. Steel is also quieter, and prices are slightly lower than for some time past. Ironfounders find plenty of work to keep them fully employed. Engineers continue busy in all branches.

COAL AND COKE.—The coal deliveries during the past week have been well up to the average, although there is much grumbling about the price of fuel, which is already beginning to tell upon manufacturers. Coke is reported to be easier in price, no doubt owing to a lessened demand in the North and North East districts.

NORTH STAFFORDSHIRE, 16th April, 1890.

THE IRON TRADE.—As foreshadowed in this column last week, a meeting of the creditors of a firm of local iron-masters—Messrs. Joseph Bull & Son, of the Cliffe Vale Ironworks—has been held. The unsecured creditors are involved to over £20,000, and a composition of 12s. 6d. in the pound, payable by instalments at three, six, nine, twelve, and eighteen months, was accepted. The failure was caused by heavy losses on speculative purchases of Scotch warrants. The iron trade is in a disorganised and unsatisfactory position. Specifications and orders are conspicuous by their absence, and prices have completely collapsed. The position of iron-masters will shortly be a very difficult one to support, and it is quite evident that some reduction in the cost of producing the raw materials must shortly be effected. Partly owing to the speculative mania of the closing months of 1889, and partly to the rapid enhancement of the cost of production through the action of the miners, a reaction has set in, the limits of which do not appear to have been yet reached.

THE POTTERY TRADE.—The formation of a china clay union has become an accomplished fact, and is likely to have a baneful influence on the pottery industry of this district. Orders are for the moment rather more plentiful, but, taking the trade as a whole, it is in anything but a satisfactory condition.

SWANSEA, 16th April, 1889.

EXPERIMENTS WITH "CARBONITE."—Experiments have been recently made at the Upper Cymmer Colliery which were superintended by Mr. Larsen, the managing director of the Carbonite Syndicate, in order to show the flameless character of their new explosive powder. The new material was compared with roburite and securite, both of which showed a flame after each explosion which was absent in the case of carbonite.

TINPLATES.—Stocks in the dock warehouses and vans stood on Saturday at 269,658 boxes, showing an increase exceeding 3,000 boxes during the week. Seemingly all efforts are unavailing to effect a permanent reduction, and this difficulty must continue so long as the receipts from works exceed the shipments. It has been suggested that, with the view to bring about a healthier state of this industry, after a certain date no repairs or turning should be done on Sunday, and that no mill should start before two p.m. on Monday. This alone, it is calculated, would be equivalent to a diminution of output exceeding a million boxes per annum, effected in a manner that would not be felt by either masters or men, whereas the "stop-week" system results in a heavy sacrifice for all concerned. The Tinplate Workers' Union have taken up this question in a very practical way, as they have decided to prevent the acquisition of skilled labour by companies who in the future may embark in the tinplate industry so long as the present glut in the market continues. It is not intended to take such action, however against companies having new works in course of construction. At the quarterly meeting in Birmingham last Thursday Welsh makers offered common coke tinplates as low as 14s. 6d. per box, the Midland firms, who have scarcely any stocks, quoting several shillings higher.

CARDIFF, 16th April, 1890.

IRON AND STEEL.—The fall in pig iron from what was generally expected to be the lowest it could reach under existing circumstances has taken everyone by surprise, and it would serve very little purpose to record the conflicting opinions on, and explanations of, the peculiar state of this branch of the trade. On all sides speculators have been heavily affected, and those who have been compelled to sell have been severely punished. Hematite iron is not quoted, makers knowing that the only offers they could make would be declined by buyers. Meantime stocks in stores continue to decrease, and this is one good result. For steel rails there is not much inquiry, and makers' quotations are nominal. Steel bars are £7 15s. fixed price, but it is difficult to find a buyer for a pound less than this figure. Iron ore keeps exceedingly firm; in fact, it seems the only commodity which has escaped the "bears," and from accounts to hand from Spain there is being experienced extraordinary difficulty to cope with the loading of steamers arriving. At Bilbao about seventy to eighty steamers have to wait eight or nine days before getting their turn. Rubio is quoted at 16s. c.i.f. Cardiff and Newport, 16s. 9d. Middlesbrough, and 17s. Glasgow.

COAL AND COKE.—The steam coal trade is quiet, and colliery owners are more inclined to accept the offers of buyers. It is difficult to ascertain the exact cause of the depression which has all at once come over the trade, but there can be no doubt that the position of the iron trade has its influence over coal, buyers preferring to buy from hand to mouth than to pay the high prices for fuel to any large extent. This, combined with a rather sluggish demand from abroad, has no doubt had its effect upon prices, which are about one shilling less than last quotations. The reduced prices are, however, still remarkably high, and with the contracts on hand there is nothing very disappointing in the outlook. Quotations are irregular, dependent to a great extent on the particular position of the colliery from which the coal is required, but for first qualities the price can be fairly set down at 15s. 3d. to 16s.; second, 14s. 6d. to 15s.; and inferior, 14s. to 14s. 3d. Small steam coal is easier, and the abnormally high price is now a thing of the past. It has, however, enabled some prudent colliery owners to book forward orders at very satisfactory figures. The demand for coke is fairly active, and as there are a good many special shipping orders still to be executed prices seem to be sustained.—The Dunraven Colliery, which has been valued by Sir W. T. Lewis at £130,000 to £140,000, was put up for sale on Saturday last by order of the liquidators of a Sheffield building society, but no bid was made. Negotiations for private sale are being carried on.

LEICESTER, 16th April, 1890.

WOOL SPINNING AND YARN TRADE.—Since the close of the holidays a somewhat better feeling has pervaded the wool market, but perfect confidence is a long way off yet. Supplies of the finer qualities are limited, and buyers wishing to operate extensively have had some difficulty in obtaining sufficient for their requirements at current rates. Spinners are moderately employed, but they are not eager for new business at old rates, as they still complain that prices obtainable are very unremunerative. Yarn merchants are making but a moderate turnover, and, though business is far from satisfactory, there is a feeling that quotations are more reliable.

HOSIERY TRADE.—Business is not very brisk, and the slackness of trade has been influenced by the week's holiday to a large extent. Yet, though trade is so quiet at present, there is a feeling of confidence that the coming season's trade will be good.

BOOT AND SHOE TRADE.—All the manufactories are very busy, so much so that the holidays were somewhat curtailed. There are plenty of orders on hand, and they still come in freely. The outlook is extremely cheerful. Leather merchants are doing more new business since the holidays, and are making a satisfactory turnover.

BARROW-IN-FURNESS, 16th April, 1890.

HEMATITE PIG IRON.—There has been a further depression in the hematite pig iron trade. The demand seems to be vanishing altogether, and as there are prospects of a further decline in prices buyers are withholding what few orders they have to give. Makers have done next to no business during the week, and there have not been any heavy transactions in warrant stocks. Stocks are still large, but they are less than they were in the beginning of the year. Warrant prices have gone down to 53s. 6d. per ton, but makers are still unable to produce iron at less than 65s. per ton. Several furnaces are soon to be blown out. There are now fifty-two in blast, and twenty-seven out of blast.

IRON ORE.—There is less life in the hematite ore trade, and some of the mines are running short of orders. Three months ago there was such a full demand for iron ore that the native production could not supply smelters with their requirements, and Spanish ore was largely imported. Now mine owners are looking out for orders, and, in view of a further restricted production of pig iron, ordinary qualities of iron ore can be bought at 11s. 6d. per ton, although the general quotations in the district range from 12s. 6d. to 17s. 6d. per ton net at mines.

MIDDLESBROUGH, 16th April, 1890.

PIG IRON.—The market is once more in the hands of operators, who have deranged the prices, to the surprise and no small chagrin of makers and others interested in a steady, legitimate trade. The price of No. 3 has been lowered 5s. per ton with the week. No. 3 G.M.B. is down to 47s., and has been sold as low as 46s. 6d. At the market held yesterday there was great depression of spirits at the sudden turn. At first 48s. was quoted, but the fall in the Scotch market, as telegraphed, brought down the price at once, though it rallied somewhat towards the close. The stock in Connal's store is still decreasing. On Monday it stood at 139,359 tons. The decrease during this month is already 12,477 tons. East Coast hematites are nominally 70s. per ton f.o.b. for makers' iron mixed numbers, but the low price of West Coast hematite must bring down the figure considerably.

SHIPMENTS OF PIG IRON.—The shipments are fully maintained as far as the foreign demand is concerned, but have fallen off seriously in the home demand. Up till Monday the shipments of pig iron from the port of Middlesbrough for this month amount to 38,802 tons, as against 21,694 tons to a similar date last month, and 48,219 tons to the 14th of April last year. Connal's stores are still being heavily drawn upon for shipments on account of the difference between warrants and makers' prices.

MANUFACTURED IRON AND STEEL.—In finished iron there is a decided lull, and few inquiries come to hand. Prices have fallen fully 2s. 6d. Iron ship plates are at £6 10s.; angles, £6 7s. 6d.; common bars, £6 12s. 6d. per ton; steel ship plates, £7 10s.; angles, £7 10s.; rails, £5 15s. per ton, all less 2½ per cent. on trucks at manufacturers' works.

NEWCASTLE, 16th April, 1890.

SHIPBUILDING.—The falling off of shipbuilding orders which began to be felt towards the close of last year is now affecting work in the Tyne yards. At one large establishment, out of six available building berths only one is occupied. A few of the leading yards, however, are well stocked with work, and workmen discharged from one establishment find no great difficulty in obtaining employment at another. Should the present dearth of orders continue, however, there can hardly fail to be a scarcity of employment before the end of the year, and at present appearances seem to indicate that such will be the case.

ENGINEERING.—Contracts for replacing compound by triple expansion engines in old vessels have been obtained by more than one engineering firm on the Tyne, but in respect of engines for new vessels, inquiries, for some time past, have been exceedingly few. In the locomotive engineering shops of Newcastle and Gateshead business is fairly active, a considerable part of the work on hand being ordered on foreign account. At the North Eastern Railway shops a new compound engine is being got ready for the Edinburgh Exhibition, and will be sent away in time for the opening day. It is most elaborately finished, and will no doubt be found to be one of the most attractive objects of the show.

THE COAL TRADE.—Owing to the stoppage of collieries for the Easter holidays, the shipments of coal and coke at Tyne Dock for the week ending April 12th were considerably below the average, the figures being 80,626 tons.

BELFAST, 16th April, 1890.

SHIPBUILDING.—Work in the shipyards is now progressing favourably, there having been no disagreement between the masters and men for several months. There is still a large amount of work in hand, and there are several other keels to lay. No new orders, however, have been placed here since the new year, and inquiries are still very scarce, and are likely to remain so as long as wages and material remain so high. Much satisfaction is felt here at the splendid maiden voyage of the new White Star liner "Majestic," which last week completed the run from Queenstown to New York in six days ten and a half hours, being an unprecedented record for a maiden trip. Marine engineers and boilermakers continue busy, and have a large amount of work in hand.

LIGHT RAILWAYS.—A deputation has arranged to hold an interview with the Commissioners of Public Works on the subject of the amalgamation of the Finn Valley and West Donegal Railways, and an effort is being made to obtain powers to construct a narrow gauge railway on the eastern side of the Foyle from Strabane to Derry. These, with the other light railways already in hand, will open up a country hitherto almost inaccessible.

LINEN TRADE.—Business continues fair and stocks are keeping low, while prices remain firm. Inquiries for cloth are numerous, but there are no stocks in hands as makers are still working up past orders. The supply of home-grown flax is now almost exhausted. A local paper gives the capital invested in the linen business in Belfast at £18,250,000, a sum which will give an idea of the great importance of this industry to Ulster.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 18TH APRIL, 1890.

LABOUR MOVEMENTS ON THE CONTINENT AND AT HOME.

On the 1st of May, in Germany, Austria-Hungary, Switzerland, France, and Spain, unless the respective Governments interdict—and some have shown discouragement—there will be an international holiday, and a workmen's demonstration. It would be useless to disguise the fact that labour on the Continent is in a state of ferment. Excited meetings are being held in every European capital, violent harangues are being delivered where they have hitherto been wont to result in violence of another sort. In Paris and in Vienna the police and the agitators have already come into conflict, and the beginning of May is being looked forward to with much anxiety in both capitals. In Germany the great strikes of last year conveyed the unmistakable lesson that labour combinations had taken root. What may be called English ideas have been long in developing; but there can be no doubt that this development has begun, and that, once the German workman suspects how strong he is, he may be trusted to use his strength, perhaps too exclusively to his own advantage. German industry has been far behind; in some industries their technical methods are perhaps superior to ours, but in many they are quite archaic, and the prevailing temper of mind of the employing class is similar to the unbending and arrogantly selfish temper of the typical English employer of the early part of the century. The autocratic character of the Government, too, and the excessive fostering of the military spirit, have had their share in retarding the emancipation of the German working class. These latter elements also have practically determined the character of German industrial ideals. The Germans are, in effect, a nation of State Socialists. They are accustomed to live and move in rank and file. They prefer to be told what to do, and they do it with all their might. One need not infer from this that German policy is quite destitute of originality; but it is at least remarkable that Germany has almost always followed where others have led, and where it has not been led by foreign nations it has been led by foreigners. The recent Labour Conference, with its slight tangible result, was the first incident in the attempt of the Emperor William to seize the "slowly creeping lion" and to tame him to his own uses; whether the lion will be satisfied, and will submit to the grasp upon his collar, remains to be seen.

The recent industrial history of this country is rather different from that of Germany. We passed through the State-Socialistic phase in the later Middle Ages, and have since thrown off a good many of the shackles forged by it. We may have to go through a similar experience again; but Germany is a new nation, and may probably have to pass through an acute phase of it, which, contagious as it is, we may be able to escape. While the attitude of the State towards labour in Germany is partly one of fear and partly one of patronage, and while the attitude of our own Parliamentary Government is not very different from this, our public opinion is, in other regards, far in advance of German. The strident attitude of German employers towards labour and labour questions is, by common consent, out of date in this country. We have become, at least in theory, extremely eclectic, and, without risk of losing the esteem of our friends, may even subscribe to strike funds or aid in the formation of trade unions. We have, indeed, proceeded some distance along the path of voluntary ungovernmental industrial organisation, while the Germans seem resolved to try the other, the path of industrial control by the State. We have, it is true, trodden also in this latter path, but its inadequacy has of late years become too obvious, and Germany and the other Continental nations who seem disposed to follow our lead may find that they have erred, as most imitators err, in pursuing an abandoned method. The conception of the function of the State which prevails in Germany, as declared in the Rescript of the Emperor William, involves the domination by the State of the industrial life of the people, and this method of industrial organisation may be that best suited to the genius and habits of the people; but in England this conception has never in recent times been more than a "pious opinion." Of late years, with us, statesmen have been more or less guarded in extending the State functions, and have rarely done so without vigorous protests from some one who saw whither the pursuit of such a plan would lead. It might well be argued, however—German character and German industrial history being what they are, with military traditions and characteristic readiness to submit to external control—that State regulation and management of industry would likely suit the nation so well that they might with propriety be adopted, at all events as a temporary expedient.

And if the Fates are propitious, it may be that ere long we shall have the spectacle of a practically autocratic Government establishing an industrial State inside of a military one. It seems, indeed, within the bounds of possibility, that what would amount to a Socialist State might be established in Germany, whose enormous military power might suffice to defend it against all comers, or even impose it on the rest of Europe. This is admittedly far-fetched, but its realisation does not in the least depend upon the emancipation of the people, for this must be a slow process; but solely upon the continued enslavement of them and the binding of them more rigorously than ever into an iron routine. On the other hand, if, instead of copying the industrial legislation of England, whose effects, on the whole, have probably been bad, the Germans set themselves to copy the voluntary organisations which are far more powerful than governmental ones, and which form the most effective barriers against the encroachments of these upon personal freedom, Europe will be rid of a possible and serious danger. The bearing of these considerations upon the question of shorter hours is not remote. If in any industry it is found, on hygienic or other grounds, that the hours of labour are too long, it is surely wiser that those who carry on that industry, employers and employed mutually of course, should come to a common understanding, spontaneously, as to the number of hours during which work should be carried on, rather than that an arbitrary number of hours should be fixed by Act of Parliament. For the State to step in and determine the number of hours during which a man or woman should work is not only a serious infringement of personal liberty, but in many cases might result in a practical diminution of the level of comfort of the class whose benefit it is intended to secure. Unless it can be shown that compulsory shortening

Digitized by Google

of hours will not have this effect, it would be hard to make out a case for it. The shortening of the hours of labour, and the consequent diminution of the production, in the case of a commodity like coals, where the bulk of the cost consists of wages, is a very different matter from the case of a commodity like cottons, where the bulk of the cost of production is interest upon capital. The effect upon the cost of production, and through that upon prices, is different in each case, and thus substantial injustice to the working classes themselves would be done by the arbitrary fixation of their hours of labour by statute. So long as the members of a trade, employers and employed, acting together by common consent, determine spontaneously to diminish the number of their hours of labour, but little objection can be laid against their so doing; their action might lead to hardship among the rest of the community, but it has been found almost impossible to devise any general statute to prevent such inconvenience arising. But when such a body is compelled by an external authority to work such a time, and such a time only, we find ourselves back in the days when our clothes, our food, and our journeys were controlled by statute; in which a man's life was not his own—but the king's. If the miners are desirous of working only eight hours a day, if the general conditions of the trade require this and this alone, then their unions are surely weak if they cannot make an effective claim of this kind. The miners, with their strong unions and their naturally powerful position, standing as they do at the source of industrial motive power, ought certainly to be strong enough to maintain any reasonable claim either for reduction of hours or advance of wages. On the Continent, the incohesive character of the working class may meantime perhaps not improperly employ the State to secure an immediate accession of strength to their position; but with us the danger of the future is not that the working class may have too little power, but that it will have too much prematurely. Even if it were granted that the organisation of industry is defective on many points, it is by no means to be held as proved that an organisation, or even a regulation, imposed in obedience to pressure from below would be any less productive of social inconveniences and inequalities than the regulation that now is. With all its faults, it has spontaneously arisen without State domination, or at all events with comparatively little of it. Some have advocated a plan whose adoption would at any rate have the advantage of not being compulsory. This is the extension of the system of working in "shifts," with the view of utilising the machinery for even a longer period than is customary, while securing the employment of individual workers for even shorter hours than as at present. The only valid objection to this plan is the probably excessive work which it might cost the managers and foremen, though this, perhaps, might be obviated. There is no reason why mines should not be worked on a three-shift principle; the cost would not be greater, and the men would be fresh instead of jaded. Alert study of such methods, and enlightened adaptation of them to the special needs of particular cases, must yield results vastly more fruitful than arbitrary and ill-considered general legislation. No one can suppose that an Eight Hours Act for miners would be a final settlement even for them, and it is at least doubtful whether it is a step in the right direction. All the indications are the other way. The question is not exactly a party one; but although there are not the usual party prejudices to reckon with, for or against, the circumstances of the case render it unavoidable that the subject should have been discussed, for the most part, in a sentimental fashion. Hyde Park demonstrations are not quite the best arena for the discussion of a question which is, after all, in the main, a scientific one. If each person who has influence on the decision frankly put the questions, What are the ostensible grounds for the passing of such a Bill? and What are the probable effects of its passing? there is little doubt that the Bill would be thrown out. Amid the clash of opinions one point emerges most clearly, and this is, that the passing of an Eight Hours Bill would still more definitely tie up our industry in official routine, which over and over we have found wanting, and would be a fresh prostration of ourselves before the fetish of Government. It requires some courage for those who depend for their political existence upon the favour of the working class to stand up and say that an Eight Hours Act would injure them, but it is worth doing, for the gain of the passing moment is not worth the risk of the throng of troubles such a measure would bring in its train.

EMPLOYERS' LIABILITY BILL, 1890.

On previous occasions we have reviewed the whole question of the liability of employers for injuries to their workmen from an independent standpoint, having regard to the incidence of a fair pecuniary compensation on the one hand and the restriction imposed on industrial operations on the other. Last year an attempt was made by Parliament to amend the Act of 1880, but the Bill had to be abandoned at the close of the Session. A further effort in this direction is being made by the Government, who have introduced a Bill with the above title, the main provisions of which we propose to summarise. While the various sections of the first clause, which deals with the cause of action, have been somewhat amplified, they would not materially alter the working of the Act of 1880. Briefly, it may be said that in case of proof being given of any defect in the condition or arrangement of the works or plant, or of negligence on the part of a person entrusted with superintendence or the delegation of orders, or of any person controlling locomotion, the employer is liable. The mixed question of liability in case of work being done by contract is settled in the second clause, whereby an action will lie against the contractor or the principal, but not against both. With regard to contracting out of the Act, which is general in some mining districts, the Bill provides that all such contracts shall be void unless made in pursuance of a request in writing from the workman and for a consideration which, in the opinion of the Court trying a case, is sufficiently substantial to justify the workman for depriving himself of his legal rights, and which must be other than that of entering upon or remaining in the employment. The time in which notice may be given of injury to a workman has been extended from six weeks to three months, and no action commenced in the County Court can be removed into a superior Court except by mutual consent, unless the compensation claimed exceed £100. The amount of compensation recoverable under the Bill is a sum equivalent to three years' earnings or £250, whichever is larger. Where compensation is awarded in case of death the judge is empowered to apportion the amount awarded between the wife, husband, parent, and child of the deceased. The operation of the Act is extended to seamen.

An effort will be made to insert a provision in the Bill making employers liable for an accident caused by the wrongdoing or negligence of any person in his employ, thus removing the defence known as that of "common employment." We have no hesitation in condemning such a proposal. An employer cannot be expected to govern the actions of all his workmen, and the limit of his pecuniary liability in case of their default to those to whom he directly entrusts the duties of superintendence is a just one. Under the above proposal, were it clearly demonstrated that a miner fired a gaseous mine by an act of wilful disobedience to the rules of the colliery, and that many lives were lost by an explosion in consequence, the colliery proprietor might be held liable.

We always deprecate any legislative proposals which tend to the promotion of litigation and ill feeling between employers and their workmen, and, in the case of the dangerous occupation of mining, would much prefer to see a system of mutual insurance, contributed to by both masters and men, than frequent recourse to law.

THE "CITY OF PARIS."

We have been informed that when the "City of Paris" was being examined in the graving dock at Birkenhead, on Friday last, an incident occurred which seems to clearly explain the cause of the breakdown of the engines. When the casing in which the propeller shaft revolves was opened the end and intermediate sections of the shaft, along with the propeller, dropped into the dock below with a terrific crash, cutting the heavy beam of timber which forms the floor of the dock right through with one blade, while another, which struck the stone of the dock, was curled up by force of the impact. It seems, then, as if the cause of the accident was the breaking of the propeller shaft, which would of course make the engines run at a tremendous speed and knock the ends out of the cylinders. The theory of water in the cylinders, which was put forward when the breakdown was first heard of, is thus disproved. In any case, whatever further investigation may show as to the cause of the disaster, there can be no doubt that if it had not been for the watertight bulkheads a most terrible catastrophe might have resulted.

ELECTRIC LIGHTING OF CHELMSFORD.

Chelmsford is the first town in England to be lighted throughout by electricity. The inauguration of the new system took place on Monday last, in the presence of a large and distinguished gathering.

The contract for the public lighting of the town was given to Messrs. R. E. Crompton & Co., Limited, of Chelmsford, who have carried it out by putting down central station plant at their works. The boiler capacity of the works has been increased, and a special vertical engine, by Messrs. Marshall & Co., of Gainsborough, has been put down in the building devoted to the lighting plant. With light loads at any time during the day, or in early evening, the works plant is used; and when the main lights come on, the special vertical engine is started, driving its own plant, and the works plant then remains as spare. This arrangement is exceedingly economical, as the shop engines are naturally running in any case, so that the expense of keeping a special day engine going, as is otherwise necessary in alternating current systems, is avoided. Changing over from one engine to the other is, of course, done without any stoppage, as the alternators can be put in parallel. If a serious accident, such as a broken crank pin, were to occur, about five minutes would be needed to change over, as one engine would be cold, and would require to be warmed up. This delay is only unavoidable in case of a sudden and total breakdown, such as that mentioned. The dynamos are all belt driven. The arc lights are on direct current series circuits, and the incandescent lamps are run from transformers in parallel. There are 18 arc lamps of 1,500 candles nominal, run from series wound, smooth commutator arc lighters made by Messrs. Crompton & Co. We should have thought it better to arrange the arc lights either in series, or in parallel with choking coils on the alternating circuit, but many people hold that an alternating arc gives a lower efficiency because the power is split over two craters, so that the temperature of each is somewhat lower, and, therefore, the light of each much lower. Moreover, the lower crater is rather wasted, as it radiates its light upwards into space.

The lights and wires are generally on one side of the road, but in the chief street they are on alternate sides, the leads being taken across underground. There are 210 incandescent lamps of 32 c.p. each, from 45 to 75 yards apart. These are hung in lanterns 16ft. from the ground on graceful brackets fixed to the poles. The lamps are in groups of 12, each group having its own transformer. The incandescent circuit is fed by Mordey alternators. There are four circuits for the public lighting, and four for the private consumers. There are about thirty miles of overhead conductor, and about 250 yards of Callender's bitumen casing where underground work has been necessary. The connections between the overhead and underground conductors have been made by lead-covered cables inside hollow iron standards. The overhead wires and lamps are mounted on neat pitch pine poles fixed to iron sockets which are set into 4ft. 6in. of concrete. The wires are hung on steel bearers at a minimum height of 25ft. The whole of the wiring arrangements are designed in perfect taste, and have a light and graceful appearance. The Board of Trade rules are adhered to throughout. In fact, the entire installation reflects the greatest credit on the contractors, and on Mr. A. H. Pott, who has engineered it, and borne the brunt of the work.

We also had an opportunity of going over the Messrs. Crompton's Arc Works, which are at present exceedingly busy. They have been enlarged, and have the neat, orderly, and business-like appearance of a well-managed factory. The works manager, Mr. Hayward, is introducing the interchangeable system more or less on American lines. All the parts are ordered from the works by the stores in quantities, and a dynamo has no individuality until its parts are given out to be erected. On the English plan a machine or engine has its number as soon as it is ordered from the drawing office, and the various parts are made from the beginning to this number.

In the evening a public dinner, with the Mayor of Chelmsford in the chair, was held to commemorate the inauguration of the public lighting of the borough. There were a great many very complimentary speeches, and general satisfaction was expressed all round.

Letters to the Editor.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

Sir,—The opening paragraph of Messrs. Hughes & Lancaster's letter in your last issue on the subject of the low-pressure tramcar system is rather self-contradictory, for whereas they state in one line that it can be applied to any existing roadway "without any alteration whatever," they say in the next that it is necessary "to lay the air main under the footway with branches across to the valve boxes." It thus appears that they draw a distinction between pulling up the centre of a street and pulling up the sides; the fact, however, is, that before the system can be applied a trench has to be dug all along the route. This does not matter greatly, however, if the system proves economical in its working. The figures given in the table are interesting, but will be more valuable when verified in practice on any of the lines which have been tendered for. I trust that Messrs. Hughes & Lancaster, when any of these lines have been fitted and have been running for a few months, will publish the actual cost and working expenses, together with the estimate already quoted by them. Any means of saving, combined with efficiency, is sure to be welcomed by tramway companies.

With reference to the statement that it is impossible to obtain reliable data as to the cost of electric traction, this, if it be accurate, ought to be set right in the interests of electric traction people themselves. On the Barking line, I understand that the Electric Traction Company, Limited, are under contract with the North Metropolitan Tramways Company to run the cars at 4½d. per car mile, including the wages of the drivers and conductors. The average of the working expenses of the four lines tendered for by Messrs. Hughes & Lancaster comes to 4·4d., so there is but little difference under this head on the average. The question, however, arises as to whether the Electric Tramway Company are making a profit or a loss on their contract. As a further means of comparison, the results of the working of the Northfleet line by the Series Traction Company would be welcome; it has been running for some time now, and figures may possibly be procurable.

Yours, &c.,
CAR.

Portsmouth, 12th April, 1890.

THE LONDON ELECTRIC SUPPLY CORPORATION, LIMITED.

To the Editor of "Industries."

Sir,—If the Deptford Electric Light Station proves a failure owing to the cables not being satisfactory, there is no doubt that it will have an injurious effect on the public mind as regards electric lighting in general. For this reason, if for no other, it is to be hoped that Mr. de Ferranti will succeed in carrying out his original scheme, but Mr. J. S. Forbes, the Chairman of the London Electric Supply Corporation, in his recent speech to the shareholders, was somewhat unsatisfactory. He stated that the mains which have proved unfit for their duties were not designed by Mr. de Ferranti, but in concert with Mr. de Ferranti, and that they were carried out by a great manufacturing firm. They were, according to the lights possessed by this particular firm, calculated to do a certain thing. They were to be tested up to 10,000 volts, and they were tested up to that, and beyond. Among other things they had to find out was that there was a great difference between tests in the laboratory and after the things were put in the earth. 10,000 volts was in excess of anything they had to stand, and if they had been able to stand half of 10,000 they would have been considered to perfectly answer the purpose for which they were conceived and laid. Unfortunately, however, they did not. Mr. Forbes would not go farther into that matter, as it was possible that they might have to resort to law to recover damages for unworkable construction or want of skill. With reference to the question of permanent mains, plenty of mains had been laid for low tension, but for high tension Mr. de Ferranti, among other things, had invented his own main—or what is called the permanent main—and that main had been manufactured and tested, as far as a test could be applied on a limited length of it, on the company's own premises, up to 2,000 volts; and what Mr. de Ferranti predicted was this—that whatever the reason of the defects might have been in the particular main constructed and laid, which had failed, these permanent mains were so different in the principles of construction that they would not fail.

The whole of this is very unsatisfactory to an electrical engineer. What we want to know is, who was responsible for the design of the faulty cables. Mr. Forbes admits that Mr. de Ferranti partly designed them, and the suggestion is that the makers did not fulfil the conditions imposed. It is also suggested that the makers in question are incompetent manufacturers. The concentric tubes of Mr. de Ferranti have been described in various journals, but it does not appear whether the faulty ones are those which he designed "in concert" with the manufacturing firm or whether they are those which are now being constructed. The remark that the company might sue the makers in the Law Courts is one of those indefinite assertions frequently made by chairmen at company meetings, but in justice to other central station engineers it should be stated who are those cable manufacturers who do not carry out instructions and who turn out bad work. Giving the name will not, I take it, subject Mr. Forbes to an action for libel if he already intends to bring the law against them for non-fulfilment of contract.

Yours &c.,
F. S.

London, 12th April, 1890.

PAYING CHEQUES BY TELEGRAPH.

To the Editor of "Industries."

Sir,—In your issue of the 28th of February, page 194, you were good enough to describe and illustrate my method of sending pictures by telegraph, and I now desire to put forward a scheme for paying cheques by the same agency. Permit me to state, then, as regards the utility and the practicability of transmitting cheques, or, in other words, of making payments by telegraph, that such a scheme should prove of material benefit to the commercial world.

The question of making payments by telegraph by means of the telegraphic postal order has ere this been suggested. This, in many instances, may no doubt prove a great boon to the general public. But the fact of being able to make payments by telegraph through our bankers, and with less fear of fraud than attends the ordinary process of cheque payments, should prove a step towards the advancement of commercial enterprise, for a cheque thus transmitted would bear upon it a talisman verifying its validity, and thus render such a document payable at sight. It is not necessary here to enter into a description of the process through which a cheque must pass, and the time required before the receiver of the same per post from a distance is made cognisant as to the said cheque being honoured by the banker upon whom the same has been drawn, as my purpose is simply to show how payments may be made without fear of fraud or unnecessary delay by means of telegraphic communication.

First, let us suppose that a firm in Manchester, Glasgow, or any other provincial town find it to their benefit, or perhaps essential, that they should complete by speedy payment a business transaction with another firm in London, New York, Melbourne, or, in fact, in any city in the civilised world possessed of bankers working in connection with our English bankers, and to which communication by telegraph is established. Such a payment might with safety be completed by telegraph in the following manner:—In the first place a telegraphic form (which I would have supplied by the bankers only) should be used, and, after being duly filled in by the payer, it should then receive the bankers' signature, and also the impression of an embossed design specially prepared for this service. This form on being presented at the telegraphic office would not only ensure its despatch, but would qualify the report on reaching the receiving station being duly committed to a similar form and signed by the postmaster or other authorised person. This being done, the document, on receiving the impression of a facsimile of the bankers' embossed design, would be rendered complete for delivery at the bankers appointed for the cashing of the same, and would by the telegraphic messenger be delivered to the bankers, while to the party to whom the cheque is made payable would be delivered a duplicate in part of the substance of the cheque—that is to say, an ordinary telegraphic form containing the amount of the cheque and the name of the place where sent from, leaving out the names of the sender and the receiver, it being understood that the receiver would know the name from whom such an amount was expected. In exchange for this duplicate the messenger would take a receipt from the receiver, as in the case of a registered letter. On presenting at the bank this duplicate, and furnishing the names of the sender and the receiver, a receipt would be signed by the receiver, and the handwriting of which corresponding with that of the receipt received by the telegraphic messenger (which of course would be delivered by that functionary at the bankers') the receiver would then obtain the money from the bankers. This method is suggested for the use of those transmitting payments from the provinces.

The method suggested for the metropolis would be to have one central station for the discharging of cheques and for the issuing of telegraphic cheques to those having accounts with provincial bankers and not banking with any London bank. At the London office a registry of the signatures of all persons entitled to transact business in this manner would be kept. No person except those entering themselves as members or subscribers to be permitted to transmit cheques by telegraph. The signatures of provincial and foreign subscribers might be furnished to the London office through their bankers in the following manner:—The signature would be written by the subscriber on a small form, the back of which being prepared with an adhesive substance (such as that on postage stamps), and, as a proof of the authenticity of such signatures, the form should also receive the signature of the banker, and be impressed with the embossed telegraphic seal before mentioned. On reaching the London office the signature of the subscriber would be cut from the form, and carefully stuck in its alphabetical place in the reference book of signatures. The issuing of telegraphic cheques at this London office would be a simple matter, as none would be issued but to those having accounts with provincial bankers, and telegraphing payments to be discharged by such provincial bankers except when the payment was to be made in a foreign country. In this case, on receiving an advice by telegraph from the banker of a certain person wishing to make a payment abroad, then a telegraphic cheque would be granted. Hence the security against fraud, as the signature of a payer would be checked at the London office before the cheque was despatched, and the question as to balance or the discretion as to over-draft would rest with the bankers discharging the cheque.

Yours, &c.,
H. Rickinson.

57, Compton Road, Highbury, London, April 14th, 1890.

THE PROPOSED FORTH AND CLYDE CANAL: ITS IMPORTANCE—NATIONAL AND INTERNATIONAL.

To the Editor of "Industries."

Sir,—At a time when such desperate efforts are being made to reduce the time and length of voyage to America, perhaps I may be allowed to refer to a matter of importance in this and other respects which a lengthened study of the subject has evolved. The matter in question has reference to a proposal to construct a canal between the Forth and Clyde, opening communication for vessels of the largest class between the east and west coasts of Britain, and which would also be of the greatest importance in the communication of the east coast with the continent of America, and, *vice versâ*, of the West with the continent of Europe. The latest proposal for shortening the voyage from this country is for the establishment of a route between Milford Haven and St. Charles Bay, near the Straits of Belleisle, on the Canadian coast, by which it is expected that the time from land to land will be reduced to three days thirteen hours. Referring to a notice of this in a London paper, I pointed out a plan whereby, according to the calculations in the proposal referred to, the voyage could be still further reduced to about three days. I also showed whereby steamers to London and the east coast of Britain could avail themselves of this advantage by adopting the route *viâ* the proposed canal.

My wish is now to point out not only the advantage to London, the east coast of England, and the middle western States of Europe, which, as a means of communication with America, the opening of the proposed canal would provide, but also to show the importance that it or such another waterway would assume, as a means of intercommunication with the shores of Britain itself. As regards the latter part of the subject, perhaps it is from being accustomed to it that such a state of things have been allowed to remain for so long. But it does seem strange that a mercantile power of the magnitude of Great Britain should remain indifferent to maritime intercourse between her own coasts. One might as well undertake a voyage to the capital of Portugal as go from Liverpool say to Hull by sea. By either the northern or the southern route a voyage of ovey 1,000 miles would be required to reach the places named, although separated by little more than 100 miles. The same fact applies in a lesser degree to numerous other places on the British coast. When consideration is extended beyond these, the deficiency presented is quite as glaring. From the east coast of Britain to the Irish coasts a long detour either north or south is necessary. From the west coast to the Continental countries bordering the North Sea and the Baltic, the same is applicable. In the direct communication of these countries with America, Britain blocks the way in some instances to places as far south as New York. Would not, therefore, such a means of communication as the proposed Forth and Clyde shipway be a real desideratum, saving, as it would, distances reckoned by hundreds of miles, and also providing a direct intercontinental route? That such a route, either betwen the Forth and Clyde, or the Solway and the Tyne, will be opened sooner or later there can be little doubt, and the sooner those concerned in either of the routes are alive to the importance of the matter the better. The enterprise of Manchester, given it sufficient time, might also find ways and means of bringing about such a desirable result in her own locality, backed as she would be by the immense manufacturing interests of that part of England, which it might be expected would give the proposal the utmost encouragement.

Continental nations, too, when the shortest route, the Forth and Clyde, is considered, may be expected to give the matter some attention. As an alternative route to America to that by the English Channel and Southampton, the proposed route offers several advantages; amongst others, that of enabling fast steamers to land passengers from America with the shortest possible sea voyage. This could be accomplished by Broadhaven (at present without railway communication), on the wes coast of Ireland, and in the line of the northern route, being made a port of call. From New York the advantage of quite a day would be gained by the adoption of this route, compared with a call first at Southampton. Broadhaven is situated, in respect of distance from Kingston, very much as Queenstown is. Even landing at Greenock there would be a much shorter sea passage than to Southampton, and the time from New York to London, *viâ* Greenock, would practically be the same as *viâ* the southern port. The distance between New York and Hamburg is very much the same by either route, that *viâ* the canal being the shorter, but the difference in its favour might be allowed for the time which the passage of the canal would occupy. For trading vessels the advantage which a cheap supply of coal on the route *viâ* the canal would afford (the line of route being through the midst of an extensive coalfield) might be an additional inducement for them to use it.

The importance of the canal in communication between the Canadian ports, the east coast of Britain, and Europe will be apparent. Even should the extreme short sea passage project talked of not be carried out, the whole of the other Canadian ports would be benefited, and Halifax especially, a port open all the year round, and already adopted as the port of destination for a line of swift steamers in connection with the Canadian Pacific Railway. When the efforts that are being made to divert traffic from the west of Chicago *viâ* Canadian ports are considered, the importance of the canal in this direction cannot be lightly estimated.

Considered in all its varied aspects, the question of the communication under review is one bristling with importance, and the wonder is that a nation like the British, with such mighty interests in maritime and naval affairs, should have remained so long apathetic to a matter so intimately concerning herself and her own best interests. The practicability cannot be doubted, and the cost, it has been shown, will be such as to put it on the basis of comparison with a local enterprise, which one enterprising city in the kingdom has tackled almost single-handed.

If there is the matter of dividend in the one, the other must be a splendid affair—and from an exhaustive study of the matter the writer is inclined to think it will, should the matter be considered in all the aspects of construction which it is capable of presenting.

I give the following as the calculation of the time from Chicago which the journey by the proposed new Canadian short sea route will occupy compared with present time to Liverpool:—

Viâ New York.	Dys.	Hrs.	*Viâ* St. Charles Bay.	Dys.	Hrs.
Chicago to New York	0	23½	Chicago to St. Charles Bay	1	23
New York to Liverpool	6	8½	St. Charles Bay to Milford Haven	3	13
	7	8		5	12

To Glasgow the time would be—

	Days.	Hrs.
Same as Milford Haven	5	12
Passage of canal (as recently estimated)	0	8
The canal to Hamburg	1	12
	7	8

The time from Chicago to Hamburg, *viâ* the canal, would thus be the same as to Liverpool at present.

Yours, &c.,
"Eon Strathaar."

London, April 16th, 1890.

SMIT'S COMBINED ENGINE AND DYNAMO.

TO THE EDITOR OF "INDUSTRIES"

SIR,—In reading the description of the Smit combined engine and dynamo, illustrated in *Industries* last week, I was much struck by the remark that "Messrs. Smit have used an open engine instead of the closed-in type, and thus have sacrificed efficiency, durability, and freedom from breakdown."

I note Messrs. Smit's little engine has a 4in. cylinder, 5in. stroke, and runs 450 revolutions per minute, with 100lb. to 150lb. pressure. I presume "the closed-in type" means one of the numerous arrangements of small single-acting engines now in the market, which are mostly all boxed-in, although there are some double-acting engines arranged in that way. If Messrs. Smit had adopted a single-acting cylinder of the same diameter the engine would have to run at 900 revolutions, or if the same speed as now was kept with a single-acting cylinder double the area of piston and double strains on the parts would be necessary for the same power, so I fail to see where the superior efficiency, durability, or freedom from breakdown would come in; probably it would be the other way. The single-acting engine has the advantage that, the push being in one direction, there is no noise from slack bearings; but as to freedom from breakdowns, perhaps it is because these single-acting type engines are either subjected to double strains to compensate for being single-acting, or else are set to run at undue speeds for the same object, that they are more than any other type noted for smash-ups.

Yours, &c.,

AN ENGINEER.

Bolton, April 14th, 1890.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the nineteenth ordinary meeting of the session, on Tuesday, the 15th inst., Sir John Coode, K.C.M.G., President, in the chair, the paper read was on "The Application of Electricity to Welding, Stamping, and other Cognate Purposes," by Sir Frederick Bramwell, Bart., D.C.L., F.R.S, Past President Inst.C.E.

Although large structures of wrought iron and of mild steel commonly had their parts united by bolting or by riveting, and although much ingenuity had been expended in so arranging and proportioning riveted joints as to obtain, in the joint, the greatest percentage of the strength of the material, nevertheless cases occurred in all structures where the union of these metals by welding became almost a necessity, or if not a necessity, a matter of convenience and economy. Wrought iron, in addition to its many other merits, had the merit of being, *par excellence*, the weldable metal; mild steel also possessed this merit; but nevertheless there was always a feeling of doubt about a weld, although welds were of necessity largely trusted. No better illustration of this could be given than that of a common chain, each one of its manifold links having a separate weld. In the early days of making suspension bridges, the links, unless the wasteful process of cutting away a large portion of the bar was resorted to, were made by forming the eyes separate from the bar, and by welding them on. To obviate these difficulties, as long ago as 1845 Mr. Howard, of the firm of Howard & Ravenhill, of the King and Queen Ironworks, Rotherhithe, devised a plan which, while avoiding the necessity of welding on the eyes, avoided also the waste of material before alluded to. Within the last few years a plan of "upsetting" the ends of the bars by mechanical means, so as to obtain the requisite material for the formation of the eye, had been introduced in the United States. Although imperfection in a weld might arise from insufficient heat, or indeed from an excess of heat, or from the application of inadequate power to bring the heated surfaces together, probably by far the greater proportion of defective welds arose from the presence of some foreign body between the surfaces to be welded, or, as it was expressively called, "dirt" of some kind or another. Attempts had been made to obviate these difficulties, by employing gaseous or liquid fuels, and, in rare cases, by the removal of the oxide of the metal from the surfaces, by turning or planing. Allusion might be permitted to the welds that were successively employed for the welding of railway tires in the days prior to the present system of making these tires by continuous rolling, and in the hoop form. These comprised an ordinary scarf weld, bird-mouth welds in both directions, single-wedge welds, and double-wedge welds. In all these cases hammering was employed: but for carriage tires, at all events, the butt-weld was used. In the early days of wrought-iron ordnance, where it was desirable to have in one piece a wrought-iron tube so long in relation to its diameter that it would have been difficult to have welded it up as a single coil, it was made by welding two coils together, each of about half the length of the desired tube. It need hardly be said that everyone of the modes of heating employed involved that the heat should proceed from the outside inwards. There were also the chances of inadequate heat; of an excess of heat; and, as had already been stated, of the presence of "dirt" in the weld. Moreover, there was the difficulty of ascertaining to what state the heat had attained; commonly in small welds the pieces were withdrawn from the fire, with the consequent risk of picking up "dirt" during re-introduction. Among the desiderata for heating for welding purposes, the mode adopted should admit of uniform heating throughout the sectional area to be welded; it should admit of absolute regulation of the heat; it should be free from the possibility of introducing either particles of fuel or gases between the welding surfaces, and it should admit also of complete inspection during the time the heating was going on. All these desiderata were afforded by electrical heating. As regarded the power of an electric current in passing through substances to develop heat, the most familiar instance was probably that of the carbon filament of an incandescent lamp, now so largely used in theatres, in clubs, and in private houses. It was common knowledge that electrical energy was compounded of electromotive force or potential, or preferably "pressure," multiplied into the amount of the current, or the pressure multiplied into the quantity. Whenever this electrical energy had to pass through a conductor, the resistance of that conductor to its passage destroyed a certain portion of the electrical energy, which energy so destroyed reappeared in the form of heat, and must appear in the very conductor which had been the cause of the destruction of the electrical energy. Therefore the amount of heat produced must be that which was the thermal equivalent of the electrical energy destroyed. What the temperature would be, and in most cases it was the temperature reached by the conductor, as the result of the passage of a given quantity of current, which was of importance, depended not only upon the heat-units produced but upon other considerations. Although electric energy was represented by the multiplication of the pressure into the current, it would be found that the heating effect of any given current was independent of the pressure, and that the heat produced was in proportion to the current employed. As regarded the heating effect of any given current upon different materials, if there were an absolutely perfect conductor, which offered no resistance to the passage of an electric current, no amount of electrical energy could heat it, because no extent of conductor could destroy any part of that electrical energy. On the other hand, in the case of a material absolutely impermeable to an electric current, it need hardly be said that no heating could result, as no current could pass. Fortunately the materials commonly welded, iron and steel, held a very happy position as conductors in the scale of metals for the purposes of being electrically heated. The electrical resistance of metals increased, however, with an increase in their temperature. This question of the increase of resistance due to increase of temperature had been investigated by Dr. Hopkinson, and the results obtained had been published in the Philosophical Transactions for the year 1889. This increase of resistance to the passage of the current, as the temperature increased, was of great utility in electrical welding. Consider the two ends of bars to be welded, mere ordinary rough surfaces, the first contact was made upon numerous points, through these the current passed, and they became rapidly heated, and offered more resistance. As endway pressure was applied the surfaces in contact became of larger and larger area, until all were heated up uniformly. The greater current sought those parts which, although in contact, were at a lower temperature, and this went on until contact and uniform temperature were obtained. Having regard to the fact that the particular form of electrical energy needed for imparting heat was that of large current and low pressure, it would be seen that there was very great difficulty, amounting almost to a commercial impossibility, of transmitting electrical energy in such a form over any but very short distances, for, unless the conductors were of enormous size, they themselves would be injuriously heated by the passage of the current; and, moreover, the pressure required to drive these large currents through any considerable length of conductor would be so large a percentage of the working pressure as to add very greatly to the power required. For these reasons it was desirable that the electrical energy should only take the form of large current and low pressure in the very neighbourhood of the welding machine itself. In all probability the great use of electric welding machines would be for uniting pieces of special and difficult form, and for dealing with refractory metals, refractory in the sense that they did not lend themselves to successful welding by any of the ordinary processes. Metals which had been dealt with in such machines comprised:—

Steel.—Every variety seemed to be weldable.
Iron.—Cast, wrought, malleable, case-hardened, ferro-aluminium.
Copper.—Cast, rolled, drawn.
Brass.—Cast, rolled, drawn.
Delta metal.—Muntz metal.

Aluminium.	Tin.	Cobalt.
Silver.	Lead.	Manganese.
Gold.	Zinc.	Bismuth.
Platinum.	Nickel.	Iridium.

Bronze.—Aluminium, phosphor, silicon, &c. Gun-metal.

Gold to platinum.	Bronze to iron.
Iron to steel.	German silver to iron.
Brass to iron.	German silver to brass.
Copper to iron.	Copper to brass.

At the Crewe works, Mr. Webb had one of these welding machines in use. He had it at work at present "shutting" on eyes to screwed rods of some ⅜in. diameter; the weld was made close up to the screw, which was in no way injured in the process. It had also been employed to weld ends to tubes, to weld together the parts of twist drills which had been broken, and to weld best steel for tools on to commoner materials. It was obvious that a machine that gave the power of heating any material with an absolutely controllable heat, and that enabled that heat to be inspected and to be communicated without the advent of impurities, must have many uses in the arts, in preparing pieces for brazing, for stamping, and in a variety of other ways; in fact, there could be no doubt that the existence of such a machine would itself give rise to a large number of new uses.

HALF-A-CENTURY OF AUSTRALASIAN PROGRESS. By William Westgarth. London: SAMPSON LOW, &c. 1889.

In taking stock of the progress which we are making at home it is very necessary that we should also make ourselves acquainted with the advances which are being made by the Colonies, for progress can never be measured in absolute measures, but only in relative. Our own progress in every department has during the past fifty years been immense, but when we compare it with that which has been made by our Colonies, in some respects it seems small. The book we are about to notice is one of the best we have seen for giving some idea of the progress which has been made in Australasia during the past half-century, and its author, Mr. Westgarth, has been able to give his personal experiences over the whole of that time. He first went to Australia in 1840, where he resided until 1857, when he returned to London, where his business required him to keep up his interest in the Colonies, and in the volume before us he has given the public the results of his long experience in commercial and financial affairs, and his opinions on a very large number of questions, all of the highest interest to merchants and statesmen.

The first part of the book, and the most generally readable part, is taken up with a personal retrospect, and an account of the author's travels, but it differs very much from an ordinary traveller's book. Along with an account of what he sees he gives his experience and observations on many varied subjects, and there are few pages which do not contain some points which will be of value to a large variety of readers, while the whole account forms a most valuable guide even to an ordinary traveller. Our space will not allow us to enter into details, but we can recommend its careful perusal to our readers, as well calculated to afford a great deal of useful

Digitized by Google

information. It is, however, the second part of the book to which we wish specially to direct attention, as it is taken up with the consideration of questions which are now being carefully studied by statesmen, as well as by all who are interested in the industrial development of the Empire. He discusses such questions as the prospects for a still further improved service of intercommunication between England and Australasia, the policy of the Empire's extension, the socio-political principles of the Empire's Government, Intercolonial Federation, or the federating of natural colonial groups into one Government, the political unity of the entire Empire. He even makes suggestions for a monarchic-democratic peerage of the Empire. On each of these subjects he has much to say that is well worthy of study, when Imperial Federation is believed by some statesmen to be the most important problem of the day. So rapidly does the problem advance that he has written a long preface, which is of the nature of a postscript, bringing all the points up to the date of the publication of the book. He dwells on the importance of Imperial Federation, which he says is undoubtedly the greatest, as well as the most urgent, question of the day. He finds that the colonists are desirous to be united, or to remain united, with the great Empire of their fellow-countrymen; but as soon as suggestions are made for bringing about a closer connection than exists at present differences of opinion arise. They dislike the idea of an Imperial Executive overshadowing them, they dread a Parliamentary rule which is over their own, they are nervous even about a federated English Cabinet. Mr. Westgarth thinks that these objections arise in great part from the utterly anomalous position which the Colonies have held for the past thirty-five years, in being practically their own masters, and yet, while on their part responsible for nothing, full members of an Empire every part of which the mother country is bound to cherish and defend. He thinks the equities of the case are well exemplified in the apostolic argument about the body and its members. In the colonial case each member thinks to live for itself, because that is so safe and pleasant under the powerful shelter of the whole body, and yet each is grudging and jealous of the strength which it is to contribute thereto. We do not know that we can agree to all the proposals made by Mr. Westgarth, but we feel that he has given a most valuable contribution to the literature of the subject, and taken an important part in that discussion which must precede all legislative action. We, however, thoroughly agree with the results which he says would flow from a well-considered scheme of Imperial Federation. He points out that if we had an imperial policy in which the colonial element duly weighs we would probably steer still more clear, if possible, of foreign complications than has been the later steady aim of our Home Government; that when the power of the whole Empire is grasped by an adequate and constitutional Executive, every section of it, even the least, is assured that in case of need the whole Empire stands behind it; and lastly, when the rest of the world realises this new position of the Empire, the prospect of any attack from other Powers will be materially diminished. Such a united Empire would be of the greatest value in advancing industrial and commercial progress, and in solving the most important economic problems of the day, but it would also, practically, rule the destinies of the world, and that always for good.

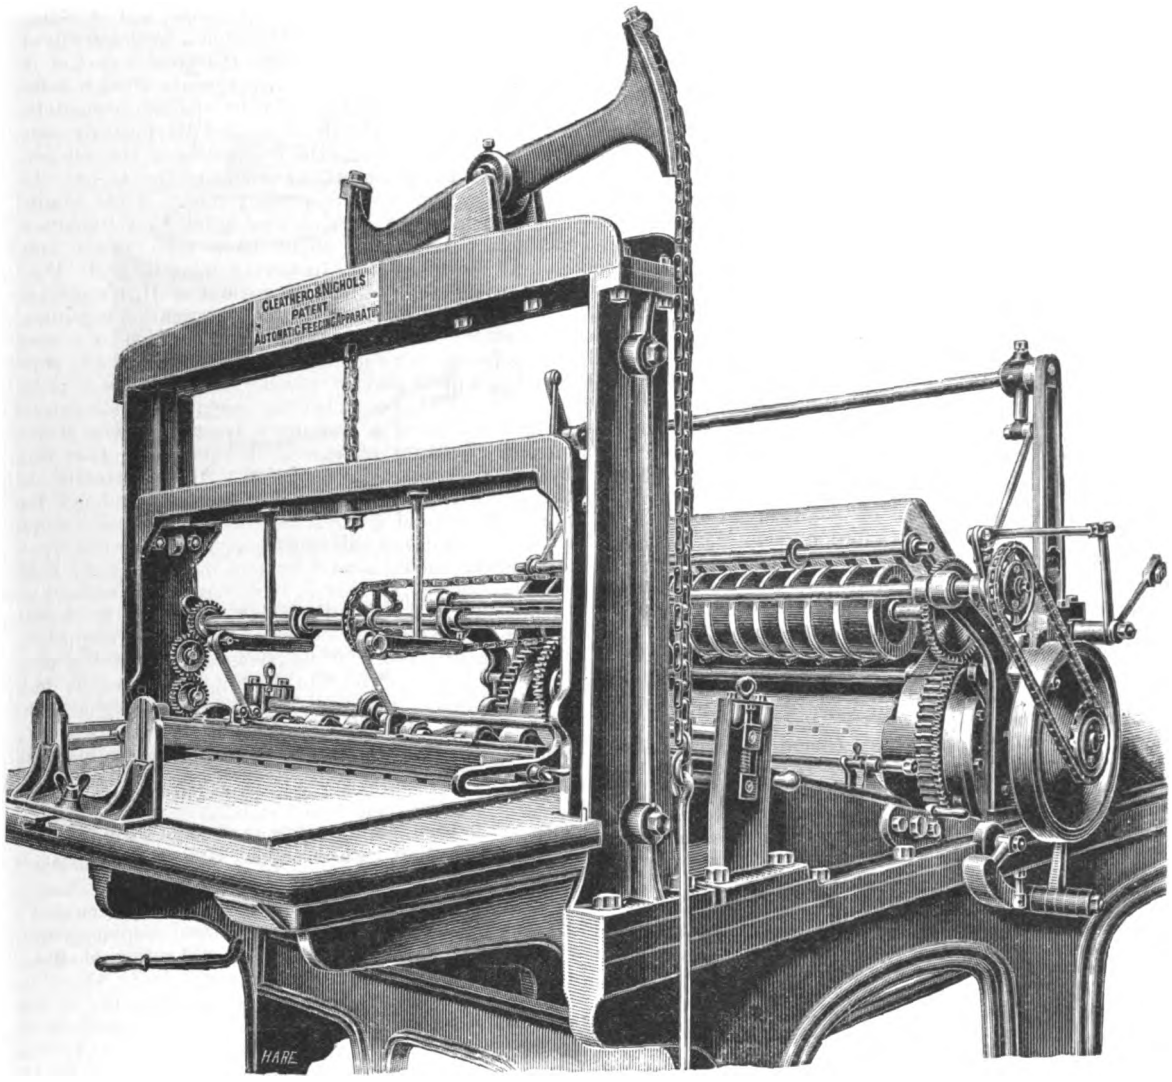
THERMODYNAMICS OF THE STEAM ENGINE AND OTHER HEAT-ENGINES. By Cecil H. Peabody, Associate Professor of Steam Engineering, Massachusetts Institute of Technology. London: MACMILLAN & Co. 1889.

In previous notices of books on the steam engine we have made the remark that *the* textbook on this subject had still to be written. Our present object is to ascertain if that has been produced by Mr. Peabody. The methods of treating the subject have hitherto been very varied. The ordinary or popular method is to make a considerable number of assumptions, and then to reason as if these were well-established truths. Theory of this kind is apt to be very misleading unless its limits are distinctly mentioned, which, unfortunately, they seldom are. Then we have the mathematical treatment, which is chiefly useful as an exercise in the application of mathematics, but which by itself leads to few useful results. Then, again, we have a combination of the popular and the mathematical methods, with a slight addition of information regarding the physical properties of the steam used and of the materials of construction. These three methods may be looked upon as stages in the evolution of the theory of the action of steam in engines. When, however, he has got thus far, the young student may be led to study the writings of Hirn, and there he will be informed that, in the present state of our knowledge, a theory of the steam engine is impossible, and that we must depend almost entirely on the results of practice. He will naturally then ask himself, What is the use of all the mathematical work in which I have been engaged? and he may find it difficult to obtain a satisfactory reply. Should he, however, come across such a book as Professor Cotterill's treatise on the steam engine, he will be pleased to find that it is possible to combine his mathematics with a considerable amount of practical experience. But that book is only a first step in the direction of providing a complete theory of the subject with which it deals, and, moreover, it does not put its results in such shapes as enable the engineer to utilise them. This is a point which is too often forgotten by writers on engineering subjects. They ought to remember that, however deep they may go into theory, or however interesting they may make their discussions of the results of experiments, unless they show their bearings on the ordinary practice of engineers, almost all their work is in vain.

Mr. Peabody says that his work is designed to give instruction to students of technical schools in the methods and results of the applications of thermodynamics to engineering, and, while he has considered it desirable to follow commonly accepted methods, his treatment differs from that of other writers, either in substance or in manner of presentation. The general theory or formal presentation of thermodynamics is that employed by the majority of writers, and was prepared with the view of presenting clearly the difficulties inherent in the subject, and of giving familiarity with the processes employed. However, in the discussion of the properties of gases and vapours, the original experimental data on which the working equations, whether logical or empirical, must be based are given fully, in order to afford an idea of the degree of accuracy attainable in calculations made by their aid. Rowland's determination of the mechanical equivalent of heat has been adopted, and with it his determination of the specific heat of water at low temperatures. The author's "Tables of the Properties of Saturated Steam and other Vapours," which we noticed shortly at the time they appeared, were calculated to accompany this work, and may be considered to be an integral part of it. The first nine chapters form a very concise statement of the facts and mathematics of thermodynamics, and are very well suited to the purposes to which they are intended—that is, for use in technical schools. The two main laws are stated in a very distinct manner, and the deductions from them are clearly worked out, and without any display of unnecessary mathematics. There is nothing, however, very original about the treatment, and those who are acquainted with the French and German treatises on the subject will recognise the origin to which a considerable amount of it is due. The chapters on the flow of gases and vapours, and on the injector, present some novel features, especially in the comparisons with experiments.

All this, however, is merely preliminary to the main object of the book, which is the treatment of the problems connected with the steam engine. Mr. Peabody states that he has deemed it advisable to avoid all approximate theories based on the assumption of adiabatic changes of steam in an engine cylinder, and instead to make a systematic study of steam engine tests, with the view of finding what is actually known on the subject, and how future investigations and improvements may be made. For this purpose a large number of tests have been collected, arranged, and compared. Special attention is given to the investigations of the action of steam in the cylinder of an engine, and considerable space has been given to Hirn's researches, and to experiments that provide a basis for them. Directions are given for testing engines, and for designing simple and compound engines. This is all very well in its way, and is a considerable advance on the majority of previous writers, but still there is the want of a connection between all the theory of the earlier part of the book and the experiments of the latter part. The young student may well ask, "Why give a treatise on the steam engine an imposing look by crowding it with mathematics unless you show its application?" and with much reason too. Mr. Peabody does occasionally use some of his mathematical results, but he makes no attempt to develop a complete theory founded on the experiments he quotes and on the mathematics which he employs, and in this respect his treatise is defective. He, however, gives a great deal which will be found useful. In Chapter XII. he gives the theory of an engine which works in a Carnot cycle, and compares the results with those obtained from Hirn's experiments. He, however, explains clearly the position he takes in the matter, which is more than most writers on the subject do. He points out that a complete working theory of the steam engine should take into account the differences from the Carnot cycle, as well as the action of the walls of the cylinder, the incomplete expansion and compression, the losses from radiation and friction, and the effect of the clearance or waste space at the ends of the cylinder. He enumerates the theories of Rankine, Clausius, Jenner, and others, and points out wherein each is deficient, and he considers them as first approximations, without which the existence and amount of the error would never have been known, and he points out that at the present time a complete theory cannot be stated, as the form even of the factors depending on the thermal action of the walls has not been discovered, and all attempts to introduce such factors have led to unsatisfactory results. The proper direction of investigation therefore appears to him to be to determine the action of the walls quantitatively, in engines of different forms, and working under different conditions. Although a large amount of experimental information exists the greater part of it cannot be used, because the experiments, though sufficient for the purposes sought by the experimenters, fail to give certain essential data, and Mr. Peabody says that this, together with the complexity of the subject, has made all attempts to complete the theory unsatisfactory up to the present time. While admitting the force of all this, we think that Rankine's method of treatment might have been taken and brought down to date. Instead of doing that, Mr. Peabody enters into a rather full account of Hirn's method of analysis, and gives much useful information regarding the methods of testing steam engines, which of course will be found very valuable by all students of the subject, but a great part of which would be more in place in what might be called an engineering laboratory handbook than in a systematic treatise on the steam engine. Treatises of this kind have very often sins both of omission and commission. An ideal treatise on the steam engine, intended for engineers and not for physicists, should contain no theoretical work except what is used in the subsequent applications, while these applications should always be put in such a form that engineers saw at once how they were to be utilised in their daily work. Mr. Peabody's work will be found most useful to students as well as to practical engineers, and in many respects is in advance of what has previously appeared, at least in the English language; but notwithstanding that, we feel that more might have been made of the materials at his command. In short, we feel that *the* treatise on the steam engine has still to be written.

THE STEAM ENGINE AND THE INDICATOR. By William Barnet Le Van. Philadelphia: HENRY CAREY BAIRD & Co. London: E. & F. N. SPON. 1890.



This book will be found a most useful supplement to the more systematic treatises on the steam engine, giving, as it does, an account of the theory and action of steam in engines in language which is intelligible to the ordinary student, and at the same time conveying a vast amount of information on points which is only to be gained by practical experience. It is intended chiefly to be a guide to the use of the indicator, and as such is now the most complete treatise of the kind in the English language, and also the one which contains the greatest amount of information on the applications of the indicator to the most recent forms of steam engines. Those who are acquainted with the older books on the subject will recognise how much the author is indebted to them, but they will also recognise that he has availed himself of the resources of the engineering periodicals both in Britain and America, as well as of his own practical experience, to bring his present work up to date. Some years ago Mr. Le Van published a small volume on the Steam Engine Indicator, in Van Nostrand's Science Series, which consisted chiefly of matter which had appeared in the American *Mechanical Engineer*, and which was very well received by engineering critics. Since that time we have observed that he has been a very constant writer in American scientific journals, so that the present book is the result of long and careful study, and of a great amount of practical experience, extending, as he tells us, over a period of more than thirty years, and is therefore worthy of a careful and favourable consideration.

The historical introduction may be thought by some to be unnecessary in a book like this, but we have a strong leaning in some cases towards the historical treatment of any subject, as it is only when a student understands how a thing came to be what it is that he fully appreciates what it is. Unfortunately history is too often written with a national or a personal bias, and on the steam engine it cannot be denied that British writers have as a rule paid too little attention to the claims of American inventors. It is probable that it will be found that Mr. Le Van has given too prominent a position to the latter. He has at least given evidence of the existence of the "Savannah," which anticipated the "Sirius" and the "Great Western" by nearly twenty years, and dispelled the idea that the whole story of its crossing the Atlantic was a myth. After a chapter taken up with an account of the properties of steam, and its action in the

Digitized by Google

AUTOMATIC FEEDING APPARATUS FOR PRINTING MACHINES.

CONSTRUCTED BY MESSRS. CLEATHERO & NICHOLS, LONDON.

cylinders of engines, we have a chapter on "Horse-Power" as an introduction to the main subject of the book, and in connection with that a considerable amount of useful information is given regarding apparatus, and methods of application and calculation, in each case illustrated by concrete examples which cannot fail to make their meanings clear to the readers. Then follows an exhaustive description of the various parts of the indicator diagram, with examples of the various peculiarities to be met with in practice, and a comparison with correct diagrams, by which we are able to diagnose the faults of the engine. The next three chapters may be looked upon as containing the theory of the steam engine in non-mathematical language, and will be read with profit even by mathematicians. The action of steam jackets is explained in a very clear manner, and their uses and abuses pointed out, and may be read with advantage at the present time when the question is now being actively discussed by engineers. The longest and most important chapter in the book is that which treats of the different varieties of steam engines, and especially the methods of treating their indicator diagrams. Our space will not allow us even to enumerate the various points and designs discussed; it is sufficient to say that, not only are the applications to the older forms fully considered, but also the most recent developments in land, marine, and locomotive engines. A special chapter is devoted to gas engines, in which a sketch is given of their action and of the methods of applying the indicator to their different varieties. Chapter XV. is taken up with showing the superiority of the automatic cut-off engine over the positive cut-off engine, and shows that in many cases the coal consumption of the latter is very often double that of the former. The concluding chapter gives a considerable amount of miscellaneous information, especially regarding the leakage of steam engines, while an appendix gives descriptions of the most recent forms of indicators, and tables and formulæ relating to steam. If we have any criticism to make on the book as a whole, it is that its arrangement might be improved and its matter placed in more logical order. As it is, however, we have no hesitation in stating that it contains a great amount of information which will be useful to engineers, and we have much pleasure in commending it to our readers.

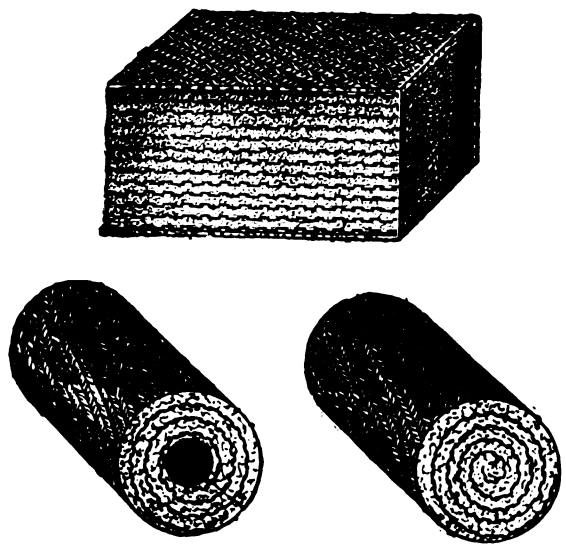
NAVIGAZIONE; NAVIGLIO. Per Salvatore Raineri. Estrallo dall' Enciclopedia delle Arti e Industrie. Pubblicata dall' Unione Tip. Editrice Torinese. 1889.

Whatever diverse opinions may be entertained in this country regarding the practical knowledge and skill of our Continental neighbours as builders of ships and engines, there can be but one opinion as to their keen and intelligent interest in all that is progressive in these important industries. The work named at the head of this notice forms a striking example of the closeness and intelligence with which the various steps in advance are followed by Italians. "Navigation" and "Navy" are two articles republished under one cover. They originally appeared in the Italian *Encyclopædia of Art and Industries*. The writer of this work is Captain Salvatore Raineri, already favourably known on the Continent through his "Storia tecnica e annecdotica della Navigazione a Vapore" and other works. His long practical experience, and especially his present eminent position of technical secretary to the vast shipping concern "Navigazione General Italiana," qualifies him to write with discrimination and authority. It is not very often that anything so comprehensive and, at the same time, so exhaustive on essential points, has come under our notice as these articles, which, together, form an excellent compendium of existing knowledge on the extensive subjects they deal with. Every available source, apparently, has been requisitioned for authoritative information, and many valuable tables are given, while a conspicuous feature of the work is the number and beauty of the illustrations. Many of these are full-page engravings both of vessels and engines recently built for merchant and war purposes in Italy as well as in this and other maritime countries. The author's treatment of the subject of navigation is very comprehensive, concerned as it is with everything relating to the movement of a ship from port to port. In addition to an historical sketch of the subject, he describes the most approved modern methods of navigation and seamanship, and the various appliances, charts, and books involved. Propulsion by sail is next considered, theory and actual practice receiving due attention, and an exhaustive record is made of noteworthy performances by celebrated clippers and modern yachts. Steam navigation is then dealt with historically and critically, and here the author is on firm ground, his official position and experience enabling him to throw much light on steamship performances. The subject of economy in speed and coal consumption is thoughtfully discussed, and much information is given, both in the form of tables and plans, of steamships belonging to the principal companies of the world. Not the least interesting of the many illustrations given is one which is unfamiliar, if not quite unknown, to English students of marine inventions, this being the screw propeller of Leonardo da Vinci, from which it will be seen that a share of the credit attaching to the invention of this propulsive agent must be accorded to this old time authority.

The article "Navy" is necessarily, in some measure, a duplication of "Navigation," but is concerned more with the construction than with the management of ships. The art and science of naval architecture from ancient times down to the very moment of writing are traced in a most comprehensive and instructive way, the letterpress being much assisted by copious illustrations. The construction of vessels of war is illustrated by engravings of some of the principal ships of the Italian Navy, together with a few typical vessels belonging to other countries; while torpedoes and torpedo boats are duly described, and the book appropriately concludes with the tabular statements of the amount of shipping, &c., owned in the chief countries in the world. As a book of reference on all matters pertaining to the history and present state of shipbuilding, shipping, and navigation, Captain Raineri's work is admirable, and a feature which adds much value to it is the copious and well-arranged lists of original sources of information enabling those whose who may wish or require full details to know where to find them.

AUTOMATIC FEEDING APPARATUS FOR PRINTING MACHINES.

THIS apparatus, of which we give an illustration above, has been devised by Messrs. Cleathero & Nichols, 23, Manchester Avenue, Aldersgate Street, London, E.C. It is attached to the end of a Wharfedale printing machine on the premises, though it is applicable to any class of cylinder machine. A difficulty that has been found in automatically feeding printing machines is that sometimes more than one sheet is fed in at a time. This is overcome in the present apparatus by having a shaft, the rollers of which are shown near the front of our illustration, in which, by a backward revolution, the sheet of paper uppermost is caught by segmental fluffing rubbers of cushion shape, and raised from the underlying sheet. By means of gearing of ingenious arrangement, the same shaft is then reversed and other segmental rubber-covered rollers carry the paper forwards. The first operation allows air to get underneath the required sheet of paper, which is then fed over tapes to the grippers of the printing machine. The driving power of the feeder is taken direct from the machine, so that, though the speed of the machine may be varied, the supply of sheets of paper is in unison with its printing capacity. For the same reason there is no over-inking.



The pressure on the shaft is regulated by a chain, at the end of which there are weights suspended: the chain is shown about the centre of our illustration, the weights being attached below, and the thicker the paper to be operated on the greater is the weight applied.

The apparatus can be attached to any existing machine, and no extra floor room is required. It dispenses with the labour of the "layers on," saves time, and is more accurate than hand labour. The patentees, one of whom is an engineer and the other a practical printer, claim that they have an absolute and certain feeding of a single sheet to each revolution of the cylinder, an increased amount of work done, a saving in labour, as already said, and an absolute register. The last named and most important feature is attained by the ingenious application of the shove register attachment, mostly used on litho machines for colour work.

A NEW ENGINE PACKING.

Messrs. David Moseley & Sons, Chapelfield Works, Ardwick, Manchester, have introduced a new engine packing, to which they have given the name of "Duriflex." The object of the manufacturers has been to combine the durability of a metallic packing with the flexibility of a fibrous packing, and in their efforts to attain this combination they appear to have been generally successful. It is especially applicable for marine work and for other cases where long engine runs are a necessity. For such purposes it has, in the opinion of the several engineers running in vessels to the Black Sea, shown itself superior to any other packing, and it is about to be used in the famous liners "City of Paris" and "City of New York."

The packing, it will be seen, is constructed of wire gauze and a fibrous material such as asbestos or cotton, and, from the nature of its construction, it follows that it must possess the qualities of durability and flexibility in a great degree. It may be constructed in any form, and with or without an indiarubber core, but the forms represented in the engravings are generally used. In the engravings the wire gauze is indicated by the thicker black lines. This is prepared before insertion in the packing by cutting or corrugating it diagonally and by placing it between the layers of fibrous material with the corrugations diagonally arranged. By this means the rigidity of the wire gauze is entirely destroyed, and the packing has practically as great a flexibility as engine packing made entirely of fibrous materials.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At a meeting of this Institution, on the 10th inst., Mr. W. F. Melhuish read a paper "On Signalling Across Rivers in India," of which we give the following abstract:—

It not unfrequently happens that a river cable fails entirely, or becomes imperfect at a time when, owing to the force of the the stream, a new cable cannot be immediately laid, or when there is no ready-made cable available, or when a considerable period must elapse before the new cable can reach the river. To provide for these contingencies attempts have from time to time been made in India to signal across rivers without cables. Three different methods appear to have been discussed and attempted, viz.:—1. Signalling through an imperfectly insulated wire. 2. Signalling through an ordinary bare wire. 3. Signalling without any metallic conductor.

During May, June, and July of the year 1888 Mr. Johnston made a long series of trials across the canal and the river Hooghly, and the subsequent measurements and experiments led him to come to the following conclusions, viz.:—That up to 1½ miles it is perfectly easy and practicable to signal through a bare wire under water; that for greater distances, judging from experiments, it is not possible to signal in this manner. In April, 1889, Mr. W. P. Johnston died, and the duties of electrician were entrusted to me. I resolved to change the class of signalling apparatus and to continue the experiment. Discarding continuous steady currents and polarised receiving relays, I adopted Cardew's vibrating sounder. I began from the beginning, and tried to signal across a waterway without a metallic conductor by laying down two earth-plates on each of its opposite banks. Readable signals having been exchanged, the distance separating each pair of plates was varied with the view of ascertaining how close the plates might be brought together, the signals remaining still readable. Readable signals were exchanged when the distance separating the plates was equal to the breadth of the river, reading becoming more difficult as the plates were made to approach each other, and clearer and more distinct as the distance between the plates was made to exceed the breadth of the river. I learnt from these experiments that in order to obtain signals of sufficient distinctness for the practical purpose of transmitting messages, it would be necessary to construct a line on each bank of a river much longer than the breadth of the river; and as the rivers along the coasts in India are extremely wide, I became impressed with the impracticable character of such an undertaking, and decided to strike out a new line. This new line was the laying of two bare uninsulated iron wires across the waterway parallel to each other, and separated by a certain distance, the ends on each bank being looped together by means of an insulated conductor. Hence, though much of the circuit was laid under water, it was nevertheless a continuous metallic circuit. Beginning first with a complete square by laying the wires as many yards apart as the river was wide, signals were instantly exchanged that were incomparably louder than those that were exchanged when the same area was bounded by four earth-plates. The length of each of the two wires under water was next gradually increased to 740 yards, and the distance separating them gradually diminished to 35 yards, the strength of the signals diminishing proportionately, and ceasing to be readable when the wires were further prolonged. The conclusion arrived at from these experiments was that for the practical and useful purpose of signalling messages across a broad river in the absence of an insulated cable, a complete metallic circuit was at least desirable. Acting on this conclusion, it was sought to apply it practically, and the following experiment was carried out:—At a distance of 15 miles west of Calcutta a cable is laid across the river Hooghly, which at this point is 900 yards wide. The iron guards of this cable were employed to form one of the metallic conductors, and at a distance of 450 yards down stream a single wire, weighing 900lb. per mile, was laid across the river to form the second metallic conductor, insulated land lines having been run up to loop the two parallel conductors together. The experiment was quite a success, the signals being readable without difficulty.

The local line from the Central Office, Calcutta, to Garden Reach is about four miles in length, and at about midway the wire spans a small river. Vibrating sounders having been put in circuit at each end of this line, the wire where it crosses the river was taken down and laid along the bed of the waterway. Signals were loud and clear at both ends. From the success of this experiment it may be inferred that on any ordinary line, should the wire from accidental causes come off the insulator and make earth by touching the bracket, standard, or ground, or should the wire break and both ends of it be lying on the ground or in a watercourse, communication could still be maintained by means of the vibrating sounders.

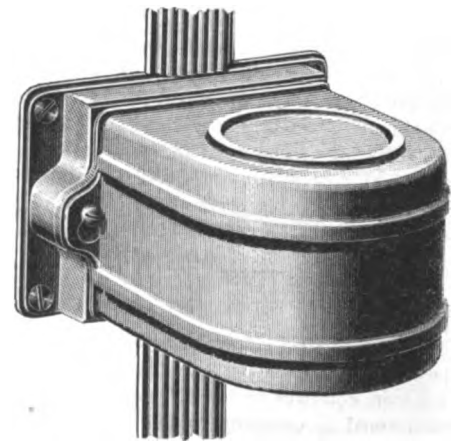
The line wire which connects the town of Chandernagore with Barrackpore is about 10½ miles long, 900 yards of which consists of a cable laid across the river Hooghly. Vibrating sounders having been joined up in the telegraph offices at Barrackpore and Chandernagore, the insulated conductor of the cable was thrown out of circuit, and the line wire on each side of the river was joined to the iron guards of the cable; thus for a length of half a mile out of 10½ miles the conductor was wholly under water, yet it was found quite feasible to transmit messages between the two offices. From the success of this experiment it may be reasonably inferred that in the case of certain cable crossings where the rivers are not too wide, should the copper conductor of the cable make dead earth or become insulated by parting, communication could still be kept up between the two offices on either side.

Each of these three experiments may properly be described as a delicate experiment. With so much of the conductor under water, the quantity of current which reaches the receiving telephone is so infinitesimal that signals could not be successfully transmitted if the vibrator were joined up in the ordinary manner. It is desirable in circumstances similar to these to reduce all the resistance external to the actual connecting lines to as small a quantity as possible, and therefore, when messages are being transmitted, the telephone at the sending end should be removed from the circuit, as also should the vibrator from the receiving end.

In the discussion which followed this paper, Major Cardew said he did not consider himself entitled to much credit for his sounder, as similar instruments had been used by others before him. The idea of obtaining communication by bare wires as mentioned seemed to him good, and he thought copper wires would be better than iron ones. In addition to the armour of cables being used as a local talking circuit, it was easy, he said, by using the vibrator, telephone, and small condensers, to talk along the main conductor without interfering with the through traffic.

General Webber considered the questions dealt with in the paper of considerable importance in practical telegraphy. The life of river cables in India was, he said, very uncertain, due in some measure to the great variations of depth which the rivers undergo; in some cases the depth changes from 5ft. to 60ft. in a single season. Sounders for signalling without wires were employed some years ago in signalling across the Solent between Hurst Castle and Yarmouth.

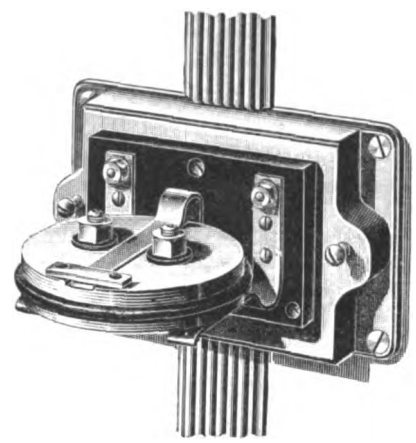
Mr. Chas. Bright said he understood Mr. Willoughby Smith had been successful in signalling to boats without communicating wires.



Mr. Granville said Mr. Willoughby Smith's experiments were quite satisfactory, and they had been discontinued partly because the Telegraph Construction and Maintenance Company had overcome the difficulties in signalling to lightships in another way, and partly owing to Mr. Smith's ill health.

Mr. Mordey said Mr. Preece had informed him that the dynamos at Deptford affected the telephones in Paris; if this were so, signalling across seas was already accomplished.

A paper was also read by Mr. F. Higgins, on "The Diathermancy of Air in Relation to the Efficiency of the Electric Lamp."



THE CARDEW EARTHING DEVICE.

We give herewith an illustration of the latest pattern of the Cardew earthing device as modified by Messrs. Drake & Gorham, Victoria Street, Westminster, and adopted by the London Electric Supply Corporation. The action of the device is to connect the secondary circuit to earth automatically whenever a dangerous difference of potential is established between the lamp circuit and earth. This result is obtained by interposing some medium which will be of infinite resistance until a dangerous difference of potential exists, when a free passage for the leakage current is provided.

View of Device as in Use.

In the device illustrated the static arrangement is adopted, as it is found to give the best results. It consists of two brass plates placed near but insulated from each other. Between these lies a thin foil of aluminium, which is retained in position by ebonite pegs, one plate being connected to earth and the other to the secondary circuit. A flat projection is formed on the upper plate over one end of the foil, so that as soon as a difference of 400 volts is established one end of the foil lifts by static attraction, and a metallic contact is made between the two plates. If there is a serious leak between the primary and secondary, and if the primary is also completely earthed elsewhere, the primary fuses in one or both of the houses in which the leaks occur are blown. These fuses will go with a current too small to cause a fire, even if one earth is through a house

View of Device with Cover Removed.

secondary—that is to say, if in one house the primary is in contact with the secondary in the transformer, the secondary will have been already earthed on one side by leakage. The plates are all made interchangeable, so that when the foil has acted it is merely necessary to slide in some fresh plates.

It has been suggested that the permanent earthing of the secondary does all that the static contact will do. Earthing the middle of the secondary circuit reduces the stress on the secondary insulation, but admits of danger from fire, as it only requires one leak to earth on the secondary to make a short circuit. With the static contact two are needed.

It is evident that the apparatus can be modified to act as a relay, and cut off both poles of the circuit, or to ring a bell and drop a danger disc, as has been arranged for the Chelsea Electric Supply Company, where continuous currents are used.

This apparatus has been adopted by the Deptford Company, the Newcastle Electric Supply Company, the Lynmouth Central Station Company, the Shanghai Electric Company, &c.

Notes.

SOUTH AFRICAN RAILWAYS.

It is stated that arrangements have been concluded by Mr. Rhodes on behalf of the British South African Company with the Cape Government for the immediate extension of the railway northwards from Kimberley, and that already considerable progress has been made. These extensions will have the effect of greatly extending British trade and influence in the district.

BRITAIN'S WHEAT SUPPLY.

As indicating the great decrease in the price of wheat during the past thirty years, it may be interesting to note that in 1851 the whole supply of wheat for a population of 27,000,000 amounted to 317lb. per head. The cost was £53,500,000. The wheat supply of 1889 was at the rate of 400lb. per head for a population of 37,000,000, and the cost was £43,700,000. The consumption of flesh foods advanced within the same period from 90lb to 115lb. per head.

STEEL SHIPBUILDING IN CHICAGO.

It is reported that steel shipbuilding on a large scale is going to be carried on upon the American lakes, and that a Cleveland iron company and a Chicago steel establishment have formed a company to build steel vessels in Chicago. The yards are to be on the east side of the Calumet river in South Chicago, and it is stated that in a few months the company will have six steamers on the stocks. There cannot be the slightest doubt but that these semi-British, American, and Colonial companies, when fully developed, will have a very great effect on our home manufactures.

A BRIDGE OVER THE BOSPHORUS.

Encouraged by the success of the bridge across the Forth, engineers are now considering the equally great scheme of a bridge across the Bosphorus, to connect Europe and Asia and their present and future railway systems. A Turkish newspaper gives some particulars of an offer by a French syndicate to build a bridge of 800 metres in length and 70 metres high between Roumeli and Anatoli Hissar. The bridge would consist of one span, which will much exceed in length the longest span of the Forth Bridge. The Anatolian railway will make the construction of such a bridge a necessary undertaking before many years are gone.

THE OPENING OF THE UPPER YANGTZE.

Some time ago we alluded to the proposal that Chung-King should be opened to foreign residence and trade, on condition that no attempt should be made by foreigners to place steamers on the Upper Yangtze for a period of ten years. It is thought, however, that the Chinese will themselves start a line of steamers, so that at the end of ten years a considerable development will have taken place. The good feeling with which these negotiations have been carried on will do much to promote friendliness, and a large and healthy trade will, no doubt, be the result.

DRAINING THE ROMAN MARSHES.

The draining of the "Agro Romano" has now reached an advanced state of completion. The main object of the works is to drain the marshes of Ostia, Isola Sacra, and Maccarese, bordering the coast about fifteen miles from Rome, and the works consist of defence banks, canals collecting high waters with a direct outlet into the sea, embankments for the area to be drained, and canals within the area. The water of the area is raised by means of machinery on the turbine system, and is discharged into the sea. The chief difficulty in carrying out these plans is the unhealthiness of the place, which sometimes renders it necessary to suspend the work for some months. Perhaps it would have been impossible to carry out the undertaking by employing ordinary labourers belonging to the Campagna and paid by the day. However, near Ravenna, there is an extensive association of labourers for this particular kind of work, and several squads are selected and are despatched to Rome every year. The men, who are of a robust constitution and sober, are not subject to a master, and have a direct control over their food, wine, and housing, as well as over their hours of work; they perform their task peacefully, and divide among themselves the price agreed upon with the contractor. Their earnings range from 3s. 4d. to 4s. per diem, and enable them to save money, which is the constant thought of the Italian workman. The amount spent by Government up to the end of 1888 in the undertaking was £139,580. The estimated cost of all the works to be executed by Government was at first fixed at £160,000, which was subsequently raised to £300,000.

LOCOMOTIVE BUILDING IN NEW SOUTH WALES.

Recently proposals were advertised by the New South Wales Railway Commissioners in the British and Colonial papers for the establishment of an engineering concern for the production of locomotives, and we understand that a contract has now been made between Sir Saul Samuel, the Agent-General for the Government of New South Wales in London, and a syndicate in this country, for the establishment in that colony of locomotive works upon an extensive scale. The company will be known as "The Australasian Locomotive Engineering Company," and Mr. Dugald Drummond, locomotive superintendent of the Caledonian Railway Company, will be the managing director.

MANUFACTURES IN HONG-KONG.

A very common impression in this country is that Hong-Kong is only a mercantile emporium or centre for the distribution of merchandise all over China and neighbouring countries. It is, however, developing into an industrial centre of considerable importance. It has now three very large sugar refineries, which have practically monopolised the trade of refined sugar in China and Japan. There are factories for ice making, rope making, and there is also a company which has a large establishment for supplying bricks and cement. There is also, we are sorry to say, a large distillery, with a very large output of rum. All these concerns are British, or at least are under British management.

PRODUCTION OF COAL IN JAPAN.

The production of coal in Japan continues to increase rapidly. The official returns for 1888 have just been published, and they show that the entire production in that year was 3,488,629,684 catties (1 catty being equal to 1·3lb. avoirdupois). Of this quantity 632,440,957 catties were produced from the Miike mines, and 149,849,861 from that of Kuratsu, both of which are under Government control. The aggregate of the production of private mines, therefore, was 2,706,638,246 catties. Compared with 1887 this was an increase of about 30 per cent. in the quantity produced. The quantity sold was in excess of that produced, the balance being made up from stocks of former years. The amount realised from abroad from the sale of coal was $17,700,000, but this does not include the value of the coal from the Government mines, the greater part of which was used in the country itself and for Government purposes. The development of the Japanese coal mines has been of the greatest service both to the ships of foreign navies and to merchant steamers.

THE KRUPP WORKS AT ESSEN.

The United States' Consul at Düsseldorf devotes a recent report to a history of the Krupp works at Essen, especially since the death of the elder Krupp, the founder, in July, 1887. It was feared by many that the great establishment would not in future enjoy the same reputation and prosperity as in the past, but, to the surprise of many, his only son assumed charge with the same spirit of energy and businesslike management that made the father so famous throughout the world, and increased business and prosperity have attended his efforts. His first act after the death of his father was to give to the city of Essen, now a place of about 70,000 inhabitants, 300,000 marks for public improvements; he then created a fund of 1,000,000 marks for the benefit of poor, sick, and disabled workmen who had devoted their lives to his and his father's service. All this rendered it an easy matter to get the best and most skilled workmen at reasonable rates of pay. Access to the establishment has been denied of late to every sightseer. The works cover about 1,000 acres. The number of men employed in all the departments three years ago was 20,000; at the present time the number reaches about 25,000 or over. Cast steel works at Essen, three coal mines near Essen and Bochum, 547 iron ore mines in Germany, several iron ore mines in Spain, four forges in other parts of Europe, a trial shooting ground 16·8 kilometres long, a trial shooting ground 7·5 kilometres long, four ocean steamers, 11 large furnaces, 1,542 smelting stoves, 439 steam boilers in actual use, 82 steam hammers, 450 steam engines, 1,622 tool-making machines, 14 large locomotive engines, and 40 small locomotive engines form part of the plant of the works. The consumption is roughly as follows:—Coal and coke, an average of 4,000 tons per day, 2,000 of which are used in the forge works and steamers; water, about 18,834 to 26,898 cubic metres per day; gas, about 13,350 to 42,700 cubic metres per day, and 400 to 1,500 tons of iron ore.

THE COAL DEPOSITS OF EUROPE.

The German *Handel's Museum* has recently published some statistics relating to the coal deposits on the Continent of Europe which are of considerable interest. The Low Countries, Belgium and Holland, Switzerland, Denmark, Germany and Bohemia, possess a coal area of nearly 60,000 square miles. Then Austria, Spain, Portugal, Italy, and Greece contain deposits estimated to cover an extent of between 30,000 and 40,000 square miles, of which only a fractional part has yet been touched. Russia has already surveyed coalfields extending over 2,200 square miles, and, in addition, the mineral is widely distributed throughout the Russian empire, in Poland, and in Siberia, in the Ural region and in the Caucasus. Careful surveys are now being made, and many of the deposits are already being worked. The production of the Central Russian collieries has been attracting a good deal of attention lately by reason of the growing output. In 1888 the collieries of the Kursk-Kharkow, Sea of Azov, and Donetz districts produced about 1,500,000 tons of coal. In 1889 they had raised the output to nearly 2,225,000 tons, an increase of nearly 50 per cent.

A PAN-AMERICAN ZOLLVEREIN.

In writing on the subject of Imperial Federation we have several times suggested that the first steps should be in the direction of trade arrangements of a more satisfactory kind than those which at present exist between this country and the Colonies. If we do not tackle the subject in real earnest we may find that in a short time we shall be driven to it by force of circumstances. For instance, it is rumoured that one of the probable consequences of the Pan-American Congress is likely to be a Pan-American Zollverein, in which there would be absolute reciprocity among all the American countries. If the proposal be adopted, it, of course, means the adoption of free trade over all the American Continents, and if that be agreed to, under such varying conditions of resources, climate, and state of industry, it is certainly possible among the various parts of the British Empire if vested and personal interests could only be set aside. It seems too much to expect a European Zollverein for many years to come, but the tendencies of the times all point in that direction. If we have international conferences to settle labour questions, it is not going very much further to suggest similar conferences for tariff and other trade purposes, as well as for purposes which are only indirectly connected with trade.

THE TRANS-SAHARA RAILWAY.

At a recent meeting of the French Académie des Sciences, M. Georges Rolland, a well-known engineer, read a paper on the subject of the above railway. He pointed out, in the first place, those regions of the Western and Central Soudan upon which French commerce might reasonably reckon, and said it was about time that France should decide the position she intended to take in the economic conquest of Africa. He was of opinion that nothing durable or really useful could be effected in the Soudan without the assistance of Algeria, while in order to take any effective action in Algeria that colony would need to be connected with the Soudan by means of a railway across the Sahara. Dwelling upon the necessity of a Trans-Sahara railway from a strategic, political, and commercial point of view, he asserted that the route from Algeria to the Soudan, although it might be the longest, might be made the most expeditious if proper influence could be exerted over the natives of the district through which it passed. He suggested that a column of two hundred French soldiers should be sent along the route for the purpose of establishing commercial stations and conciliating the natives. His conclusion was that the only practical and speedy method of opening up the Sahara was to construct a light railway of the Decauville type by way of Onarghi and Amguid.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents).")

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

1st April, 1890.

5034. Maxton, J. ..... Submerged buoyant bridges.
5038. Trott, H. ..... Valves for controlling passage of fluids.
5041. Buckley, J. ..... Mules and twiners.
5042. Ryder, G. ..... Cutting tools.
5043. Sellars, J. ..... Spindles for centrifugal machines.
5045. Haigh, Walker, & Mitchell ..... Apparatus for drilling fallers.
5047. Wrightson & Holt ..... Knitting machines.
5050. Harris, J. B. ..... Rotary engines.
5051. Barnsley, R. G. ..... Chains for transmission of power.
5060. Pearsall, H. D. ..... Valves.
5061. Rose, J. ..... Machines for cutting soles, heels, &c.
5063. Smith & Knapp ..... Steam boilers.
5064. Towne, N. P. ..... Steam boilers.
5068. Sleeman, C. W. ..... Ascertaining direction of torpedoes.
5071. Boult, A. J. ..... Piston packing (*Child*).
5073. Haensel, G. ..... Belt and fast and loose pulleys.
5074. Thompson, W. P. ..... Grain clipping machines (*Knight*)
5076. Chandler, N. ..... Single acting engines.
5077. Newton, H. E. ..... Joint for flexible shafting (*Howard*).
5078. Hunt, C. ..... Gas retorts and apparatus for charging.
5086. Lake, H. H. ..... Machines for cutting soles of boots (*Hartford*).
5088. Lake, H. H. ..... Machines for manufacture of metal screws, pins, &c. (*Worsley*).
5091. Pitt, S. ..... Machine for hulling grain (*The Engelber Huller Company*).
5092. Jones, E. R. S. ..... Ramps.
5093. Pœtsch, F. H. ..... Sinking shafts.

2nd April, 1890.

5100. Morfittt, A. ..... Platen printing machines.
5103. Reade & McKibbin ..... Flyers of spinning machines.
5115. Cripps, F. S. ..... Channel-Tee iron.
5117. Wilson & Welsh ..... Boiler furnaces.
5118. Besson, H. ..... Machinery for bevelling glass.
5120. Young, A. ..... Railway chairs.
5123. Birchenough & Wood ..... Looms.
5126. Cox & Gordon ..... Typewriters.
5127. Banks, K. ..... Apparatus for shaping nuts, &c.
5129. Plumbridge, Sen., Plumbridge, Jun., & Jackson Band saw guides.
5130. Lapworth & Hayes ..... Water tube steam boilers.
5133. Matthias, E. A. ..... Apparatus applicable for cutting coal (*Plowman*).
5134. Thompson, W. P. ..... Grain elevators (*Rostand*).
5142. Theissen, E. ..... Condensing steam.
5152. Garden, W. ..... Refrigerating machines.
5153. Garden, W. ..... Stuffing boxes.
5154. Thomson, J. ..... Platen printing presses.

3rd April, 1890.

5163. Woodhouse, S. J. ..... Charging retorts.
5165. Knight & Higgins ..... Steam generators.
5166. Kollén, A. B. J. ..... Machinery for finishing horseshoe nails.
5173. Winchester, J. ..... Tramcars.
5175. Shanks, Tardew, & Andrews ..... Brick moulds.
5179. Sample & Ward ..... Boat detaching gear.
5180. Witt, S., Jun. ..... Brick making machine.
5183. Sykes, J. ..... Preventing running back of tramcars.
5188. Dixon & Dixon ..... Brick machines.
5192. Melhuish, A. G. ..... Gas motors.
5194. Waller, G. ..... Cooling and conveying coke.
5198. Rauhe, C. ..... Drilling machine for cartridge shells.
5211. Lye, H. J. ..... Sifting machines.
5213. Collins, J. ..... Brake for railways.
5220. Comerford, J. ..... Apparatus for drying grain.
5222. Boult, A. J. ..... Shells for high explosives (*Justin*).
5223. Cooper, Roe, Cooper, & Taylor ..... Rotary knitting machines.

5th April, 1890.

5231. Shardlow, A. ..... Split pulleys.
5232. Milnes & Birks ..... Shaping spherical projectiles.
5238. Hersey, J. ..... Pipe wrenches.
5241. Rowley & Rowley ..... Apparatus for mixing sand.
5244. Guest & Brookes ..... Reeling machines.
5247. Burman & Burman ..... Shearing and clipping machines.
5248. Priestley, G. F. ..... Valve for gas engines.
5254. Young, Young, & Wright Hydraulic lifting jacks.
5255. Cooke, W. ..... Steam generators.
5256. Mills, B. J. B. ..... Jacquard apparatus (*Ronze*).
5265. Koch, E. ..... Differential friction wheels.
5267. Chapman, A. ..... Evaporating apparatus.
5273. Otto, N. A. ..... Gas engines.
5275. Otto, N. A. ..... Petroleum engines.
5276. Cameron, D. ..... Anti-friction bearings (*Millhauser*).
5277. Kirkaldy, J. ..... Reducing valves.
5278. Kirkaldy, J. ..... Steam boilers.
5281. Stevenson & Milburn Rotary motors.
5284. Nilsen, A. B. E. ..... Manufacture of casks.

ELECTRICITY.

1st April, 1890.

5048. De Méritens, A. ..... Sterilising liquids by magnetism.
5049. De Méritens, A. ..... Sterilising liquids by electricity.
5054. Kellner, C. ..... Bleaching fibrous material by electricity.
5062. Van Depoele, C. J. ..... Electric railways.
5087. Lake, H. H. ..... Electric cables (*Barrett*).

2nd April, 1890.

5135. Belfield, R. ..... Cores for transformers (*Westinghouse*).

3rd April, 1890.

5219. Andersen, F. V. ..... Electric arc lamps.
5228. Thompson, W. P. ..... Galvanic elements (*Hoppe & Hoppe*).

5th April, 1890.

5235. Sayers & Sayers ..... Electric generators and motors.
5274. Abel, C. D. ..... Telephonic and telegraphic transmission (*Société Générale des Téléphones (Réseaux Téléphoniques et Constructions Électriques) & Picou*).

CHEMISTRY.

1st April, 1890.

5058. Delplace & Delplace ... Sulphuric acid.
5072. Mond, L. ..... Treating phosphatic minerals.

2nd April, 1890.

5140. Thoms, W. A. ..... Coating metallic surfaces with metals.
5155. The Clayton Aniline Co., Ld., & Hall ..... Colouring matters.

3rd April, 1890.

5199. Electric Construction Corporation, Ld., Parker, & Robinson Copper nickel matte.
5205. Wilton, T. ..... Sulphate of ammonia.
5209. Lake, H. H. ..... Explosives (*Maxim*).

5th April, 1890.

5239. Blum, J. ..... Water gas.
5243. Fourness, H. ..... Carburetting water gas.
5287. De Graef, L. J. ..... Phosphates.

MISCELLANEOUS.

1st April, 1890.

5026. Russell, J. ..... Sound signalling at sea.
5031. Drayton & Wilkins ... Gradient indicator.
5033. Philburn, A. ..... Flyers used in spinning.
5040. Taylor, J. ..... Extinguishing fires.
5053. Kellner, C. ..... Softening paper pulp.

2nd April, 1890.

5106. Tuquet, Boudard, & Crawley ..... Fasteners for driving belts.
5128. Kellner, C. ..... Manufacture of paper.

3rd April, 1890.

5177. Morice, J. L. ..... Distributing oil on water.
5185. Jackson, I. ..... Joining driving belts.
5187. Dennis & Naylor ..... Taps and cocks.
5196. Walliker, J. G. ..... Manufacturing barrels from paper pulp.
5200. Vickers & Vickers ..... Distributing oil.
5226. Thompson, W. P. ..... Lanolin as a lubricant (*Krause*).

5th April, 1890.

5279. Smith, E. H. ..... Pantographs.
5285. Kellner, C. ..... Bleaching vegetable fibres.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

3997. Blackwell.
5430. Lautz.
5558. Downie & Snowdon.

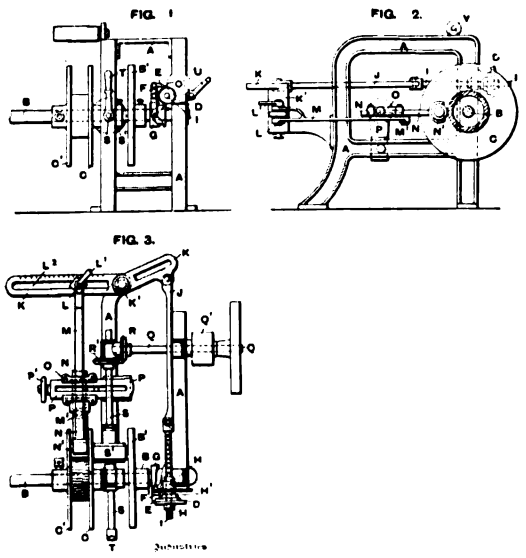
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

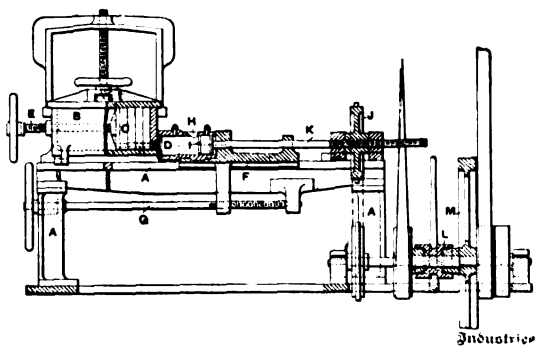
STEAM BOILERS.—*H. Tomkin & T. Sudron & Co., Stockton-on-Tees.*—A new arrangement of the cross-tubes and combustion chamber in vertical boilers constitutes this invention. The cross-tubes extend the full distance across the boiler to the shell on either side, to which they are riveted or otherwise secured. The boiler shell is thus reduced in strength only by the loss of sectional area of the tubes, and the loss may be compensated by plates extending round the holes cut. The cross-tubes communicate at one end with the combustion chamber and at the other end with the smoke box, the combustion chambers and smoke-box being situated on and secured to the outside of the boiler shell, which consequently is not cut away for their accommodation. The water space is also not encroached upon by the combustion chamber and smoke-box. The combustion chamber communicates with the top part of the fire-box by short tubes of large diameter passing through the fire-box lining and outer shell. The cross-tubes are arranged in series one above another, and the combustion chamber and smoke-box divided off by horizontal partition into two or more compartments. The products of combustion thus pass from the top of the fire-box into the lower part of the combustion chamber, from there through the cross-tubes to the lower part of the smoke-box, and then back again from one to the other through the cross-tubes until it finally escapes to the uptake. Claims: (1) In vertical steam boilers arranging the cross-tubes to communicate directly between the combustion chamber and smoke-box by extending them across the full width of the boiler to be connected with or without compensating plates directly to the boiler shell; (2) in vertical boilers arranging the cross-tubes in tiers or sets communicating with the combustion chamber and smoke-box and with each other for diverting or reversing the currents of hot gases, which tubes are connected with or without compensating plates directly to the boiler shell.—No. 5627. April 2nd, 1889. 8*d.*

ADJUSTABLE ECCENTRICS OR CRANK PINS.—*G. H. Townsend, Queenstown, Ireland.*—An eccentric constructed according to this invention may be readily adjusted, and, if desired, whilst in motion. Fig. 1 is a front view of the eccentric, and Fig. 2 a longitudinal central section upon a side view. The working eccentric C is combined with an inner adjustable eccentric B which is keyed to the shaft A. Upon the shaft A is fitted a sleeve D having fast to one end a pinion E. The pinion E gears with a second pinion E^1 upon the boss of an arm G, which is secured at its end to a stud L in the outer eccentric C. In the position shown in full lines in Fig. 1 the two eccentrics neutralise



one another, and the stroke is therefore *nil*; if, however, the outer eccentric be turned, as shown by the dotted lines, about the inner eccentric, it acquires a throw proportional to the amount turned. To turn the outer about the inner eccentric, means as illustrated in Fig. 2 are used. The sleeve D has a helical groove, and the shaft A a straight groove; in the grooves works a pin secured to the flange collar I, and being with it moved backwards and forwards by the screw S. With these slots and pin the relative position of the sleeve to the shaft may be changed, and so the pinion E revolved, moving the arm G and causing the outer eccentric to assume any desired position upon the inner eccentric. Four claims are made.—No. 6818. April 23rd, 1889. 8*d.*

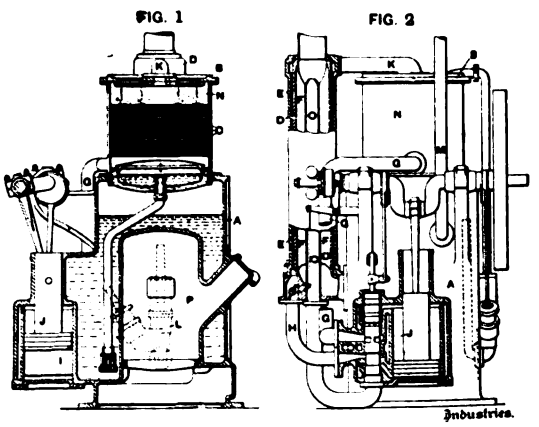
PICKING-STICK TAPPETS OF LOOMS.—*B. Berry & D. B. Briggs, Bradford.*—An improvement is made in the male clutch tappet or shuttle picking-stick tappet, to facilitate the lubrication of the steel runner or bowl attached to it. The tappet is cast hollow to form a chamber for the reception of the lubricant. A small aperture is made in the lower part of the chamber and immediately over the bowl to permit the lubricant to drop on to the bowl and so lubricate it. A small air valve is fitted in the upper part of the chamber for the admission of air. Claims: (1) A tappet for weaving looms provided with an oil or lubricating hollow chamber having a duct leading to the anti-friction roller or bowl carried by the said tappet adapted to supply the said steel roller or bowl with oil or lubricant; (2) the combination with a tappet provided with an oil or lubricating chamber and an educt of air valve arranged for the passage of air as described.—No. 7167. April 30th, 1889. 6*d.*



STEAM GENERATORS.—*J. W. Boulton, Ashton-under-Lyne.*—To the upper end of the common cross-tubes fitted to the flues of boilers, the inventor fixes an upright tube of sufficient length to conduct the hot water in the tube to the surface of the water in the boiler. In the case of horizontal tubes in vertical boilers, extensions are fitted to both ends, one extending downwards and the other upwards, the water being fed into the tube by the downward one and passing to the surface of the water in the boiler by the upward one. To prevent priming, the end of the upper tube is closed, and one or more openings made in the side, in order that the water may be cast downwards and not into the steam space. By this construction of cross-tubes the heated water contained in them is allowed to rise to the surface without coming into contact with the colder body of water which is between the top of the flue and the working level, and therefore causes a better circulation in the boiler. Claim: As means for obtaining an improved circulation of water in steam boilers by means of extending the cross or heating tubes at one end or both to, or near to, the surface of the working level of water over the flue or flues, and by extending the lower ends to, or nearly to, the bottom of the boiler shell.—No. 5957. April 8th, 1889. 6*d.*

SECTIONAL WARPING MACHINES.—*E. Rothwell & W. A. Rothwell, Bolton.*—Most of the usual complicated mechanism is dispensed with, and a positive equal traverse is given to the "presser" for each revolution of the shaft on which the section blocks are mounted. To effect the above, the inventors make use of the usual shaft B (see Figs. 1, 2, and 3), and cause it to give motion to a ratchet wheel D. The wheel D is mounted

upon the framing, and its boss threaded to receive the screwed rod I. The screwed rod I is connected to the lever K, which is pivoted to the framing at K^1. The presser holder N is connected to the rod M, whose other end is secured to a block L adjustable in the slot L^2. The presser holder rod M is supported in slideways O, which are adjustable by means of the hand wheel P^1. Previous to winding a trial section, the block L is slackened so as to determine the position of the block, and after the trial section is formed it is tightened. The machine can then be started, and the presser N^1 will be moved automatically as the section increases in size. Claims: (1) In a sectional warping machine the combination with a pivoted slotted regulating lever actuated by a ratchet motion or equivalent mechanism from the section shaft, of a rod pivoted at one end to a stud fitted in the slot of the regulating lever and at the other end connected to the presser holder which is guided in adjustable slideways as described; (2) the combined arrangement of parts as described.—No. 6639. April 18th, 1889. 8*d.*



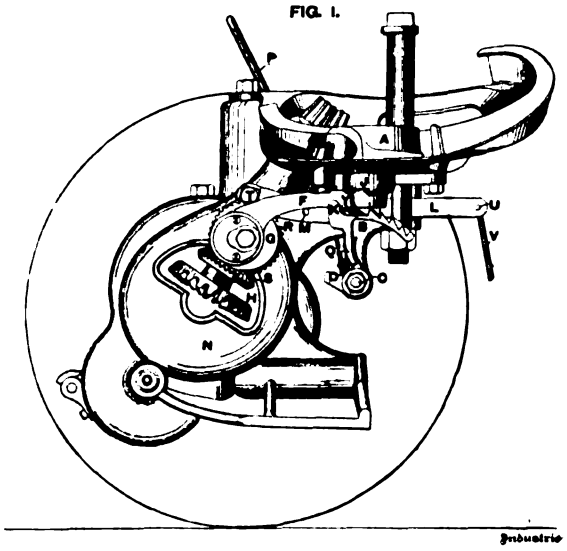
CASTING UNDER PRESSURE.—*J. Mackintire, London.*—The apparatus here described is particularly adapted for the manufacture of elbow-pieces, T pieces, and similar articles in steel. The inventor overcomes one of the difficulties of casting in steel under pressure—viz., the metal losing its fluidity before the mould is filled—by keeping the molten metal in motion until the moulds are filled. A is a frame or table, on one end of which is fixed a mould box B; C are the moulds, which are forced and held together by a screw E and follower; D is the metal cylinder, which is placed on a sliding bed F, capable of being moved horizontally by the screw G. The metal cylinder D is formed with a charging mouth H, of considerable width and depth, which will allow the molten metal to run easily and rapidly into the cylinder, and also permit of the egress of all air before the piston closes up the charging mouth as it moves forward. I is a piston working in the cylinder D, and capable of being moved in either direction

by the pulley J and screw K. The pulley J is driven by the gear shown above, the gear having a controlling clutch arrangement L. The apparatus works as follows: The molten metal is poured quickly into the cylinder D, and before its movement is arrested the clutch H is put into gear and the piston I is driven rapidly forward, forcing the molten metal into the moulds. When the moulds are full the momentum of the fly wheel M gives the metal a final squeeze. Claims: (1) In machinery for casting in metal under pressure applying the momentum of a fly wheel to actuate the piston of a cylinder into which the molten metal is run previous to being forced into the moulds; (2) in machinery for casting articles of metal under pressure the combination with the piston rod of the metal cylinder of means as described for communicating motion to the piston rod in either direction; (3) refers to a form of press for making cores; (4) making pipe fittings in cast metal with rounded corners or angles, as described; (5) in machinery for casting articles in metal under pressure the use of a cylindrical molten metal receiver having a wide and deep charging mouth, for the purpose set forth.—No.5651. April 2nd, 1889. 8*d.*

COLLIERY TUB WHEELS.—*W. F. Butler, Wrexham, Denbigh.*—The application of this invention is for the purpose of improving the lubrication of colliery tub wheels, especially such as travel fastly around tracks of small radii. The wheel has a rim constructed in the ordinary way, but it is provided with an annular box or chamber around its hub. This box is cast in one piece with the hub and rest of the wheel; it is opened upon the outer side of the wheel, but covered by a loose cap which encloses at the same time the end of the axle and the hub. This annular box is used as a lubricating box, an aperture being made in the cover for the purpose of filling it with lubricant. Claims: (1) A colliery tub or other wheel, as described—that is to say, a wheel having a chamber round the hub adapted to serve as a lubricant chamber to the axle upon which the wheel works; (2) a colliery tub or other wheel comprising an outer rim, a hub, and an intermediate ring or web, and a cap or cover, the chamber formed between said hub and said ring or web being constructed and adapted to be used as a lubricant box, and whereby a casing or covering is provided and the axle fittings protected; (3) a colliery tub wheel constructed as illustrated in the specification.—No. 7683. May 8th, 1889. 8*d.*

MOTORS.—*W. Schmidt, Halberstadt, Germany.*—In motors for light work driven by steam and air mixed, a great improvement is effected by the use of two boilers separated and working under different pressures. The application of this idea is shown in Figs. 1 and 2 of the accompanying drawings. Fig. 1 is a vertical section through the motor; Fig. 2 is an elevation with the steam and air cylinder in section, as also a part of the superheater. A is the low-pressure part of the boiler where the water is heated by the fire in the fire-box P. The hot water is then pumped by means of the pump L into the upper part of the boiler or evaporating boiler N; it then flows through the cover B on to and through the sieve C, where it becomes separated into very small particles. These falling particles of water are met by the current of air driven into the evaporating boiler from the air chamber J of the cylinder through the pipe G. Some of the hot water will now rapidly evaporate, whilst the remainder cools. The cool water then sinks to the bottom of the boiler, where, by means of an outlet pipe or, as shown in the drawing, the arrangement with a float, it is taken again into the low-pressure boiler A. The mixture of air and steam, produced in the high-pressure boiler, is now passed through the superheater D E, where it is superheated or dried, and then enters the cylinder. The superheater consists of the two pipes D and E, between which the steam and air mixture passes. The inside pipe D has the ribs F in order to catch off more heat from the escaping fire-gases. Inside the pipe D the steam outlet

pipe O is fixed, so that the exhaust mixture of steam and air is used for increasing the fire draught. Claims: (1) The method of first heating the water in a low-pressure boiler, pumping the same into an evaporating boiler from above, where it is met by air compressed into the boiler from below, thus causing rapid evaporation, then superheating the mixture and using the same as motive power; (2) the combination of a boiler A, an evaporating boiler N, a steam and air cylinder, a pump L and superheater; (3) the combination with boiler A of the evaporating boiler N, having cover B, sieves C, hot water inlet, air inlet G, and connected with the superheater by pipe K, and with the water of the low-pressure boiler by float arrangement; (4) in combination with boilers A and N and pump L, the superheater, consisting of pipe D, having ribs F, outer pipe E, and exhaust pipe O, and having connections with boiler N and cylinder as described.—No. 4237. March 11th, 1889. 6*d.*



STEEL ARMOUR PLATES.—*J. Y. Johnson, London.* (*C. Pieper, Berlin.*)—The plates are composed of a number of thicknesses or layers of metal of different hardness and tenacity. The layers of metal are so arranged that taking a plane in the interior of the plate the hardest layer is inwards, being enclosed outwardly on both sides by a softer layer, or the hardest layer—hard steel, for instance—is covered on both sides with a layer of less hard steel, this less hard steel being again covered by a still softer layer of metal, such as soft tough cast iron. The several layers or thicknesses are welded together. In the production of the compound plates the metals employed in the formation of the several layers or thicknesses are cast either simultaneously or in immediate succession in a mould provided with as many compartments as there are different thicknesses of metal. For example, a mould employed in the manufacture of a plate with a hard internal core placed between two softer layers is made with three compartments. This mould consists of a shell, in which is placed a box made of sheet iron or steel, the sides being made so thin that they are completely or almost completely fused between the hard and soft metal run into the box. By these means the several layers are firmly united. Two claims are made.—No. 10472. June 27th, 1889. 8*d.*

Digitized by Google

SHAPING MACHINES.—*T. M. Bear & J. Paxman, Colchester.*—This improvement is to enable the work beds of shaping machines to be moved in a horizontal, vertical, or circular direction. To the front of the vertical face of a shaping machine bed is attached by bolts, the heads of which engage in the usual horizontal slots, an apron capable of a horizontal movement when the bolts are loosened. This apron has vertical V-shaped slides, on which works a correspondingly grooved plate carrying the usual circular work table. The plate is moved vertically (and, consequently, the table) by means of a worm operating a worm wheel upon a vertical screwed spindle, which travels through a nut connected to or forming part of the plate or work table. To give a circular movement to the work table, it is affixed to the plate so as to be capable of revolution, and its inside face is provided with a worm wheel, which is operated by a worm, so that the table can be rotated by hand to bring any face of the work under the tool. Three claims are made.—No. 7697. May 8th, 1889. 8*d.*

REAPING MACHINES.—*P. Pierce, Wrexford, Ireland.*—This invention consists in improvements in the mechanism for controlling the action of the rakes of self-delivery reaping machines whereby the rollers of the rakes are caused to run either on the outer surface of the "switch" or behind it as desired. The invention will be understood by reference to Fig. 1, which is a side elevation of the framing of a reaper provided with the improved construction of controlling device, Figs. 2 and 3 are side

FIG. 1.

and end elevations of the device, and Figs. 4 and 5 are plans of same. The gearing is enclosed in a box N. A is the ordinary switch, shown in Fig. 1, closed or in its normal position. The object of the controlling device is to automatically open the switch A and permit the rake roller to pass behind it, allowing the rake to sweep the platform. In connection with the switch A is employed a toothed sector B which is capable of oscillating to an adjustable extent upon the pin C. The sector has two rows of teeth, an inner row which is acted upon by a pawl F, and an outer row in which engages a drop catch T mounted in a guide on the thimble J. The thimble J is secured to the same pivot as the switch A, and the latter is thus kept in its closed position by the coiled spring W upon the thimble J. By suitable bevel gear wheels H, S, and G, and an eccentric, the pawl F is given a to and fro motion, which causes the sector B to advance tooth by tooth, whilst the catch I retains it. When the sector B is sufficiently advanced a projecting part K strikes a second projection X upon the thimble. The thimble, and consequently the switch A, are partially revolved, opening the latter and allowing the rake to sweep the platform. At the time the thimble is thus partially revolved the drop catch I is removed from the teeth of the sector, and the catch F in making its backward

FIG. 4

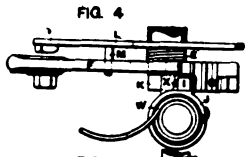


FIG. 5

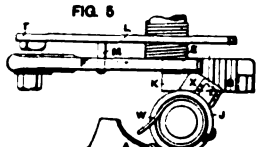

FIG. 2

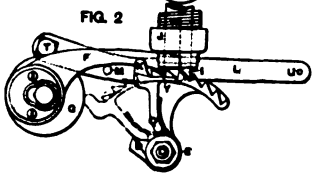

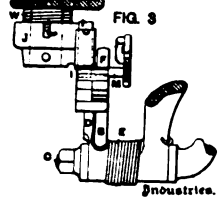

FIG. 3

movement is lifted by the pin M also out of the teeth, so that the sector, being freed of its catches, returns to its starting point. The number of teeth the sector B is advanced before opening the switch A may be regulated by adjusting the extent of its movement upon the pivot C. The sector B may be returned to its starting position at any point by the attendant lifting the end U of the lever L. Claims: (1) In a rake controlling mechanism the dropper latch I working in a guide thimble J or its equivalent, and acting in the manner set forth; (2) in a rake controlling mechanism the dropper latch I working in a guide thimble J or its equivalent in combination with the toothed sector B; (3) in a rake controlling mechanism the dropper latch I working in a guide thimble J or its equivalent in combination with the pawl lever F and sector B as set forth; (4) the construction of automatic rake controlling mechanism for reaping machines as shown and described.—No. 2968. February 19th, 1889. 8*d.*

STRETCHING LACE.—*L. Lindley, Nottingham.*—Improvements are here made in the ordinary tentering frame, for enabling the fabric to be stretched longitudinally as well as laterally. The regular extension of the sections carrying the tentering hooks, pins, or clamps is caused by elastically connecting the sections together in the following way: At one end of each section is an extension in the shape of a long stud, which enters the end and passes into a space of the adjoining section. Around that part of the stud which projects into the space of the adjoining section is coiled a spring. The spring is compressed against the end of the space by a washer and nut screwed upon the end of the stud, thus tending to keep the ends of the two sections together. In using tentering apparatus constructed as above described, the fabric is placed upon the tentering hooks when the sections are in a closed position; the ends of the fabric are attached to cross bars, one of which is fixed stationary, and the other to a travelling longitudinal bar. The sections of tentering hooks adjoining the stationary cross bar are fixed, whilst those at the farther end of the fabric are attached to the travelling cross bar. By giving motion to the movable cross bar the fabric will be equally stretched throughout its entire length. Claims: (1) In machinery or apparatus of the character herein referred to, employed in stretching, dressing, and finishing lace and other like fabrics, the method of elastically connecting the sections or links carrying the tentering hooks, pins, or clamps for the purpose described; (2) in machinery or apparatus of the character herein referred to, employed in stretching, dressing, and finishing lace and other like fabrics, the employment of elastically connected sections or links carrying tentering hooks, pins, or clamps, in which an extension from one end of each section or link extends beyond the adjacent end of an adjoining section or link and has a spring interposed between such parts as and for the purpose described.—No. 5702. April 3rd, 1889. 8*d.*

ROTARY ENGINES.—*L. Bohnen & M. Kleber, Berlin.*—The illustrations given of this rotary engine show—Fig. 1, a plan; Fig. 2, a section upon a side elevation; Fig. 3, a section upon an end view; Fig. 4, a side view of the piston and parts in connection with it; and Figs. 5 and 6, details. In a bored cylindrical casing A moves the rotary body or piston B. The piston is cut out, or has a semi-circular groove, in which are provided two helical ribs D E. These ribs bear closely against the inner wall of the cylinder, and a semi-circular shoulder L fixed to the cylinder. A disc I, whose periphery exactly fits the groove in the piston, is free to rotate upon an axle O, placed at right angles to the piston rod. The disc I separates the steam inlet and outlet ports, and has slots, which allow the ribs of the piston to pass as the latter is revolved. The piston is revolved by

FIG. 2

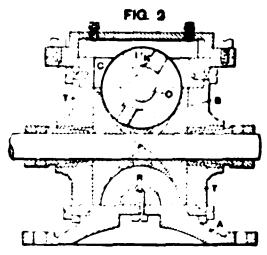

FIG. 3

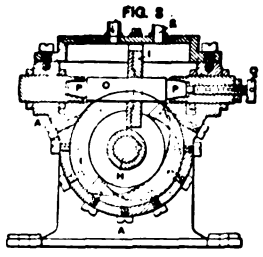

FIG. 1

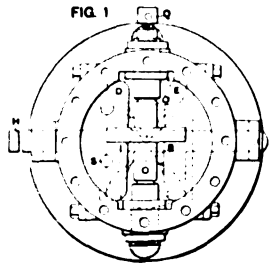

FIG. 4

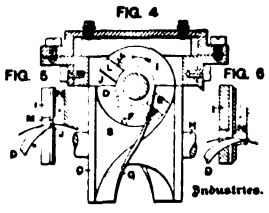

FIG. 5

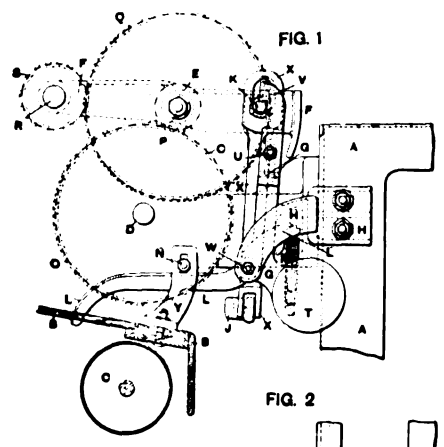
FIG. 6

admitting live steam between the disc I and the ribs D E. The inlet port for the steam is directly behind the disc I, so that the ends of the ribs are immediately acted upon as they pass through the slots in the disc, and the piston is ratated. When the ends of the ribs have passed the disc, the dead steam is exhausted through the tube S. Claims: (1) A rotary motor, working by steam or other elastic fluid, consisting of a casing A, wherein a rotary piston B and a disc I are placed at an angle to one another, and work in the manner set forth; (2) in a motor constructed as hereinabove specified a rotary piston, grooved or recessed, and provided with the ribs as described; (3) in a motor such as hereinabove specified, the disc I having slots for the passage of the ribs B and fitted with the movable slide L.—No. 3782. March 4th, 1889. 6*d.*

CLEANSING FILTERS.—*H. W. Berkefeld, Celle, Germany.*—The cleansing device is attached to filters whose body is of a tubular form closed at the bottom. The device consists of a series of brushes arranged to be revolved in contact with the outside of the body. The body of the filter is enclosed in a vertical cylindrical chamber, which has openings in the top part for the inlet and outlet of the water filtered, and at the bottom a third opening for flushing and cleansing purposes. A spindle enters at the bottom, and projects up into the filter, supporting the frame carrying the brushes which surround the body of the filter. This spindle is screwed to the filter, and carries the valve closing the flushing outlet; a hand wheel is also secured to it outside the filter. The water filtered enters the annular space between the body and case of filter, and, after percolating the body, passes out at an opening in the top of the filter. When cleansing the filter, the hand wheel of the spindle is turned, thus screwing up the spindle and opening the flushing valve, and revolving the brushes in a helical direction around the body of filter. The dirt is thus removed from the body and carried away by the water passing out through the flushing valve. Claims: (1) A cleansing and scouring device for filters with cylindrical filtering bodies, characterised by a spindle carrying the flushing valve, the brushes or scouring device, whereby the outside of the filtering body is cleansed and the filter casing flushed and washed out as described; (2) in a cleansing and scouring device for filters or tubular filtering bodies, the cleansing of such bodies by means of a brush or similar scouring device, which, by the operation of a spindle, is simultaneously moved along and around the filtering body as described.—No. 7609. May 7th, 1889. 8*d.*

SELF-ACTING MULES.—*J. Clegg, Oldham.*—These improvements in self-acting mules are to overcome the tendency of the pinion on the drag lever to jump out of gear with the spur wheel on the back shaft just at the moment when the carriage starts on its outward run. Illustrations are given of a mule with the invention applied, Fig. 1 being a side elevation and Fig. 2 a plan. Of the usual parts of the mule, A is part of the headstock, B the carriage, C the tin roller, D the backshaft, E the drag pinion, F the drag lever. To prevent pinion E jumping out of gear with the wheel O when the carriage B starts upon its outward run the inventor employs an elbow lever G pivoted to a bracket at W. The short arm of this lever is weighted at T, and its long arm provided with an adjustable catch V, which engages at the proper time with the square stud K and holds the drag lever F down. A second lever L is pivoted at W, and its short arm connected by the coiled spring M to the weighted end of the lever G. The long arm of the lever L is depressed by a bowl N upon the inward motion of the carriage B. The appliance works as follows:—Before the carriage B commences its outward run the link X actuated by the cam fork lever J in the ordinary way lowers the drag lever F and brings the pinion E into gear with the wheel O. This movement lowers the stud K, and it is immediately latched

FIG. 1



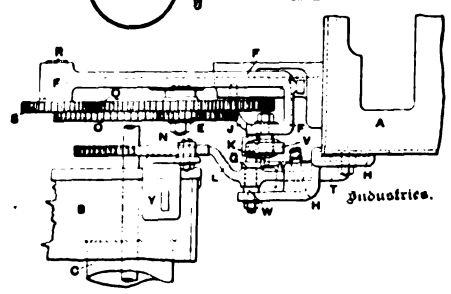


FIG. 2

by the elbow-lever G by reason of the tension put into the coiled spring M by the bowl N depressing the lever L. After the carriage has run out a few inches the bowl N leaves the lever L and releases the spring M, allowing the weighted arm T to remove the catch from the stud K. Claims: (1) Locking the drag lever at the moment when the mule carriage starts on its outward run by means of a combination of mechanism such as that herein described which consists of a square ended stud or equivalent projection on the drag lever, a weighted elbow lever fulcrumed on a stud, a second lever also fulcrumed on said stud, and connected at one end by a coiled spring to the weighted arm of the elbow lever and at the other end adapted to be acted on by a bowl on the mule carriage; (2) a latch lever for locking the drag lever of a self-acting mule, said latch lever being operated from the mule carriage by the connections described.—No. 20325. December 18th, 1889. 8*d.*

ELECTRICITY.

ELECTRICAL TRANSFORMERS.—*W. C. Johnson & S. E. Phillips, London.*—The object of this invention is to reduce the number of breaks in the magnetic circuit of an electrical transformer, to reduce its resistance. The core is constructed of thin soft iron plates separated by paper or coated with a varnish containing French chalk. The plates are made of different lengths, and their ends beveled to form angular or V-shaped ends to the core. After winding upon the core so formed the primary and secondary coils, the core is surrounded by a loop or shell built up similarly to the core of thin plates. Two V-shaped notches are cut in this laminated loop to receive the correspondingly shaped ends of the core. The whole thus represents the shape of a chain link with a bar constituting the core passing across its middle, the laminations being at right angles to the plane of the link. According to another construction two separate closed loops or links are employed, placed side by side so that a central core is formed by the two contiguous sides of the loops. In like manner a single closed loop may be employed, cut through at one point to allow of the coils being wound on one side of the loop. Or the loop may be left entire and have circular or other shaped holes cut in opposite sides to admit the ends of a laminated core, a close contact between the ends of the core and the loop being ensured by the use of wedges to expand the core. Five claims are made.—No. 7856. May 10th, 1889. 8*d.*

ELECTRIC SWITCHES.—*A. G. Goldston, Middlesbrough.*—An oscillating switch lever is pivoted at its centre to suitable brackets upon the base plate. A handle is attached at right angles to and at the centre of the lever, and constitutes the means for oscillating it. The ends of the lever when pressed down pass between pairs

Digitized by Google

of spring contacts attached to the switch base in such a manner that as one end of the switch lever is lowered it makes and the other end breaks its circuit. One pair of contacts has attached to it the terminals of the lamp, and the other pair are for short-circuiting the circuit, whilst the main line circuit is attached to the lever supporting brackets Claims: (1) In an electrical switch the combination of a switch lever provided with two conducting pieces insulated from each other, and adapted to be permanently connected to the main circuit, and two pairs of contacts, one of which pairs is designed to be connected with the terminals of the circuit to be introduced, while the other pair is in electrical connection; (2) an electrical switch adapted to cause the main line current to pass through an "introduced" circuit or through a short circuit, the arrangement being such that when the current is passing through the short circuit the terminals of the "introduced" circuit will be out of electrical contact with the switch or with themselves; (3) the manufacture and use of the improved electrical switch as described.—No. 6384. April 13th, 1889. 8*d*.

DYNAMOS.—*W. Thompson, Dresden.*—This dynamo is designed without commutator or brushes. The accompanying illustrations show Fig. 1 a front elevation, and Fig. 2 a section upon a side elevation of a dynamo constructed according to this invention. The armature consists of four electromagnets, H, H^1, H^2, and H^3, which are wound in such a manner that two opposite magnets are negative and two positive poles. The ends of the wires are brought through the hollow shaft to the metallic plugs D D^1, which are insulated from the shaft by the bushes E E^1. In the plugs D D^1 are inserted cones F F^1, which are mounted upon springs G G^1, and so form a continuous contact with the plugs. On the shaft are secured the pulley C and a gear wheel I, which gears with the wheel J, free to revolve upon its stud L. To the wheel J is pivoted an arm T, by whose means the field magnets K K^1

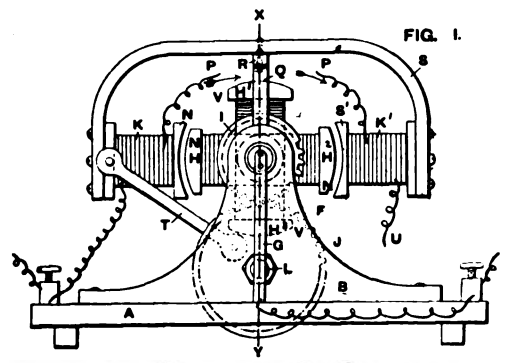

FIG. 1.

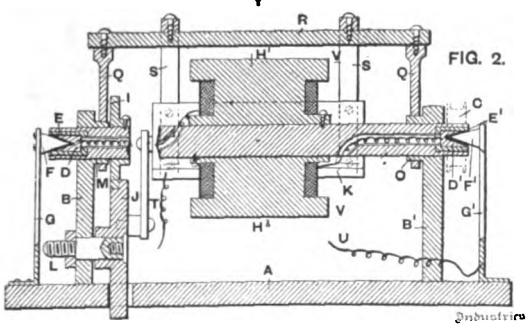

FIG. 2.

are made to oscillate. The magnets K K^1 are supported by soft iron bars S, cross-bar R, and standards Q. The connections are made as follow:—From field K, wire I^1, field K^1, through wire U, to spring G^1, cone F^1, plug D^1, through the armature to plug D, cone F, spring G, to outer circuit and back to field K. The current is generated by the quick approaching and receding of the armature's poles to and from the fields during the rotation of the armature. Claims: (1) The improved dynamo, combining therein a revolving armature, consisting of four or more electromagnets and two or more oscillating field magnets; (2) the improved dynamo, combining therein an armature revolving on a shaft with insulated metallic plugs, corresponding cones on metallic springs oscillating field magnets; (3) the improved dynamo, combining therein an armature revolving on a shaft carrying a gear wheel, which transmits its movement to a second gear wheel, connected by an arm with the field magnets, and by which motion the fields are made to oscillate.—No. 950. January 18th, 1889. 6*d*.

ELECTRICALLY-DRIVEN FANS.—*H. G. Watel, London.*—The fans are driven by electricity, applied in such a manner that there is no strain of bands or other connections for transmitting power, nor any torsional stress on the shaft. For this purpose the rim of the fan is converted into the armature of an electro-dynamic machine, or the ring armature of such a machine is applied to the periphery of the fan, and the fixed framing within or against which the fan works converted into field electromagnets or such field magnets applied to the framing. The coils of the armature or those of the field magnets are connected to a suitable commutator on the axis of the fan, and thus when the machine is put in circuit with a suitable source of electricity the fan is caused to revolved by the magnetic action applied at its periphery. Instead of employing an armature of complete ring form it may consist of segments of a ring or it may be of spoke form, the magnetic force acting at the outer extremities of the spokes which correspond with the periphery of the fan. Permanent magnets may take the place of the electromagnets which in the working of the machine undergo no change of polarity. Claims: (1) The hereindescribed method of driving a fan by providing the fixed framing and the revolving fan with suitable coils and commutator so that when supplied with electricity they operate together as an electro-dynamic machine; (2) the combination of a stationary coiled ring frame with a fan having its spokes or rim coiled and a suitable commutator, operating as an electro-dynamic machine to drive the fan, substantially as described.—No. 6675. April 18th, 1889. 6*d*.

CHEMISTRY.

COLLECTING CARBONIC ACID.—*C. R. C. Tichborne, A. F. Darley, & M. F. Purcell, Dublin.*—This specification describes a method of collecting and purifying the carbonic acid and other gases given off by liquors in the process of brewing. The gases evolved are carried by pipes, conduits, or other conducting apparatus through a refrigerating medium, the gases being either at the normal pressure of the atmosphere or under such pressure as may be deemed most suitable for procuring the deposition of the bye-products contained in the gases evolved. The gases when freed from such bye-products are compressed by the most suitable means, to such an extent as is required for the various purposes the gases may be employed for in the arts and manufactures. Five claims are made.—No. 3707. March 2nd, 1889. 8*d*.

MANUFACTURE OF WHITE LEAD.—*P. Bronner, Stuttgart, Germany.*—The method of manufacturing white lead which forms the subject ot this invention is based upon the discovery that lead sulphate can be very readily decomposed by heating it together with a certain quantity of soda lye, if this quantity be determined, so that the product will be, not hydrated oxide of lead, but a basic salt. If this quantity be such that the compound $2PbSO_4,Pb(HO)_2$ is produced, the latter can immediately be transformed into excellent white lead, $2PbCO_3,Pb(HO)_2$, by heating the same together with a suitable quantity of sodium carbonate. The bye-product obtained is Glauber's salt. The lead sulphate, which has been freshly precipitated and purified by washing, is heated together with two molecules of caustic soda for three molecules of the sulphate, the basic salt $2PbSO_4,Pb(HO)_2$ being very readily formed. This basic sulphate can be completely decomposed by heating it together with a solution of sodium carbonate and transformed into white lead. This process enables the lead sulphate obtained as a bye-product in cloth printing works, in the preparation of the red mordant, to be transformed with profit into saleable white lead. It is, of course, understood that the sulphate can also be produced at will from litharge or from sugar of lead or lead nitrate, and treated so as to obtain white lead at a comparatively low price. Claim: The process of transforming lead sulphate first into basic sulphate, preferably into $2PbSO_4,Pb(HO)_2$, by heating it with caustic alkaline lye, and then into white lead, by heating the basic sulphate with carbonate of sodium.—No. 16706. October 22nd. 1889. 6*d*.

PURIFYING AND PRESERVING MILK.—*J. T. Appleberg, Knoxville, U.S.A.*—The method consists in heating the milk to a sufficiently high temperature to destroy the bacteria, &c., contained in it. The apparatus used consists of a square box, whose front and top are hinged. In the bottom of the box is a coil of tubing upon which the receptacle containing the milk rests. A small aperture is made in the top of the box to admit a thermometer to the mouth of the milk receptacle immediately beneath. The milk receptacle is placed upon the coil, the lids of box closed, and the thermometer placed through the aperture at the top into the body of the liquid. Steam is then passed through the coils, heating the milk rapidly to 160° Fahr., and more slowly until it reaches 190°, and after standing at this heat for a sufficient length of time the steam is cut off, the milk removed, and the receptacles closed ready for shipment, &c. Two claims are made.—No. 1328. January 25th, 1890. 8*d*.

STEEL.—*J. Riley, Glasgow.*—The improved steel or steel-like compounds are manufactured in a crucible, Bessemer converted, or open-hearth furnace, but preferably in the latter. When using a crucible, nickel is added in the form of bars, cakes, or granular pieces mixed with iron or steel scrap. When the contents are melted, a proportion of ferro-manganese is added, and finally some metallic aluminium. In a converter the charge of metal is decarbonised to the required extent, and sufficient ferro-manganese added to insure deoxidation, and then nickel; subsequently ferro-manganese is added, and immediately after aluminium or its alloy. The method of proceeding with an open-hearth furnace is that usually adopted in the manufacture of steel until a proper degree of decarbonisation of the charge has been reached, when a sufficient quantity of ferro-manganese is added to ensure deoxidation. Next nickel is added, and then again ferro-manganese, and finally aluminium or its alloy. Instead of introducing nickel alone, a compound of nickel, copper, and iron may be used, and preferably the compound produced as a matte in the primary smelting of ores. Four claims are made for the above-described methods of making steel or steel-like compounds.—No. 8492. May 22nd, 1889. 6*d*.

ETHYL-MERCAPTAN.—*C. J. Steinhart, London.*—Chemically pure ethyl-mercaptan is obtained by this invention from methylated spirits, instead of, as hitherto, from strong pure alcohol. One part by weight of ordinary methylated spirits is mixed with two of concentrated sulphuric acid, and the mixture gently heated for one hour. The mixture is then slowly poured into about three times its bulk of cold water, and carefully neutralised with carbonate of potash. The neutralised solution is next evaporated, and thus the greater part of the alkaline sulphate, as well as resinous matter due to the impurities in the wood spirit, are eliminated. The solution remaining is mixed with a strong aqueous solution of hydrosulphide of potassium. The product thus obtained may be separated by distillation into methyl-mercaptan and ethyl-mercaptan. The resulting ethyl-mercaptan may be freed from remaining portions of the methyl compound and other impurities by fractional distillation. The process may also be conducted in the following manner:—The methylated spirits are saturated with hydrochloric acid. A gaseous ethyl-chloride, contaminated with methyl-chloride, results, which upon further treatment with alcoholic solution of sulphydrate of potash yields an impure mercaptan. Claim: The manufacture ot pure ethyl-mercaptan from commercial methylated spirits, by transforming the methylated spirit into either sulpho-vinate of potash or into ethyl-chloride, treating the same with hydrosulphide of potassium (in aqueous or alcoholic solution), heating the resultant liquid, and finally dis illing the same, all as set forth.—No. 6494. April 16th, 1889. 4*d*.

NEW RED COLOURING MATTERS.—*S. Pitt, London. (L. Casella & Co., Frankfort-on-Main.)*—In the class of azo colours derived from benzidine and other paradiamines red colouring matters have only been obtained by combining the amines with naphthylamine sulpho acids. The combinattion of paradiamines with naphthols or their sulpho acids yields but blue to violet colours. The inventors have found a method to get brilliant red colouring matters from naphthols and benzidine or its homologues. 18·4 kilos of benzidine are diazotised and added to a cooled solution of 40 kilos of β naphthol γ disulphonate of sodium; after a short time 10 kilos of phenol are introduced, then heated to boiling, and the colouring matter is precipitated by common salt and separated by filtration. The precipitate is again dissolved in 200 litres of water and 200 kilos of alcohol, with 4·5 kilos of caustic soda, and heated together with 12 kilos of ethylbromide during 24 hours in a closed vessel to about 60° C. After cooling the new colouring matter separates in shining crystals. Instead of benzidine other paradiamines, such as methylbenzidine, toluidine, instead of γ naphthol disulphonate, β naphthol α monosulphonate and instead of phenol cresol may be employed with a similar result. Claims: (1) The process substantially as described for the production of red colouring matters by alkylating or benzylating the substances formed by the combination of one molecule of β naphthol α monosulphonate or γ disulphonate and of one molecule of phenol or cresol with one molecule of tetrazo-diphenyl or its homologues; (2) as new articles of manufacture the red colouring matters obtained by the said process.—No. 12560. August 8th, 1889. 4*d*.

MISCELLANEOUS.

COKE OVENS.—*A. M. Chambers, Thorncliffe, & T. Smith, Chapelton.*—These improvements in coke ovens are to better the quality of the coke and obtain larger pieces. The improvements are specially adaptable to coke ovens constructed according to a previous patent, No. 7385 of 1885. The volatile and other liquids such as tar, produced from the carbonisation or coking of the coal, are discharged by a pipe below the floor of the oven near its front and an opening at the back of the oven near its top. The second opening is surrounded by a straight or conical pipe of fireclay. The two pipes lead to a condenser by which the products are collected for utilisation. By means of these pipes the products evolved in the carbonisation of the coal are partly discharged at the top and partly at the bottom of the oven. In this method of coking a more uniform heat is produced throughout the whole mass of the coal from the beginning to the end of the process, and permits the use of inferior classes of coal and slack in coking. Two claims are made.—No. 7424. May 3rd, 1889. 8*d*.

PRESERVING GRASS, &c.—*T. Pearson, Wolverhampton.*—The grass is preserved as ensilage for cattle in the following manner:—It is first placed in a silo or other receptacle of any form, and the receptacle sealed. Air is then exhausted from the receptacle by means of a fan or pump worked from the outside. The air thus drawn off effects the preservation of the contents. The grass may be rolled or compressed in addition to rarefying the surrounding air. By exhausting the air from the receptacle, the temperature and fermentation of the contents may be regulated or destroyed. Claims: (1) The use of a silo or receptacle, of any form or structure, air-tight or nearly so, in combination with an exhaust fan or equivalent appliance and connecting pipe with valve or tap, to draw off or expel the air or vapour in said silo, for the effective preservation of the contents as silage or food for cattle, &c.; (2) the use of silo or receptacle, with exhaust fan and connecting pipes, &c., having outlets or drains to open and shut for the emission of fluids or juices from the contents.—No. 4363. March 13, 1889. 6*d*.

ANNEALING FURNACES.—*A. W. Turner, Birmingham, & G. Tomkinson, Oldbury.*—The furnace is designed for annealing sheet castings and other metallic bodies in the process of manufacture. It is built of two side and two end walls forming the outer room of the furnace; within this room are built one end and two side partitions forming an inner room of smaller dimensions. The side partitions are pierced or provided with a series of holes, and in the space between the back end of partition and the outer room is the heating furnace. The spaces between the side partitions and the outer room communicate with the space containing the heating furnace. The entrance is at the end opposite the furnace, and upon each side of the entrance are flues for conveying away the fumes from the furnace. The products of combustion are thus passed from the furnace to the back of the side partitions, through which they percolate to the inner chamber and then travel towards the entrance and away by the flues upon both sides. Claim: The making of an annealing furnace with the walls of the inner room built up to the roof or top of the furnace, such inner walls being perforated with holes or passages, so that the flames and heated gases produced on the fire-grate of the furnace will be compelled to pass through the perforations formed in the walls of such inner room in order to reach the flue or flues connected with the stack.—No. 5138 March 26th, 1889. 8*d*.

FILTER PRESSES.—*J. Hill, Stoke-on-Trent.*—The presses referred to in this invention are those used for making potters' clay, compressing yeast, or such like purposes. The chief feature of this invention is in the method of constructing the presses with porous slabs which can be removed and reversed so that the liquid flows through them alternately in opposite directions. A press so constructed consists of several sections, each formed of two or more porous tiles of suitable thickness carried in a wooden or other frame. These tiles are bolted or cramped together side by side so as to leave spaces between each set. The slurry or other semi-fluid is forced into the said spaces between the sets of tiles. The liquid escapes through the tiles and the solid matter is retained and compressed in the spaces. When the spaces have become filled with solid matter the slabs and the solid matter are removed from the press. The slabs are then replaced with their surfaces reversed so that the liquid passing through the slabs in a contrary direction tends to force out any solid matter that has blocked up the pores from the previous operation. Three claims are made.—No 7087. April 29th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

MUMFORD & MOODIE'S SEPARATOR.

We illustrate herewith Mumford & Moodie's patent separator for separating hard substances and obtaining a uniform fine product. Briefly described, it is an apparatus wherein a current of air circulating continuously through a descending stream of ground material separates the finer particles from the coarser, the latter being then returned to the pulveriser, millstones, or other grinding machinery, to be further reduced. In Fig. 1 we show a section of the apparatus, which is made of cast iron. The outer casing A collects the finer dust, which falls to the spout at the bottom, and is collected in bags or casks, as desired, while the coarse particles fall into the inner casing B, and are delivered to the right and left through the branch pipes *a a*, by moving the valve *c*. The material is thrown against the hood D, which is made in different sizes and forms, so as to

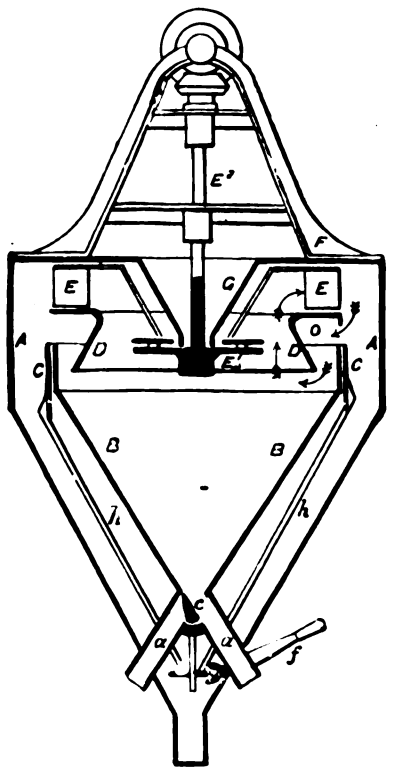

Fig. 1.—Vertical Section.

vary the degree of separation and quality of the separated products. The blades of the fan E are connected by arms to the disc E^1, which is rotated by gearing attached to the fan spindle E_2.

The machine will be found useful in many industries, and we understand that it has already been supplied for separating the finer particles from the coarser in ground basic slag, chrome ore, gold quartz, cement, phosphates, limestone, coal, charcoal, coke, animal char, bones, paint, indigo, tanning materials, and for cleaning linseed and other seeds. It can be used in the place of sieving, and will be found to work more economically and with greater efficiency than any hand process. The makers are Messrs. Askham Bros. & Wilson, Limited, of Sheffield.

MUMFORD & MOODIE'S SEPARATOR.

THE INSTITUTION OF NAVAL ARCHITECTS.

(*Concluded from page* 365.)

The next paper read on the 28th ult. was by Mr. T. C. Read, on "The Variation of the Stresses on Vessels at Sea Due to Wave Motion." This paper deals with the dynamical effect on the longitudinal and other stresses, due to the vertical motion of vessels when among waves. The vertical oscillations caused by wave motion are due to the repetition of forces alternately raising and lowering the vessel; if these forces act at irregular intervals, the amplitude of the oscillations will not be so great as when the forces act at regular intervals, and further the maximum range will be reached when the natural dipping period of the vessel and the period of action of the disturbing forces are the same or nearly the same. The waves which will throw the greatest stresses on the structure are those of the same length as the vessel and having the maximum ratio of depth to length. For these reasons the vessels considered are supposed to be placed bows on to a regular series of waves of their own length. Owing to the fineness of the ends the vessel will sink deeper into the wave when the ends of the vessel are in the crests and the trough amidships than when the crest is at the middle of the length of the vessel. There will therefore be, as the waves pass the vessel, a reciprocating force acting on her, alternately raising and depressing the vessel, and it is the effect of the motion thus set up that is considered in this paper. The resistance of the water to this dipping motion is also an important factor in determining the range of the oscillations, and this part of the subject is dealt with in the latter part of the paper, the amplitude of the unresisted vertical oscillations being first investigated. The pitching and 'scending motion of the vessel is neglected, as it has no effect on the stresses at the midship section of the vessel.

Suppose the vessel to be in statical equilibrium, with its ends in the crests of a wave of its own length. As the wave passes the vessel, to maintain statical equilibrium the centre of gravity will rise, and will continue rising, until the crest reaches the middle of the length of the vessel. The equation of motion of the centre of gravity is given approximately by the equation $h = a \sin \pi t/T$, where T is the half period of the wave, and a = half the total rise or fall of the centre of gravity.

Now, if S be the actual position of the centre of gravity above the axis of t at any time t, then the upward force acting on the vessel at this instant will be

$$p\left(a \sin \frac{\pi t}{T} - s\right)$$

where p is the tons per foot immersion, which for the present is assumed to be constant near the water line. If, therefore, M be the mass of the vessel, the equation of motion will be

$$\frac{d^2 s}{d t^2} = \frac{p}{M}\left(a \sin \frac{\pi t}{T} - s\right)$$

The author then proceeded to solve this equation, but we cannot give more than the results. The maximum value of s occurs when

$$\cos \frac{\pi t}{T} = \cos \sqrt{\frac{p}{M}}\, t$$

and will therefore depend on the relative values of $\frac{\pi}{T}$ and $\sqrt{\frac{p}{M}}$. In a special vessel, the registered dimensions of which are 380ft. × 46ft. × 30ft., the moulded draught 24ft. and displacement 7,830 tons, the value $\frac{p}{M}$ is $\frac{390 \times 32}{7{,}830} = 1{\cdot}6$ approximately. The speed of trochoidal waves 380ft. long is about 26·6 knots per hour, and the still water speed of the vessel considered is 12 knots; consequently, 38·6 knots may be regarded as the greatest relative velocity of ship and waves. The minimum value of the virtual period of the waves is therefore $\frac{380 \times 60 \times 60}{38{\cdot}6 \times 6{,}080}$ = a little more than 5·8 seconds. Hence the maximum value of π/T is 1·083, and of π^2/T^2 1·173. The limiting positions of the vessel when on the crest is about 11½ft., or nearly 10ft. above the position of statical equilibrium. The lowest position when on the crest is found to be ·89ft.—*i.e.*, the vessel is ·76ft. below its position of statical equilibrium.

When the vessel is across the hollow of a wave an exactly similar process will show that the maximum depth reached is 11½ft. below the base line used, while the minimum depth will be ·89ft. or ·76ft. above the position of statical equilibrium.

As regards resisted motion the methods of calculation are very approximate owing to mathematical and experi-

Digitized by Google

mental difficulties. The value of the resistance at any velocity has been found thus: The length of the vessel was divided into several parts according to the shape of the bottom; the midship portion was then taken as flat; lengths before and abaft the midship part as semi-circular in section; before and abaft these, lengths were taken as represented by parts of circles of radius = the breadth of the vessel meeting at the keel, and finally for the ends wedges of a suitable angle. Summing the results thus obtained the resistance to the vessel entering the water at a speed of 12ft. per sec. (downward velocity) is estimated as 450 tons, and this resistance varies practically as the square of the speed. Introducing, then, the factor of resistance, the equation of motion becomes:—

$$\frac{d^2 s}{d t^2} = \frac{p}{M}\left(a \sin \frac{\pi t}{T} - s\right) \pm \frac{R}{M}$$

This does not admit of an exact solution, and the method of graphic integration has, therefore, been adopted. The author then illustrated the variation in the results by means of diagrams for which we have not sufficient pace here.

The author then proceeded to find the effect of oscillations on the stresses, and considered first the vessel on the crest of the wave. The centres of buoyancy of the fore and after bodies of the fine vessel when in statical equilibrium are found to be 120ft. apart. The positions of the centre of gravity of weight of the fore and after bodies will, of course, depend upon the stowage of the cargo, but if it be assumed that the statical bending moment for this vessel is the displacement × one-fortieth of the length, the distance between the centres of gravity required will be 158ft. Now suppose the vessel in its limiting position—that is, 9·2ft. above the base line, or 7·55ft. above the position of statical equilibrium. The centres of buoyancy of the fore and after halves of the layer of displacement lost will be 143ft. apart, and the buoyancy lost = 2,550 tons. The weight of the vessel determining the longitudinal bending moment will therefore be reduced to 7,830 − 2,550 tons = 5,280 tons. The distances apart of the centres of buoyancy for the reduced displaced will be 106ft., so that the

$$\text{Bending moment} = \frac{5{,}280}{2} \times \frac{158 - 106}{2} = 68{,}640 \text{ ft. tons.}$$
$$= D \times 8{\cdot}77$$

The statical bending moment is assumed to be = D × 9·5. Hence the effect on the bending moment of this position of the vessel is to reduce it by about 7·7 per cent. In a similar manner the effect on a statical bending moment of different value may be found and the effect on the sagging moment of the vessel being immersed below its position of statical equilibrium. These results have been worked out for sagging and hogging moments of $\frac{D\,l}{40}$ and $\frac{D\,l}{50}$ for each of the vessels considered, and the results are given in the following table:—

			Fine Vessel.		Full Vessel.
Tonnage coefficient			0·67	...	0·79
Percentage decrease of hogging moments when at maximum elevation over crest	Statical moment	$= \frac{D\,l}{40}$	7·7	...	4·2
	Statical moment	$= \frac{D\,l}{50}$	1·5	...	0·0
Percentage increase of sagging moments when at maximum depression in hollow	Statical moment	$= \frac{D\,l}{40}$	24·1	...	10.7
	Statical moment	$= \frac{D\,l}{50}$	21·0	...	8·4

It is only the cases where increases in the stresses occur which have any value, since, from what has previously been shown when dealing with unresisted rolling, the hogging stresses may be slightly increased beyond the statical values, owing to the vessel when at her minimum height being a little below her position of statical equilibrium. As regards the sagging stresses, it is interesting to note that the increase to the fine vessel is more than double that to the full vessel.

In the discussion which followed, Professor Jenkins said his mind was carried back to a period when Mr. Read and he jointly undertook the investigation of this subject. They had not proceeded far when they found there was an absence of experimental data upon which to work. Their method was not so good as that now adopted. In his own paper the day before he had made some remarks upon the behaviour of a vessel on a series of waves. Those remarks were somewhat general, and he was glad to find that in the main they had been borne out by the detailed calculations of the present paper. When a vessel was crossing a series of waves, she behaved very much as a vessel rolling in the trough. The amplitude of her oscillations would grow, reach the maximum, and then decrease and become almost *nil*, and then begin increasing again. It had long been a point for discussion as to how far the bending moment borne by the vessel was affected by this oscillation, and they found that when a laden vessel was poised on the crest of a wave, there was an actual decrease in the bending moment; while, when she passed beyond that position in the other direction, with the increased water support, there was also an increased bending moment. The consideration which governed this question was entirely one of the longitudinal positions of the centre of gravity. At first sight it would be thought that the fine vessel had a bad time on the crest of a wave. The displacement of the fine vessel was very much smaller than that of the full vessel, and, if they allowed for that, the fine vessel would still have the same advantage over the full vessel with regard to the longitudinal bending moment. He hoped the paper would induce more people to take up the question of vertical resistance.

Mr. Martell said no one knew better than he the labour required in getting out these results. The work was more important to them, because, as many would know, Lloyd's had been pressed to make some reductions in the scantlings of fine vessels as compared with full ones. Their experience had taught them, and these calculations confirmed the view, that fine clipper ships were more liable to alter their form owing to the stress brought on them at the ends, and, therefore, they had refused to diminish the scantlings.

Mr. Biles thought they should not accept too rashly all the conclusions brought out in this paper. Mr. Martell said they confirmed him in his objections to reducing the scantlings of fine-ended ships. There were, however, too many assumptions to arrive at definite conclusions. If a section is considered which is not the midship one, the strains of pitching and 'scending are much more than the total moments of inertia and the difference due to the ends. A ship must be fully laden before any such deductions can be drawn at all. The bending moments had been assumed to be the same for fine-ended and full-ended ships, but they were really not so. The resistance must be found for a ship moving vertically. There was the resistance also of the vertical movement of the propeller, and it was more in full ships than in fine ships.

Mr. A. Denny was of opinion that fine-ended ships could be built of lighter scantlings, and he was willing to build such a ship on trial, because he was quite sure of his results.

The next paper read was by Professor Vivian B. Lewes, on "The Spontaneous Ignition of Coal Cargoes." We give this paper in full as follows:—

Fifteen years ago the loss of life and property caused by the spontaneous ignition of coal cargoes became so serious that the Board of Trade, acting in unison with the Committee of Lloyd's, urged upon the Government the necessity for appointing a Royal Commission to inquire into and report upon the *possibility of preventing a class of disaster* as appalling in nature as it is destructive in result. The Commission, which was appointed in April, 1875, had the good fortune to be aided in their inquiry by the scientific knowledge of Dr. Percy and Mr. (now Sir Frederick) Abel, and after collecting and collating all the evidence which could be obtained, they in the following year published their report upon the subject. In this report much valuable evidence is passed in review, and much sound advice is given for the guidance of those employed in the shipment of coals; but whether it is that the sight of a blue book scares the ordinary reader, or that the circulation of such literature, often of the most valuable character, is of necessity very limited, the fact remains that the conditions at present existing are nearly as bad as they were before the publication of the report. In the nine years immediately following the report—viz., 1875 to 1883—57 coal-laden vessels are known to have been lost from spontaneous ignition of their cargoes, whilst during the same period 328 were missing from unknown causes, a large percentage of these losses being undoubtedly due to the same cause; and these, again, form but a very small percentage of the cases in which cargoes have heated and fired, but in which the vessel has been saved; and now, within the last few years, the statement has gained ground that with the general increase of temperature in steamships, due to the introduction of triple-expansion engines and high-pressure boilers, spontaneous firing in the coal bunkers and coal cargoes is very much increased, and that many accidents arise from this cause. Under these circumstances, Mr. Martell suggested to me some time ago that an inquiry into the causes and possible prevention of this very serious evil would be work, not only likely to be acceptable to the members of this Institution, but also one that was needed in the Service, as well as in the mercantile marine; and I have now much pleasure in bringing before you the results obtained in a long series of experiments, and which, taken in conjunction with the work done by others on the subject, throws a somewhat clearer light upon the causes of this particular class of phenomenon, and enables suggestions to be made for its prevention.

Coal is a substance of purely vegetable origin, formed out of contact with air by long exposure to heat and pressure, from the woody fibre and resinous constituents of a monster vegetation which flourished long before the earth was inhabited by man; and coal may therefore be looked upon as a form of charcoal, which having been formed at a temperature lower than that of the charcoal burner's heap and under great pressure, is very dense, and still retains a quantity of those constituents which, in the latter case, are driven off, as tar, wood naphtha, &c.; and these bodies consist essentially of compounds containing carbon and hydrogen, together with a little oxygen and nitrogen, and form the volatile matter and hydro-carbons of the coal. Besides the carbon and hydro-carbons, coal also contains certain mineral bodies, which were mostly present in the sap and fibre of the original vegetation, and which give the ash which is left behind when the coal is burnt. These substances consist chiefly of sulphate of lime or gypsum, silica, and alumina, whilst in nearly all kinds of coal is to be found a substance called disulphide of iron, coal brasses or pyrites, which has been formed by the gradual reduction of the sulphates by carbonaceous matter in the presence of iron salts, and which, during the combustion of the coal, is decomposed, giving off sulphur compounds and leaving behind oxide of iron, which gives the reddish brown colour to the ash left by many kinds of coal. Of these constituents of coal, the only ones which play no part in the phenomena attending heating and spontaneous ignition, are the mineral constituents other than the pyrites, and we have therefore to deal with the chemical actions which take place when the carbon, hydro-carbons, and brasses contained in newly won coal come in contact with air and moisture.

The Influence of Carbon in Producing Heating.—Carbon is one of those substances which possess to an extraordinary degree the power of attracting and condensing gases upon their surface, this power varying with the state of division and density of the particular form of carbon used. The charcoal obtained from dense forms of wood, such as box, exhibit this property to a high degree, one cubic inch of such charcoal absorbing:—

Ammonia gas	90	cubic inches.
Sulphureted hydrogen	55	,,
Carbon dioxide	35	,,
Ethylene (olefiant gas)	35	,,
Oxygen	9·25	,,
Nitrogen	6·5	,,

whilst certain kinds of coal also exhibit the same power, although to a less degree. The absorptive power of newly won coal due to this surface attraction varies, but the least absorbent will take up 1¼ times its own volume of oxygen, whilst in some coals more than three times their volume of the gas is absorbed. This absorption is very rapid at first, but gradually decreases, and is moreover influenced very much by temperature, for reasons which will be explained later. The absorption is at first purely mechanical, and itself causes a rise of temperature, which, in the case of charcoal formed in closed retorts, as in preparing alder, willow, and logwood charcoal for powder making, would produce spontaneous ignition if it were not placed in sealed cooling vessels for some days before exposure to air. The rate of absorption varies with the amount of surface exposed, and therefore able to take part in this condensing action, so that when coal or charcoal is finely powdered, the exposed surface being much greater, absorption becomes more rapid, and rise of temperature at once takes place. If charcoal is kept for a day after it has been made out of contact with air, and is then ground down into a powder, it will frequently fire after exposure to the air for thirty eight hours; whilst a heap of charcoal powder, of 100 bushels or more, will always ignite. It is for this reason that, in making the charcoal for powder, it is always kept, after burning, for three or four days in air-tight cylinders before picking over, and ten days to a fortnight before it is ground. In the case of coal, this rise in temperature all tends to increase the rate of the action which is going on; but is rarely sufficient to bring about spontaneous ignition, as, only about one-third the amount of oxygen being absorbed by coal that is taken up by charcoal, and the action being much slower, tends to prevent the temperature reaching the high ignition point of the coal. Air-dry coal absorbs oxygen more quickly than wet coal.

The Action of the Bituminous Constituents of the Coal in Spontaneous Ignition.—All coal contains a certain percentage of hydrogen, which is in combination with some of the carbon, and also with the nitrogen and oxygen, and forms with them the volatile matter in the coal, and the amount present in this condition varies very largely, being very small in anthracite and very great in cannel and shale. When the carbon of the coal absorbs oxygen, the compressed gas becomes very chemically active, and very soon commences to combine with the carbon and hydrogen of the bituminous portions, converting them into carbon dioxide and water vapour. This chemical activity increases rapidly with rise of temperature, so that the heat generated by the absorption of the oxygen causes it to rapidly enter into chemical combination. Chemical combination of this kind—*i.e.*, oxidation—is always accompanied by evolutions of heat, and this further rise of temperature again increases rapidly of oxidation, so that a steady rise of temperature is set up, and this taking place in the centre of a heap of small coal, which, from the air and other gases enclosed in its interstices, is an admirable non-conductor of heat, will often cause such heating of the mass that if air can percolate slowly into the heap in sufficient quantity to supply the necessary percentage of oxygen for the continuance of the action, the igniting point of the coal would be soon reached. The effect of rise of temperature in increasing the rapidity of chemical actions of this kind can be realised from the effect which it has in the spontaneous ignition of oily waste or rag. If a substance like cotton waste be rendered oily with anything except the mineral oils, it acquires the power of taking up oxygen from the air, and this oxidising the oil gives rise to heat. At ordinary temperatures this oxidation is slow, and, consequently, it may be days before the rise in temperature becomes sensible, but when this point is reached the oxidation proceeds with remarkable rapidity, and in a few hours the point of ignition is reached and the mass bursts into flame, whilst if the oily waste be placed in a warm place at first, spontaneous ignition is only a question of hours or sometimes even minutes. Galletley found that oily cotton at ordinary temperatures took some days to heat and ignite, whilst placed in a chamber warmed to 130° to 170° F. (54° to 76° C.), the cotton greasy with boiled linseed ignited in one hour fifteen minutes, and olive oil on cotton in five hours, and in a chamber heated to 180° to 200° F. (82° to 93° C.) olive oil on cotton ignited in two hours. It has been suggested that very bituminous coal, such as cannel, shale, and coals containing schist, is liable to spontaneous ignition from the fact that a rise in temperature would cause heavy oils to exude from them, which, by undergoing oxidation, might cause rapid heating. But experiment not only shows that it is not the case, but that the heavy mineral oils have a remarkable influence in retarding heating, cotton waste, oily with easily oxidisible oils mixed with 20 per cent. of heavy mineral oil, being exempt from heating.

The Action of Iron Disulphide, Pyrites, or Coal Brasses in Promoting Spontaneous Ignition.—Ever since Berzelius first expressed the opinion that the heat given out by the oxidation of iron disulphide into sulphates of iron might have an important bearing on the heating and ignition of coal, it has been adopted as the popular explanation of that phenomenon; and although the work of Dr. Richters clearly proves this not to be the case, the

* Maximum temperature during voyages from Portsmouth to Bombay.

NOTE.—The registers of the original engines of "Malabar" are destroyed; temperature records of "Crocodile" are given in lieu for a period when she was fitted with old low-pressure engines.

old explanation is still given, a notable exception, however, being in the case of our great metallurgist, Dr. Percy, who, as early as 1864, pointed out that probably oxidation of the coal had also something to do with spontaneous combustion, a prediction amply verified by Dr. Richters' researches some six years later. This disulphide of iron is found in coal in several different forms, sometimes as a dark powder distributed throughout the mass of the coal, and scarcely to be distinguished from coal itself. In larger quantities it is often found forming thin golden-looking layers in the cleavage of the coal, whilst it sometimes occurs as large masses and veins, often 1in. to 2in. in thickness, but inasmuch as these masses of pyrites are very heavy, they rarely find their way into the screened coal for shipment, many hundreds of tons of these "brasses" being annually picked out from the coal at the pit's mouth, and utilised in various manufacturing processes. If the air is dry the pyrites undergo but little change at ordinary temperatures; but in moist air they rapidly oxidise when in a finely divided condition, the first action being the formation of ferrous sulphate and sulphur dioxide, together with the liberation of sulphur, the relative amounts of the two latter being regulated by the temperature and the supply of air, whilst longer contact with moist air converts the ferrous sulphate into a basic ferric sulphate generally termed "misy." It is during this process of oxidation that the heat supposed to cause the ignition is evolved. But when it is considered that some of the coals most prone to spontaneous combustion contain only eight-tenths of 1 per cent. of iron pyrites, and rarely more than 1¼ per cent., the absurdity of imagining this to be the only cause of ignition becomes manifest. If 100lb. of coal were taken, and the whole of the pyrites in it concentrated in one spot and rapidly oxidised to sulphate, the temperature would barely be raised to 100° C., if all loss of heat could be avoided. Besides which, in certain manufactures pure iron pyrites are largely used, and, when free from carbonaceous matter, may be kept in a state approaching to powder in heaps containing many hundred tons; and although undergoing continual oxidation, I have been unable to trace a single case of heating, much less a rise of temperature which would approach the igniting point of coal. When, however, it is mixed with finely divided carbonaceous matter, then heating and ignition is a frequent occurrence in even moderate sized heaps.

I have carefully determined the igniting point of various kinds of coal, and find that—

Cannel coal	ignites at 698 degrees F.	= 370 degrees C.	
Hartlepool coal	,, 766 ,,	= 408	,,
Lignite	,, 842 ,,	= 450	,,
Welsh steam coal	,, 870·5 ,,	= 477	,,

So that no stretch of imagination could endow the small trace of pyrites scattered through a large mass of coal, and undergoing slow oxidation, with the power of reaching the needful temperature. Dr. Richters fully realises this point, and discards the idea of the pyrites doing anything more than adding their mite to the causes which bring about rise of temperature. In this, however, I think he is mistaken, my experiments, which will be published when complete, pointing to the fact that they may increase the liability to ignition when present in large quantities, and do so by liberating sulphur under certain conditions. Now, sulphur has an igniting point of 482° F. or 250° C., so that the presence of free sulphur would lower the ignition point of the coal by considerably over 100 degrees Centigrade, the sulphur in this case playing exactly the same part that it does in gunpowder, in which it lowers the point of ignition and increases the rapidity of combustion. A still more important part played by the pyrites is that as they become oxidised to ferrous sulphate they swell in size, and so tend to split up the coal into small pieces, and by exposing a large extent of fresh surface to the air cause increase of temperature and energetic chemical action.

We can now trace the actions which cumulate in ignition. The newly won coal is brought to the mouth of the pit, and at once commences by virtue of its surface action to absorb oxygen from the air, but unless piled in unusually large heaps, and a good deal broken, it does not, as a rule, show signs of heating, as the exposed surface is comparatively small, and the air finding its way freely between the lumps keeps down the temperature. The coal is now screened, and the obtrusively large lumps of brasses picked out; it is then put in the trucks and enjoys the disintegrating processes of joltings and shuntings innumerable, every jar adding to the percentage of small coal present, and a corresponding increase in the size of the surface exposed to the air. Arrived at the docks it has to be transferred from the truck to the ship, which is done by one of the numerous forms of tips, shoots, or spouts employed for the purpose, and it is during this operation that more harm is done than at any other period. The coal first shot into the vessel by reason of the distance which it has to fall is broken down into small lumps, and having to bear the impact of the succeeding load falling upon it from a height, rapidly becomes powdered into slack, whilst the succeeding loads falling in on the cone so formed get more or less broken down, so that by the time the cargo is all taken in, a dense mass of small coal is to be found under the hatchway, and it is invariably at this point that heating takes place, as the large surface exposed fresh to the air by the breaking down of the coal causes rapid absorption of oxygen, and consequent rise of temperature. This sets up chemical combination between the oxygen absorbed by the coal and the hydrocarbons and coal brasses. The combination of the brasses with oxygen causes the swelling of the oxidised mass and splitting up of the coal; fresh surfaces are exposed, and more absorption of oxygen takes place, and the igniting point of the sulphur vapour and sulphur compounds distilled out of the pyrites is reached, and rapidly raises the temperature to the ignition point of the coal. It is only in cases where large quantities of dense coal brasses are present that this action can take place, as in the ordinary case, where 1 or 2 per cent. only of pyrites are present, the sulphur vapour distilled out from the pyrites is oxidised to sulphur dioxide at temperatures far below the point of ignition of sulphur vapour; and in such cases the heat of absorption and oxidation of the bituminous portions of the coal is amply sufficient to raise the temperature to the requisite 752° to 932° Fahr. (400° to 500° C.).

On examining the evidence to be obtained as to the conditions under which spontaneous ignition of coal in ships usually takes place, it is found that liability to ignition increases with:—

1. *The Increase in Tonnage of Cargoes.*—Thus, in cargoes of under 500 tons the cases reported amount to a little under ¼ per cent. for shipments out of Europe; from 500 to 1,000 tons, to over 1 per cent.; from 1,000 to 1,500 tons, to 3·5 per cent.; 1,500 to 2,000 tons, to 4·5 per cent.; and over 2,000 tons, to no less than 9 per cent. The evidence demonstrating this very remarkable result is to be found in the Report of the Royal Commission for 1875, p. viii., and clearly shows the influence of mass upon this action which acts in two ways:—(*a*) The larger the cargo, the more non-conducting material will there be between the spot at which heating is taking place and the cooling influence of the outer air. (*b*) The larger the cargo the greater will be the breaking-down action of the impact of coal coming down the shoot upon the portions first loaded into the ship, and the larger therefore the fresh surface exposed to the action of the air.

2. *The Ports to which Shipments are made*—26,631 *shipments to European ports in* 1873 *only resulting in ten casualties, whilst* 4,485 *shipments to Asia, Africa, and America gave no less than sixty.*—This startling result is partly due to the length of time the cargo is in the vessel, the absorption and oxidation being a comparatively long action, but a far more active cause is the increase in the action brought about by the increase of temperature in the tropics, which converts a slow action into a rapid one, and if statistics had been taken, most of the ships would have been found to have developed active combustion somewhere about the neighbourhood of the Cape, the active action developed in the tropics having raised the temperature to the igniting point of the coal by that time.

3. *The Kind of Coal of which the Cargo consists—some coals being specially liable to spontaneous heating and ignition.*—This is a point on which great diversity of opinion exists, but I think it will be pretty generally admitted that cases of heating and ignition are more frequent in coals shipped from East Coast ports than in shipments of the South Wales coals. As has been pointed out, however, so much depends on the amount of small coal present that a well-loaded cargo of any coal would be safer than a cargo

Digitized by Google

of Welsh steam coal in which a quantity of dust had been produced during loading. The idea that the percentage of pyrites present is any indication of the liability to spontaneous combustion must be entirely discarded, as experiment shows that many coals poor in pyrites frequently ignite, whilst others rich in them are perfectly safe. A much surer guide is to be found in the quantity of moisture present in an air-dried sample of coal, which is a sure index to the absorptive power, the higher the amount of moisture held by the coal after exposure for some time to dry air, the greater will be its power of absorption for oxygen, and the greater therefore its liability to spontaneous heating and ignition. This is shown by the following table, in which the percentage of pyrites and moisture present in some coals are contrasted with their liability to self-ignition:—

Liability to Spontaneous Ignition.	Pyrites per Cent.		Moisture per Cent.
Very slight	1·18	...	2·54
	1·01 to 3·04	...	2·75
	1·51	...	3·90
Medium	1·20	...	4·50
	1·08	...	4·55
	1·15	...	4·75
Great	1·12	...	4·85
	0·83	...	5·30
	0·84	...	5·52
	1·00	...	9·01

4. *The Size of the Coal—small coal being much more liable to spontaneous ignition than large.*—This, as has been pointed out, being entirely due to the increase in active absorbent surface exposed to the air, a fact which is verified by the experience of large consumers of coal on land; gas managers recognising the fact that coal which has been stamped down or shaken down during storage being more liable to heat than if it has been more tenderly handled, the extra breakage causing the extra risk.

5. *Shipping Coals rich in Pyrites whilst Wet.*—The effect of external wetting on coal is to retard at first the absorption of oxygen and so to check the action, but it also increases the rate of oxidation of the pyrites, and so causes disintegration of the coal, with consequent crumbling and heating due to exposure of fresh dry surfaces.

6. *Ventilation of the Cargo.*—The so-called ventilation which has from time to time been introduced into coal ships is undoubtedly one of the most prolific causes of spontaneous ignition. For ventilation to do any good, cool air would have to sweep continuously and freely through every part of the cargo, a condition impossible to attain, whilst anything short of that only increases the danger, the ordinary methods of ventilation supplying just about the right amount of air to create the maximum of heating. The reason of this is clear. A steam coal absorbs about twice its own volume of oxygen, and takes about ten days to do it under favourable conditions, and it is this oxygen which in the next phase of the action enters into chemical combination and causes the serious heating. A ton of steam coal occupies 42 to 43 cubic feet, and if properly loaded contains between the lumps as nearly as possible 12 cubic feet of air space—that is to say, of the 42 cubic feet, 12 cubic feet is air and 30 cubic feet is coal. Thirty cubic feet of coal, with its fresh absorbing surfaces laid bare by the crushing incidental to loading, will, in the first ten days after being taken on board, absorb 60 cubic feet of oxygen, if it can get it. Now, air contains only, roughly, one-fifth of its volume of oxygen, so that 60 cubic feet represent 300 cubic feet of air, or twenty-five times as much as is present; so that it is evident that if air could be excluded there would be only one twenty-fifth the quantity of oxygen present which is needed for complete action, and any heating would, in consequence, be very slight; whilst to produce the greatest heating it would be necessary to change the entire air in the cargo twenty-five times in the first ten days, and this is just about what the ordinary method of taking a box shaft along the keelson with Venetian lattice upshafts from it would give. The most forcible illustration of the evil of such ventilation is to be found in the case of the four colliers, "Euxine," "Oliver Cromwell," "Calcutta," and "Corah," which were loaded at Newcastle under the same tips, at the same time, with the same coal, from the same seam. The first three were bound for Aden, and were all ventilated. The "Corah" was bound for Bombay, and was not ventilated. The three thoroughly ventilated ships were totally lost from spontaneous ignition of their cargo, whilst the "Corah" reached Bombay in perfect safety.

7. *Rise in Temperature in Steam Colliers due to the introduction of Triple-expansion Engines and High-pressure Boilers.*—It has been fully pointed out that anything which tends to increase of initial temperature increases the rapidity of chemical action. Steam at 80lb. boiler pressure has a temperature of 324° F. (162° C.), and a common stoke-hold temperature with boilers worked at this pressure is 100° to 130° F. (or 38° to 54° C.). Steam at a boiler pressure of 155lb. has a temperature of 368° F. (or 186° C.), and gives a corresponding increase of temperature in the stoke-hold and other adjacent portions of the vessel, the temperature in the stoke-hold under these conditions being from 110° F. (43·5° C.) to 140° F. (60°), an increase of about 10° F. It is, however, difficult in the mercantile marine to get a direct comparison of the increase in temperature due to this cause; but in the Service, some of the troopships have been from time to time refitted, and in the case of the "Malabar" and "Crocodile," the temperatures existing with the old simple low-pressure engines, the old compound engines, and the new triple expansion engines can be contrasted, and will be found in the Table on page 387, for which I am indebted to Mr. White. From this it will be seen that, taking the voyage through, the average increase of temperature in the stoke-hold from the use of the triple-expansion engines is about 5 degrees. This table is of great interest, as the temperatures taken during the outward voyage of the "Crocodile," December, 1883, point to the coals in the bunkers commencing to heat, and also illustrate where and at what temperature it commenced. Crossing the Bay, the stoke-hold and bunker temperatures agree fairly well, but entering the Mediterranean the stoke-hold, having become heated to 100° F. on the 12th, action commenced in the bunkers, and this rapidly raised their temperature higher than that of the stoke-hold, the action, however, not being violent, and the bunker temperature rapidly falling below that of the stoke-hold as the chemical action died away.

Having now discussed the chemical and physical conditions which lead to the phenomenon known as "spontaneous ignition," we can formulate precautions which will tend to prevent such disasters.

1. *The Choice of Coal for Shipment to Distant Ports.*—The coal should be as large as possible, free from dust, and with as little "smalls" as can be helped. It is better as free from pyrites as possible, in order to prevent disintegration after shipment, and it should contain when air-dried not more than 3 per cent of moisture.

2. *Precautions to be Taken during Shipment.*—No coal should be shipped to distant ports until at least a month has elapsed since it was brought to the surface at the pit's mouth. Every precaution should be taken to prevent breaking up of the coal whilst being taken on board, and on no account must any accumulation of fine coal be allowed under the hatchways. When possible the coal should be shipped dry, as external wet, by producing oxidation of the pyrites, causes disintegration.

3. *Precautions to be Taken on Board Coal-laden Ships.*—This phase of the question is undoubtedly the most important, and in order to ensure any successful treatment of the coal cargo at sea to prevent undue heating and ignition, the means adopted must be as nearly automatic in their working as possible, as it is useless to expect the master or any officer on board a collier during rough weather, &c., to comply with any instructions, such as daily taking the temperatures in various parts of the cargo, and so on. The coal compartments should be made gas-tight, as far as the bulkheads separating them from the rest of the ship is concerned; and as no difficulty is found in doing this when provision for forced draught is being made, no difficulty should be found in this case. When the coal has all been taken in, it should be battened down, and the hatches should not be again opened until the vessel reaches her destination, the only ventilation allowable being a 2in. pipe just inserted into the crown of each coal compartment, and led 12 feet up the nearest mast, the top being left open. This would be quite sufficient to allow free egress to any gases evolved by the coals, but would not allow undue access of air. Into the body of the coal cargo itself would be screwed, at regular intervals of about 6ft., iron pipes, closed at the bottom, and containing alarm thermometers, constructed in the following way: A long bulb of glass, containing mercury, has an insulated wire inserted into the quicksilver, and making contact with it, whilst the stem attached to the bulb has a second wire in it, so arranged that when a rise of temperature causes expansion of the mercury, in rising in the tube it makes contact, and the wires from these tubes are in connection with an electric bell, index board, and battery in the captain's room, so that the moment the temperature is reached to which the thermometers have been set, the bell rings, and will continue to ring until the temperature again sinks, the spot in which heating is taking place being indicated by the index board. In the evidence given before the Commissioners in 1875, Mr. J. Glover strongly advocated the use of carbon-dioxide, or carbonic acid gas, as it is more usually termed, for extinguishing ignition when it had broken out in a coal cargo, and for stopping heating when it had reached a dangerous pitch. His proposal was to generate the gas by the action of hydrochloric acid upon chalk, and to lead it by gas pipes to the compartment affected, and this gas, being heavier than air and a non-supporter of combustion, was to displace the air and its contained oxygen, and so to prevent further action by surrounding the coal with an atmosphere which could not carry on combustion. The idea was a good one, but there were many difficulties in the way of carrying it out, one being that for every thousand tons of coal carried, 80 cwt. of hydrochloric acid would have had to be shipped, also the gas could not have been driven down into the hold if any serious heating had taken place, as an up current would have been formed and would have carried it away, whilst in this state of gas it fails to give any great cooling effect, and so would have exercised but little influence upon the mass of red hot fuel. These objections weighed so strongly with the Commissioners that in their final report we find the following sentences:—"Several methods for generating carbonic acid gas and applying it to the ignited portion of a coal cargo have been proposed for our consideration. We consider, however, that although this gas might be useful by excluding atmospheric air (which is essential to support combustion), yet it will not, as water does, exert any very sensible cooling effect, *which is a point of vital importance in the case of a mass of ignited coal.* We are of opinion that water and steam are the only agents practically available for the purpose of extinguishing fire in coal cargoes." Applied in the way which was suggested, there is no doubt but that the carbonic acid gas would have been practically useless; but there is another way in which it could be used, which would make it a most powerful cooling agent, an instantaneous quencher of fire, and would prevent any further tendency to heat on the part of the coal treated with it. If carbonic acid gas is compressed under a pressure of 36 atmospheres at a temperature of 32° F. (0° C.), it is condensed to the liquid state, and can be obtained in steel vessels, closed with screw valves. On opening the valve some of the liquid is ejected into the air, and on coming into the ordinary atmospheric pressure, is in a moment converted into a large volume of gas. Conversion from the liquid to the gaseous state means the absorption of a large amount of heat, and so great is this that everything near the stream of new-born gas is cooled down, and some of the escaping liquid is frozen to a solid, having a temperature of - 78° C., or —108·4 F. This liquid carbonic acid gas is now extensively manufactured, and is used abroad to a large extent for aërating waters, driving torpedoes, and for freezing machines; and I should suggest its use in the following way for the checking of ignition in the coal cargo: The nozzle attached to the screw-valve on the bottle of condensed gas would have a short metal nose-piece screwed on to it, the tube in which would be cast in solid, with an alloy of tin, lead, bismuth, and cadmium, which can be so made as to melt at exactly 200° F. (93° C.). The valve would then be opened, and the steel bottle buried in the coal during the process of loading. The temperature at which the fusible metal plug will melt is well above the temperature which could be reached by any legitimate cause, and would mean that active heating was going on in the coal; and under these conditions the pressure in the steel cylinder would have reached something like 1,700lb., and the moment the plug melted the whole contents of the bottle would be blown out of it into the surrounding coal, producing a large zone of intense coal, and cooling the whole of the surrounding mass to a comparatively low temperature. The action, moreover, would not stop here, as the cold, heavy gas would remain for some time in contact with the coal, diffusion taking place but slowly through the small exit pipe. When coal has absorbed as much oxygen as it can, it still retains the power of absorbing a considerable volume of carbonic acid gas; and when coal has heated, and then been rapidly quenched, the amount of gas so absorbed is very large indeed, and the inert gas so taken up remains in the power of the coal, and prevents any further tendency to heating; indeed, a coal which has once heated, if only to a slight degree, and has then cooled down, is perfectly harmless and will not heat a second time. It is not by any means necessary to replace the whole of the air in the interstices of the coal with the gas, as a long series of experiments show that 60 per cent. of carbonic acid gas prevents the ignition of the most pyrophoric substances. One hundred cubic feet of gas can be condensed in the liquid state in a steel cylinder 1ft. long and 3in diameter, and it has been shown that a ton of coal contains air spaces equal to about 12 cubic feet; therefore, one of these cylinders would have to be put in for every 8 tons of coal, and these would be distributed evenly throughout the cargo and near the alarm thermometers, which would be set to ring a degree or two below the point at which the fusible plug would melt. The bell ringing in the captain's room would warn him that heating was taking place, and the bell would continue to ring until the cylinder had discharged its contents and had cooled down to a safe degree, so that the whole arrangement would be purely automatic, and yet the officers would know if everything was safe. This liquid is now being made at a comparatively cheap rate, and with any demand for it machinery could be put up at the principal coaling ports to charge empty cylinders at a very low rate, so that the initial cost of the steel cylinders once got over the expenses would not be worth considering, more especially as one, or two at most, would be likely to go off. If the precautions advocated were taken no danger could arise until the arrival of the ship at her destination, and the commonest precautions would then suffice. On removing the hatches, no naked light must be allowed near them, and no one must be allowed to descend into the hold until all the gases have had time to diffuse out into air. If the cylinders have gone off there will be but little fear of explosion, as a high percentage of the carbonic acid gas lowers the explosive power which the mixture of marsh gas (given off from some coals) and air possess; but the carbonic acid gas would overcome and suffocate a man descending into an atmosphere containing any considerable percentage of it. When a safety lamp, lowered into the hold, continues to burn as brightly as it did in the open air, then it is perfectly safe to descend. When once coal in a cargo has fired, pumping in water is of practically no use, as the fire is, as a rule, near the bottom of the mass of coal, and the flow of the water is so impeded that, in percolating through the interstices of the heated coal, it is converted into steam before it can reach the seat of combustion. The most effective way to apply water would be to have four 3in. pipes laid along the floor of the coal compartments, about 6ft. apart, these tubes having a ¼in. hole bored in the upper side every foot or so, and each pair of pipes coming through the bulkhead, and connecting on to two 6in. pipes passing through the side of the vessel, the sea water being prevented from entering by means of screw valves. As soon as the alarm thermometer gave notice that heating had reached a dangerous point, these valves could be opened, and the lower portion of the cargo drenched with salt water. This, evaporating rapidly, would give large volumes of water vapour, which, passing up through the heated coal, would lower its temperature, but would not be nearly as effective as the method before advocated. It might, however, be used in conjunction with that method, and would, in many cases, save the carbonic acid gas. The question of preventing the heating and ignition of stores of coal on land and ready for use in bunkers cannot be met so well by the use of the liquid gas, and, in these cases, it would be found beneficial to dress the coals with a little tar or tar oil, which would close the pores and, to a great extent, prevent oxidation. I believe this was advocated by Lachman about 1870. Crude petroleum in small quantities for this purpose would also be found valuable, for, as already shown, it has no tendency to oxidise itself, and lowers the tendency in other bodies, besides coating them, and so preventing access of oxygen.

The labour trouble in the coal trade is hampering all branches of industry, and, with increasing difficulty in obtaining coal, all sorts of rubbish will be shipped, and many a cargo of coal will go out during the next few months which, under normal conditions, would never have been allowed on board; and we may expect a heavy increase in the loss of life and property from spontaneous ignition. This will probably result in a rise in the rate of premium, and further check to our export coal trade; and I sincerely trust that, should these gloomy forebodings be fulfilled, the suggestions made in this paper, and based on experimental facts, may be found of value. In conclusion, I wish to acknowledge my indebtedness to the researches of Dr. Richters, whose papers on the weathering of coal are to found in *Dingler's Polytechnisches Journal* for 1870; to the report of the Royal Commissioners on this question in 1876; and, finally, to Mr. Martell for suggesting the subject of this paper.

In the discussion which followed, Dr. Elgar pointed out that, notwithstanding the great dangers arising from spontaneous combustion, it did not cause great losses. He argued that a fire which was generated in the centre of a cargo of coal took a considerable time to reach a point of danger to the ship. Meanwhile the ship could make for a port. As a fact, he had known fires to occur in the bunkers of large passenger steamers where thousands of tons were stored, and the passengers were in blissful ignorance of the dangers by which there were beset. He also drew attention to the American law, by which all ships had steam pipes running through their holds for the purpose of dealing with fires, and he thought the plan should be adopted through coal bunkers in order to furnish a means for coping with danger should any arise.

Mr. Parker said the subject had been brought before his notice by the Committee of Lloyd's Register, and he was requested to give his views. It was thought by steamship owners to be due largely to the higher steam temperatures in vogue in steamers and steam colliers.

Digitized by Google

He could corroborate Professor Lewes that this was not the case in what had come under his notice. The fires had always commenced in the centres of the bunkers, and not at the sides nor near the boilers, and so did not lead to the supposition that heat had led to the ignition. He had had ample opportunity of studying the matter, for one or two vessels came into the port of London every week with their bunkers on fire. He considered there were two distinct reasons for spontaneous combustion. It was well known that all coal was more or less contaminated with iron pyrites. The sulphur in the pyrites was liable to be slowly oxidised by the oxygen in the air mingled with the coal. Heat was generated by this oxidation, and the heat in turn promoted further oxidation. If sufficient air was present, the oxidation became more and more rapid, the temperature rose and the coal began to burn. Oxidation was promoted by moisture in the first instance, as the oxygen in the air was thus brought into more intimate contact with the sulphur. The precautions necessary were to keep the coals dry, to exclude air from penetrating the body of the coal, and to avoid the accumulation of small coal, which, by its fine division, multiplied the surfaces exposed to oxidation. The absorption of oxygen took place mostly when the coal was exposed to the air after being sent up from the pit. The more porous the coal, the more capable was it of taking up the air. With regard to the higher temperatures caused by the introduction of triple expansion engines, he had asked the officers of several steamers to obtain for him some figures bearing on the subject from their own observations. They agreed very closely with those given in the paper. He found where steam pressure was 80lb., a temperature of 324° Fahr. was developed, and the common stokehold temperature under those conditions was from 100° Fahr. to 130° Fahr. When the steam was 155lb., the temperature became 368° Fahr., or 44° higher than with 80lb., and there was a corresponding increase of temperature in the stokehold to 110° and 140° Fahr. He had written to the engineers of the principal steamship owners in the Kingdom, and the general answer was that the number of accidents arising from the cause stated was now less than when steam of 60lb. pressure was used.

Mr. McFarlane Gray said he had been asked by the Board of Trade some years ago to prepare a book of instructions upon the subject of spontaneous ignition. There was a doubt, however, whether it would be right to issue official instructions deprecating ventilation, and so nothing came of his work. He thought the appointment of an official chemist would be a good thing, as with shipowners and others interested in shipping many important questions appeared every day.

Mr. Eckersdale thought moisture was one cause of spontaneous combustion in coal, and the Admiralty rule was that no coal should be put on board during the wet season.

Mr. Stromeyer asked how the air could get to the centre of the cargo. He thought that it was absorbed during its passage from the pit's mouth to the ship's hold, for when a ship's hatches were battened down very little air could find its way through, say, 20ft. thick, to the centre, where ignition has usually been found to take place.

Professor Lewes then replied. He said that in wooden ships the spontaneous combustion was due to the difficulty in keeping the ships dry. There was no doubt that moisture made the coal crumble up, and so a larger surface was exposed to the action of the atmosphere. As regards the steam pipes used in American vessels through the bunkers, it must be remembered that English coal and American coal were not the same. These pipes were kept cold when not in use, and were of great service in extinguishing fires. He knew the abhorrence there was to all sorts of fiddling contrivances of all kinds, but he did not think if one of his apparatus were dropped in the cargo here and there any serious difficulties would be encountered. Referring to Mr. Parker's remarks, he said he was somewhat astonished when he knew that gentleman had drawn up a report bearing on this subject, but was relieved to know that it had not been published. It appeared that much the same results had been obtained practically as he had advanced from theoretical reasons. As regards his carbon-dioxide experiment, it was not intended to apply it in the case of a fire, though he had no doubt if it were placed in the centre of a large fire it would reduce that fire considerably. He thought it would be a poor fire that would burn 10° below the boiling point of water, yet so soon as the fuel had reached this heat the carbon-dioxide would be liberated; it would thus lower the temperature and cause a thin film of gas to surround the fuel and prevent combustion. Mr. Stromeyer had asked how the air managed to get at the centre of the coal, and how it happened that it took in gas instead of giving out gas when heated. There were several matters connected with the occlusion of gas which were very interesting indeed. He had shown them how a piece of charcoal would absorb many times its own volume of oxygen. In the same way the coal absorbed the oxygen present in the small interstices between the separate particles forming the heap of coal. They should therefore batten down their hatches in order to exclude the air.

Mr. J. Corbett then read a paper on "Experiments with Lifeboat Models." The author has been engaged for many years in experiments on models to ascertain the best forms of lifeboat, and these experiments were renewed after the failure of the Southport lifeboat in 1886. We summarise the recommendations contained in Mr. Corbett's paper in the following paragraphs:—

Form of Side and Gunwale.—It is usually the blow of a sea on the upper part of the side that does most injury; it is therefore desirable to keep the sides as low as practicable. Low sides are also less distant in height above the centre of gravity of the boat. The blow of a sea broadside on, when it cannot be avoided or reduced, may be evaded by means of sloping or "tumble-home" sides to the boat.

Relative Form of Bow and Stern.—If the boat be sailing or rowing to windward against a heavy sea, the bow must be comparatively fine in form to reduce the shock of each wave. It must have a considerable surplus of buoyancy so as to rise to each wave, but must not have such an excess of buoyancy or of horizontal area as would raise it high above the wave, thereby losing way and giving the wave a chance of turning the boat end over end. The bow should be decked over for some length, so as to permit of running into a wave and rising through it without taking much water on board. The stern has altogether different duties when the boat is going to windward. Any reasonably fair form will enable the water to close in the boat's wake without undue drag. Full quarters would so extend the water-plane area as to offer a valuable resistance to depression when the bow is rising to a wave, thereby maintaining headway, and preventing the boat's rising on end; and this can be effected with comparatively little surplus buoyancy at the stern. The rudder power would be increased by comparatively fine lower lines below the full quarters. Stability for sailing, or to resist capsizing, would be greatly increased by thus continuing the breadth further aft; and in every way it appears that for going to windward a fine and moderately high bow, and a broad and comparatively low stern, and fairly deep keel and rudder, would best give the qualities required.

For running free the very same qualities are required, with the additional consideration that the bow must not have too lofty a side, since the blow of a sea on one side of the bow has been one of the causes of capsizing. If the gunwale amidships can be kept low, or made of a tumble-home form, it will further help to reduce the blow of a sea.

In running before the sea, and especially in landing through heavy breakers, somewhat opposite conditions are met with, but none which would render it desirable to take such a lifeboat in stern foremost. The great desiderata here are, that the bow end shall have ample buoyancy to prevent its burying when a wave overruns the stern; and that the stern shall have a deep grip of the water, and comparatively low sides, to prevent its being turned aside by the blow of a sea on one quarter, the most frequent cause of broaching to and capsizing. Being overtaken and pooped by a following sea, the direst peril of an open boat running through breakers is comparatively harmless to a lifeboat whose buoyancy depends on air-cases: and therefore a low stern with somewhat deep keel, and a high bow with considerable surplus of buoyancy, will best meet the requirements.

Thus, whether rowing or sailing to windward, running free, or running before the sea, a fine bow with considerable surplus of buoyancy, and a broad stern with but a moderate surplus of buoyancy, seem the safest and best for lifeboat work.

Curves of Sectional Areas.—A number of diagrams of the curves of various boats were given. One of the many detriments involved in the self-righting system is the possession of angular lines of sectional areas above water.

Proportions of Weight to End Area.—The total end area of a boat, in comparison with its weight, is almost a criterion of its power of facing rough water, since impetus is essential to holding the boat's way when meeting a sea.

Towing Resistance against Head Wind and Sea.—When going to windward, just as much resistance is caused by the above-water surfaces, which meet the flying spray and broken water, as that caused by the immersed parts, which are in less disturbed water. Also fineness of form, and absence of flat or blunt ends, either above or below water, tends to easy progress to windward.

Curves of Stability.—The author has also found the curves of stability of the various types of boat.

Self-Righting Powers.—The officers of the Lifeboat Institution have recently effected a great increase in the entire self-righting power of their boats, by the enlargement of the end air-cases, greater rise of floor amidship, the addition of two inches depth of keel, and the reduced beam in the lifeboat of 1887 as compared with that of 1862. But this increased righting power when capsized is obtained by sacrificing one-fifth of the stability when not capsized; and it is quite evident that the common statement, that the features which give the self-righting power also increase the stability of a lifeboat, is utterly erroneous and misleading. It appears certain that the frequent disastrous capsizes of the small rowing lifeboats might be almost always prevented by giving them considerably more stability. It is possible by heavy ballasting, and by a modification of the usual proportions of the boat, without any increase of draught, or of weight when on shore, to provide a lifeboat with fully twofold greater stability, and with threefold more resistance to capsizing by a sea, than a self-righting boat has; and the author thinks that this greater stability, with better rowing and sailing qualities, would compensate for the absence of the self-righting quality.

The Side-Decked Lifeboat.—The author then described an attempt to embody in one design many of the good features of the five existing types of boat. This boat is 34ft. length over all, and 8ft. 9in. beam, rowing ten oars; its most peculiar feature is side-decks, or tumble-home sides, whichever they may be called, at about 45° angle from the gunwale to the low fenders. These, together with the deep sides of the hull, give a lateral stability at load draught 160 per cent. greater than the approved rowing self-righting boat. The sloping sides give little hold to a sea striking the broadside. The rowlocks, placed on a gunwale of 7ft. 6in. beam, like an ordinary lifeboat, will heel much less than rowlocks at the full breadth of the boat. The low but unusually low bow air-case is intended to give an easy lift in entering a wave; while the full stern steadies the boat, and prevents the bow from hammering unduly over short waves, or rising on end against a high breaker. The narrowed bow end of the working space tends to keep out water when heeling over. The slight coamings at bow and stern and on the gunwales are shaped to give a good hand grip. The end outline area is rather less than that of the self-righting boat, though the total bulk is 1·6 tons more. The displacement is 1·4 tons more than that of the self-righting boat, and this would be utilised for water ballast, so as to increase the stability and momentum of the boat without adding to its weight when on shore. By thus adding 1·4 tons of ballast to the boat, its great water-plane and plan-outline areas are more heavily weighted per square foot than the rowing self-righting boat. The lateral outline area is one-tenth less than the self-righting boat, and, having much less vertical side, the boat would be able, by this and its stability together, to resist much more of a wave blow than would capsize the self-righting boat. The weight per square foot of end area, being one-third more than that of the self-righting boat, would give great impetus for resisting a breaker or sea. Its towing resistance is the same as the self-righting boat, and as its sail-carrying power is 160 per cent. greater, its comparative power of sailing to windward is 160 per cent. greater than the self-righting boat. The horizontal square tube or casing within the bow air-case, and the opening in the second thwart, provide for easily stowing the masts below the thwarts, and so leaving working room for longer oars. The large recess in the boat's floor and the ball valves and canvas curtain ensure a rapid discharge of any water coming on board. A drop-keel of short length would be fitted, but even without this valuable appliance the boat would be well able to beat to windward, from having a deeper keel and lower end air-cases than usual. By omitting two of the usual three battens over the side air-cases, these cases are raised 2in. without raising the seat height; and the thwarts are also raised to the rowers' seat height, omitting the usual raised seats. The side air-cases above deck are of 104 cubic feet, or just double the bulk of those in the ordinary lifeboats, include in this cube the cork filling up to the side decks and gunwales.

The last paper was by Mr. James Howden, on "Various Theories of the Screw Propeller." Mr. Howden is well known as an expert in the design and construction of screw propellers, and also as an opponent of the generally accepted theory of propellers which was propounded by Rankine and further elaborated by Greenhill, Froude, and Cotterill. Former papers read before various societies by Mr. Howden have been ineffectual in dislodging Rankine's theory from its position, and the alternative theory contained in them has been all but forgotten. The object of the present paper was to resuscitate the discussion on the merits of the two conflicting theories. As the paper was chiefly a reiteration of former statements and arguments we think it unnecessary to reprint it here. The discussion was without interest.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 22nd April, 1890.

Iron.—The iron market here has changed but little in the course of the last week. Business is slack and without immediate prospect of improvement. Prices remain nominally at 152s. for bars, and 156s. for joists; but terms are offered which practically makes the latter 154s. Some slight changes have occurred in the provincial centres of the iron trade. Thus there is less activity in the Haute Marne, and the improvement which appeared last week in the markets of the Nord has been lost. On the other hand the export trade in pig iron from the Meurthe-et-Moselle has increased, and more favourable reports are to hand from the Ardennes. The galvanising industry is about to be founded in the latter locality at Sedan.

Coal.—The scarcity of coal continues to favour the import trade, which has more than recovered the loss it sustained last year. The quantity of foreign coal received and delivered for consumption in France in the first three months of the current year amounted to 2,080,794 tons, against 1,875,128 tons in the corresponding period of 1889, and 1,974,715 tons in 1888. Of this quantity England furnished 1,047,157 (895,438) tons; Belgium, 880,211 (816,863) tons; and Germany, 150,786 (162,566) tons, the figures in parentheses being those for last year. The imports of coke amounted to 291,834 tons, against 161,115 tons in 1889. The whole of this increase is in the trade with Belgium.

Metals.—Business in the metal markets continues to shrink, and prices follow a downward course. Copper quotations show but little change from those of last week, but the tone of the market is weaker. The same remark applies to the market for tin. Lead has given way considerably. The present quotation is £13 5s. for Paris. Spelter, too, is steadily declining. Silesian is quoted £22 16s. at Havre. Consumers are now buying in very small quantities, sufficient only for the requirements of the moment, which are not large.

Trade with Portugal.—With a view to enable his countrymen to profit by the ill feeling against England now existing in Portugal, M. Dejante, a member of the Council of the French Chamber of Commerce at Lisbon, has prepared from official statistics a set of tables and classified lists showing the imports from the five great producing countries of Europe, copies of which have been sent to all the Chambers of Commerce in France as well as to a large number of individuals. These documents indicate where trade hitherto in the hands of the English may be diverted in favour of French industry.

French Railways in 1888.—Recently published returns show the results of the working of the six principal lines of railways in France during 1888. It seems rather strange that they should be more than a year behind date, but that is the way with things here. The lines of which particulars are given are those of the Compagnies du Nord, de l'Est, de l'Ouest, d'Orléans, de Paris-Lyon-Méditerranée, and du Midi respectively. The total capital raised by the six companies up to December 31st, 1888, amounted to 11,903 million francs, of which 11,711 millions had been actually expended. The total mileage authorised to be constructed was 35,852 kilometres, while that open for traffic was 29,529. The cost of construction, including rolling stock, amounted to 386,708 francs. Deducting the cost of the rolling stock, the cost of the permanent way in pounds sterling was very nearly £18,000 per mile, which is very high. The total receipts of the six principal lines in 1888 for an average mileage open to traffic of 29,144 kilometres was 1,005,523,210 francs, the total expenditure amounted to 502,661,436 francs; the net receipts were consequently 502,861,774 francs, and the proportion of the expenditure to receipts was 49·99 per cent., compared with 50·53 per cent. in the preceding year. The expenditure was increased in 1888 by 0·78 per cent., against an increase of 1·74 per cent. in the receipts, and an augmentation of the mileage open for traffic of 1·06 per cent.

BERLIN, 21st April, 1890.

Iron.—The business of the iron market has been visibly affected by the result of the tendering for locomotive coal at Magdeburg and Elberfeld. Buyers see in the event a near prospect of cheaper fuel, and, consequently, of cheaper iron, and they manifest a disposition to delay the placing of fresh orders. On the other hand, sellers are more desirous of booking fresh orders at the current rates, and offers are made of conditions which amount to slight concessions on those rates. The Breslau merchants have even reduced their prices for rolled iron 10s. a ton, making the latest quotation for bars 210s.

Coal.—The event of the last week has been the tendering for the locomotive coal required during the ensuing year for the Magdeburg and Elberfeld railways. The lowest offers were 13s. 6d. a ton in the former case and 12s. in the latter. These prices are so much below the current rates that the whole of the industrial world of Germany has been thrown into a state of commotion, the obvious inference being that the colliery owners expect much lower rates for coal before the end of the year. From Upper Silesia we learn that though the demand for house coal is now rapidly falling off prices are firmly maintained. But it appears that this firmness is due to the prospect of labour difficulties, for we are told that in several places the miners have come out on strike for the eight hours shift. There is no prospect of this demand being granted, but the refusal may lead to some conflict. A number of deep-earth borings are now in progress for the purpose of further developing the coal-fields of Upper Silesia. One of these has been brought to a stand by a strike for higher wages; another has just reached a thick seam of the coal.

Metals.—Business in the metal markets continues to decline. Transactions are few and of little importance. Consumers buy only sufficient to cover the most pressing needs of the moment, the general belief being that prices will go lower. Copper has receded a little, Mansfeld refined being now quoted £58 10s. to £60, and English brands from £55 10s. to £57. Tin is very weak at £97 10s. to £98 for Banca. Lead continues firm; but zinc has further declined. Silesian W.H. spelter is quoted £23 15s. Berlin zinc dust is in demand, but zinc white is neglected. Antimony regulus is a little cheaper.

India-rubber Goods.—At a meeting of the convention of German manufacturers of india-rubber goods, held the other day at Hanover, it was resolved to advance the prices of their produce from 10 to 20 per cent., to cover the increased cost of the raw materials. The quantity of india-rubber and gutta-percha in the unmanufactured state imported into Germany in the first two months of the current year amounted to 11,982 cwt., against 11,034 cwt. in the same period of 1889. The exports of manufactured rubber and gutta-percha goods in the same periods amounted to 2,224 cwt., against 1,856 cwt.

Railway Rolling Stock.—Never has there been greater activity in the production of railway rolling stock than now. The locomotive shops are gorged with work, and the makers of goods waggons are scarcely able to meet the demands made upon them. Within the last week some of our locomotive builders have been asked to tender for a number of engines required for one of the Russian lines.

An Electric Railway for Russia.—It is proposed to have an electric railway to connect St. Petersburg with Archangel, and to span a wide stretch of country between the Baltic and the White Sea. The project is backed by Archangel interests, and the name of Siemens & Co. is connected with the enterprise. The plan is to furnish the current from a series of generating stations distributed along the line. The distance is over 500 miles, and the estimated cost a little over £3,000 per mile, including rolling stock. The scheme is a daring one, and its progress will be awaited with interest by the advocates of electric traction.

Steamers to East Africa.—A company has been formed at Hamburg for the establishment of a German line of steamers to East Africa with a capital of 6,000,000 marks, of which 25 per cent. has already been paid up.

VIENNA, 21st April, 1890.

The Iron Market.—In well-informed spheres it is felt that some change is visible in the position of the market. Works still have many orders on hand, but new ones do not seem to come in so fast as hitherto. The prospect of new increases in prices has now disappeared, and dealers and consumers are waiting for a crisis. As I reported last week, the locomotive manufactory of Wiener-Neustadt received an order from the Saxony State railways for eleven locomotives. Messrs. Kraup & Co. of München, Sachsische Maschinen-fabrik of Chemnitz, Messrs. Schwarzkopf of Berlin, and Hentschel & Sohn of Cassel tendered for the order also, but the firm of Sigl & Co. obtained all the orders that did not go to Wiener-Neustadt, because their term for delivery was the shortest. Another order is to be given by the Dux-Bodenbach Railway for four locomotives at a price of 152,000fl., and a sum of 282,950fl. has been set apart by the same railway company for the construction of 123 coal waggons. A good business is being done in agricultural machines. The Budapest agents of Messrs. Ruston, Proctor, & Co., of Lincoln, have delivered some machines in Vienna for electrical purposes.

The Coal Market.—The situation of the coal market continues very firm, and prices are steadily increasing. The prices of some sorts are also kept high by the insecurity caused by the labour question. The Silesian works are threatened by strikes, and at Ostrau the labourers have already ceased to work. The Vienna supplies will now have to be procured in greater quantities from Bohemia. Already the Bohemian collieries have hard work to answer the demand. The Brüxer Kohlenbergbau-Gesellschaft has bought two new pits near Dux, and in order to work them it is increasing its capital by 10,000 shares of 100fl. This company pays this year a dividend of 7 per cent., against 6½ per cent. last year.

Gas Lighting in Austria.—The other day the Gas Company of Vienna held its annual meeting. During the past year it has made a clear profit of 549,000 florins on a capital of 4,000,000 florins, and a dividend of 9½ per cent was declared. The remainder went to swell the reserve fund, which, however, for all practical purposes, has been quite large enough hitherto. By many this constant addition to capital is considered highly injudicious. This gas company owns a large number of installations in other towns of the empire besides Vienna—*e.g.*, Fiume, Pressburg, Graz, Brünn, and Temesvar.

Transmission of Power by Compressed Air.—The scheme for the establishment of a central station for the distribution of power by means of compressed air is now taking a defininite shape, and a suitable site has been acquired for the erection of the buildings and machinery.

The Wood Wool Industry.—The demand for wood wool is very animated at present, and it is generally hoped that the market for this commodity will now be able to throw off the sluggishness which has characterised it lately. The last business year has not been particularly satisfactory, and only one works—viz., the Felixdorf—could show a large balance at the stocktaking.

The Zone Railway Tariffs.—The latest Hungarian railway returns show that, during the period from 1st of August, 1889, to 31st of March, 1890, the traffic on the State railways amounted to 7,770,876 passengers, against 2,891,332 in the corresponding period before the introduction of the zone tariffs, which is an increase of 169 per cent. The result is still more remarkable with regard to the traffic between neighbouring stations. Whereas under the old tariffs, in 1877, only 255,000 persons used the railway for such short journeys, their number during the above-mentioned eight months rose to 4,367,586. It is reported here that the Hungarian Government are contemplating a further reduction of passenger fares, especially with a view of transferring the great summer traffic from the Austrian Alps to the Carpathians.

BRUSSELS, 22nd April, 1890.

The Iron Market.—The position of the iron market is becoming more and more serious. The price of coal is likely to retain its high level, and pig iron makers find it perfectly impossible to make any abatement in their quotations. The consequence is that trade is very much narrowed and orders are difficult to execute. One of the ironworks, that of which M. F. Bailly is head, has obtained a large order for material for Portugal, and M. Bailly has received the distinction of the Cross of the Order of Christ. There is also a large order for locomotives for Russia on the point of settlement. The prices at present are stationary, on account of the impossibility of business. They are compared with the prices during April, 1889, in the following table:—

	1889.		1890.
Grey pig	45·95fr.	...	48·55fr.
Forge pig	52·93fr.	...	59·41fr.
Bessemer pig	58·86fr.	...	66·17fr.
Joists and large bars	113·92fr.	...	121·72fr.
Small bars	118·05fr.	...	132·90fr.
Angles	124·03fr.	...	131·98fr.
Sheets	146·38fr.	...	160·33fr.
Steel rails	105·62fr.	...	108·89fr.

The Glass Trade.—No particular feature has distinguished the trade of the past week. There are not sufficient orders to keep pace with the production, and the production will therefore have to be reduced. The continued steadiness of the prices of coal has damped all hopes of a cheaper production of glass. Several good orders have come to hand from the United States, but England is asking for very little at present. The exports of window glass during the first two months of the present year amounted to 13,280 tons, as compared with 14,891 tons during the corresponding period of 1889.

The Coal Market.—Ever since the last adjudications of the contracts for the supply of coal for the State railways the prices have remained very firm, and the present position of the market seems to be impregnable. The exports and imports of the first two months of 1889 and 1890 are compared in the following table:—

	Tons. 1889.		Tons 1890.
Coal imported	170,612	...	324,871
„ exported	599,739	...	666,514
Coke imported	3,323	...	5,176
„ exported	187,398	...	221,192
Briquettes imported	—	...	—
„ exported	44,678	...	40,502

The number of trucks employed on the State railways for goods traffic during the past week is compared in the following table with the number during the similar week last year:—

	1889.		1890.
Coal and coke	18,731	...	21,673
Other merchandise	34,669	...	34,993
Other fuel	3,248	..	2,586

DÜSSELDORF, 22nd April, 1890.

Iron.—The declining tendency of the iron market in this locality has become more distinctly marked since it became known that the recent tendering for locomotive coal opened up a prospect of lower prices for fuel. Buyers now will not go beyond present requirements, and even in these transactions they manifest a disposition to stand out for some concession in prices. Business in pig iron is very slack. With the exception of foundry pig, however, which has receded two or three shillings a ton, prices are scarcely altered from what they were a week ago. But the offers of foreign pig which are being made at greatly reduced rates cannot fail to bring down in a little time the syndicate minimum for German pig. The current quotations are: Ordinary spiegel pig, 102s.; Rhenish-Westphalian forge, 89s. to 90s.; Siegen forge, 89s.; foundry pig No. 1, 95s.; Thomas pig, 78s. to 80s.; and Bessemer, 93s. to 94s. a ton. Business in finished iron and steel is fairly active; but it

Digitized by Google

is wanting in that life and vigour which characterised it a few weeks ago. The merchants are making considerable concessions in prices.

COAL.—The relatively low prices tendered for the Magdeburg and Elberfeld railway contracts for locomotive coal, the deliveries of which are distributed over the next twelve months, have greatly disturbed the markets. It is evident from these tenders that the colliery owners have begun to realise the necessity for cheaper fuel, and that they have convinced themselves that the present rates cannot be much longer maintained. Buyers are, in consequence, disposed to press for immediate concessions, and sellers are showing themselves more willing to discuss terms with their customers. It is now pretty certain that no general strike will take place this year.

ENGINEERS' VISIT TO THE UNITED STATES.—The invitation of the American Institute of Mining Engineers to the Vereindeutscher Eisenhüttenleute, an association similar in character to the English Iron and Steel Institute, has been accepted, and it is now certain that a large number of the members will visit the United States next autumn. Already upwards of eighty have signified their intention to be of the party. The latter will leave about the 22nd of September, and the visit will be of four weeks' duration.

LILLE, 22ND APRIL, 1890.

IRON.—The increased demand of last week has died out, and the market is again languid. The slackness of business in Paris has a most depressing effect here, for the capital is our most important market. For the present manufacturers have plenty of work on old contracts, but, fresh orders being scarce, they have cause for anxiety. Prices are maintained with some firmness, but with falling markets abroad and shrinking business at home the prospect is not encouraging to sellers. It is not to be wondered at that in such circumstances consumers abstain from buying beyond the needs of the moment.

TEXTILE MANUFACTURES.—The busy period in the linen goods trade is now past, but though the current of business is gradually slackening, it still keeps above the average strength for this time of the year. The situation must, therefore, be considered satisfactory. There are fewer buying agents to be seen now at Armentières, but orders continue to come to hand freely through the post. The export trade is fairly active. The Customs' returns for the first three months of the year show the declared value of the exports to have been £105,840 for linen and hempen piece goods, and £115,840 for flax and hemp yarns, against £73,600 and £108,320 respectively.

FLAX AND YARNS.—The demand continues strong for home-grown flax, and as the quantity on offer is not large, prices are easily maintained, especially for the better sorts. Business is somewhat less active in Russian produce. Tows of good quality are inquired for, but there is not much doing in the middling and the lower qualities. Jute yarns are in strong demand. For linen yarns the market is more active, and prices are very firm at last week's quotations. The declared value of the raw flax imported in the first three months of the year amounted to £780,520, against £933,400 in the corresponding period of 1889.

AMSTERDAM, 21ST APRIL, 1890.

THE ROYAL MACHINERY FACTORY AT AMSTERDAM.—This factory, which has been forced into liquidation by an unfortunate combination of circumstances, has discharged some 200 artisans. It is hoped no more need be sent away at present if the Government contracts with the company are kept up.

THE GOLDFIELDS OF GUIANA.—It is understood that the Dutch Government has withdrawn its reserves regarding the subject of the delimitation of the extent of the goldfields in Guiana which is in dispute. The Emperor had declined the proffered arbitration of the rival claims of Holland and France, owing to Holland's reserves. These having been withdrawn, the Czar has consented to act.

STEAMBOAT COMPANIES.—The Steamship Company "Nederland" (Amsterdam-Batavia) is enabled to distribute a dividend of 10 per cent. to its shareholders on account of the operations in the past year. The directors of the Netherlands American Steamship Company state in their report that the results of the trips to the Argentine Republic have not been so profitable in 1889 as those to the United States, but, on the whole, the operations of the company have been very satisfactory. The directors, however, opine that 1889 has been an exceptionally busy year, and they doubt very much whether 1890 will show an equally brilliant result—17 per cent. dividend—the less so because the capital of the company has been doubled lately, and the new ships are not yet completed.

RAILWAYS AND TRAMWAYS.—The sections of the Second Chamber have issued a rather unfavourable report on the Government proposals regarding the State purchase of the Dutch-Rhenish Railway and the conventions with the State Railways and Holland Railway Companies. The majority doubts the wisdom of the Government proposed system, and thinks the price paid to the Dutch-Rhenish shareholders too high. Meanwhile the various conditional conventions have virtually lapsed, and the shareholders of the different companies have been convened afresh to sanction a short postponement of the dates of ratification pending the passing of the Government Bills in the two Chambers. The Dutch District Railways and Tramways Union held its annual meeting last week. Various points of mutual interest were discussed, among others new modes of heating carriages and obtaining cheaper fuel for motive power.

DRAINAGE IN FRIESLAND.—A drainage syndicate has been formed in Friesland to drain the low-lying lands which separate the mainland from the North Sea islands. It requires, however, a Government subsidy of 4 per cent on a capital of £1,000,000 for six years, and a further payment or grant for each acre of land laid dry. In answer to a request to that effect which the syndicate forwarded to the Government, the latter has replied that it could not ask the sanction of the States-General on the plans as made. An inquiry by experts, said the official reply, had shown that the proposed drainage of the indicated lands would not have necessarily the anticipated results. Moreover, the financial proposals were not of a nature to be taken into consideration. But if others, less onerous, were propounded, the Government would examine them with a view to acceptance.

COALS IN BORNEO.—The Dutch East Borneo Coal Company has received favourable advices from its collieries, and the developments of the mines at Kutei are better than the directors anticipated. Under these circumstances the shareholders have resolved to increase the capital of the company by a further issue of shares, which have already been taken up at a premium.

COPENHAGEN, 19TH APRIL, 1890

A LARGE SWEDISH CONCERN.—Large manufacturing establishments, with several distinct departments and vast estates, are not uncommon in Sweden, but none can probably vie with the Ljusne-Voxne Company, Sweden, of which a few particulars will no doubt be of interest. The beginning was modest enough, when thirty or forty years ago Mr. Wilhelm H. Kempe, from Stockholm, commenced business on the coast near where the Ljusne river runs into the sea. The Ljusne harbour can now accommodate steamers of 2,000 tons. The two principal articles of export are timber and iron. The export of timber, which is the most important one, amounts to about 30,000 standards every year. The company owns some very extensive forests in Dalarne. The flooding of the timber takes place down the Ljusne river, and is under the control of a special "flooding manager." It was a difficult undertaking, in the first instance, to regulate this transport by water, and for the first couple of years the greater portion was lost in the sea. The saw mills are on a very large scale, working day and night; the timber is dragged from the river by iron chains. With regard to the iron industry, the development has been gradual but steady, and continuous blast furnaces were erected in the year 1873, engineering works in 1876, and rolling mills in 1883. In the year 1886 the company bought South Ljusne Ironworks, the concession of which dates as far back as 1671. The North and South Ljusne Ironworks now comprise three blast furnaces, fifteen forges, and fourteen rolling mills, which are all worked by water taken through canals from the Ljusne river. The manufacture of pig iron amounts to some 300,000 cwt. annually, and this is afterwards further handled at the establishment for export. The company has its own mines as well as its own forests. The number of people attached to the Ljusne establishments is about 4,000, and the wages are generally very good, so there have been no strikes.

MADRID, 21ST APRIL, 1890.

FIRE AT THE MADRID GAS WORKS.—A fire, which has lasted more than twenty-four hours, broke out in the gas works of Madrid, on the 14th inst. This accident was very serious, and caused an interruption in the gas supply, which was, however, only temporary.

PAPER MILLS.—No sooner has a company, at the head of which are some of the partners of the rich house of Messrs. Ibarra, decided to establish a first-rate paper mill, than other parties are following in the same track, and in the course of the present year Biscay will possess two paper mills, which will include every recent improvement.

IMPROVEMENTS IN BILBAO.—This town is being continually improved by the wealth which the iron ore mines are putting in the hands of every class. At this moment a very large and luxurious hotel is being erected in connection with the railway station. The electric station of the Electric Company is in an advanced state, and will be ready to commence service by the end of May.

MINING MOVEMENTS AT BILBAO.—Business in mines is in a flourishing state. A company with a capital of £600,000 is to be floated to work the Parcocha mine, which is supposed to contain a large quantity of ore of the excellent but now scarce Campanil variety. Another mine, only six hectares in extent, is reported to have been sold for £170,000, and an unexplored claim has brought £20,000 cash.

THE RAILWAY MANIA IN BISCAY.—The railway mania prevailing in this province is greater than was imagined at first, and in a few months from now every line of any kind that can be reasonably constructed will be taken up and carried out. The shares of the Bilbao and Portugalete Railway are sold at 268 per cent. premium, and many holders will not sell under 400 per cent. This is anything but unreasonable, it being a fact that, though their fares are very low, 14 per cent. is earned.

NEW YORK, 12TH APRIL, 1890.

THE IRON TRADE.—There has been something of an improvement in the iron market, although prices still remain low. The demand is rather better in almost all lines. In pig iron prices about hold their own. Some outside brands are being offered at very low figures, but little business is done in them. Production is still very heavy, and is likely to continue so, unless there is a serious drop in prices, and consumption must be well kept up if prices are to remain at their present level. Manufactured iron is more active, and although prices are yet unchanged, the increased demand will in a short time, if maintained, start them upwards again. There is considerable demand for bars from car-builders, and plates are a little higher. There is more inquiry for steel rails, but prices barely hold their own. Slabs and billets are lower, and the decline in prices has made orders for rails more desirable.

THE COAL TRADE.—There has been little change in anthracite. Prices are about the same, and cutting is confined to white-ash coals and odd cargoes generally. There is more inquiry for future delivery, and the leading operators unite in refusing to make any contracts for delivery ahead at anything like present rates. The Delaware, Luckawanna, and Western Railroad Company has announced to shippers that it would hereafter charge as freight on coal 50 per cent. of the net f.o.b. selling price at tide. This is equivalent to a reduction in freight rates of about 20 per cent. per ton. This new departure will force the other carrying companies to reduce their rates. The taking of such a step without consulting the other companies does not promise well for the continuation of the present combination. The H. C. Frick Coke Company have closed down 676 ovens indefinitely because of the lack of orders. The labour leaders say that there is a probability that all the works in the region will be put out of blast owing to the great dissatisfaction it is causing among labourers.

BESSEMER STEEL WORKS.—The West Superior Iron and Steel Company, of West Superior, Wisconsin, have decided to construct a Bessemer steel plant for the manufacture of steel plates and other iron and steel work.

THE LATEST AMERICAN SYNDICATE.—Syndicates are extending in every direction in America, and now every important industry is more or less under their control. One has lately been formed to obtain control of all the lithographing business throughout the country. The capital at the back of this big venture is stated to be $200,000,000.

THE "PLYMOUTH."—The third large side-wheel steamboat, built at Roach's ship yard for the Old Colony Steamboat Company, was launched last week. She has a double hull, and is built of steel on the bracket plate longitudinal system, with seven watertight bulkheads and fifty watertight compartments. Her engines will be of the four-cylinder triple-expansion type of 5,000 horse-power. There are 250 state-rooms, and there is accommodation for 1,200 passengers.

THE NORTH RIVER TUNNEL.—A serious accident has occurred at the New York end of the North River Tunnel, which has been in process of construction for the last fifteen months. At the foot of the shaft on the New York side is a caisson 48ft. by 23ft., having its roof 35ft. below the top of the shaft. From this caisson the tunnel has been carried 150ft. under the river. On Sunday morning last a workman searching for possible leaks between the timbers in the roof of the caisson set fire to the oakum with which it is caulked. The shaft was flooded to prevent the fire destroying the caisson, since which time it has been impossible to clear the caisson of water. From the New Jersey end the tunnel has been carried 2,000ft. under the river. The flooding will cause considerable loss of time and money, and may necessitate the securing of a new terminus on the New York side of the river.

SOUTH PENNSYLVANIA RAILROAD.—Numerous efforts have been made to revive this road, but none have so far been successful, and a short time since it was sold. The purchase was probably in the interest of the Reading Railroad. For a long time the Reading Road has been seeking an outlet to the West. At present all its south-western business ends at Harrisburg, and has to be transferred to the Pennsylvanian road at that point The Reading is now building a new line from Harrisburg to Bowmansdale, and it would cost very little to connect with the South Pennsylvania. The road is partly graded, most of the tunnels are built, and a number of bridges are up, so that it would require a small amount of money to finish the road. Its completion would be of great service to the Reading Company.

HUDSON RIVER BRIDGE.—The House of Representatives has passed a Bill authorising the construction of a bridge from New York City across the Hudson River. The bridge is not to have less than six railroad tracks, with a capacity of four additional tracks for future enlargement. It is to be constructed with a single span between the towers located between the shore and the established pier head lines in either State. It is to be as high above the water in the clear as the present Brooklyn Bridge, and no pier or other obstruction, either temporary or permanent, is to be erected between the towers. The construction is to be begun within three years, and it is not to take over ten years in building. The plans are to be approved by the Secretary of War. The company is authorised to issue bonds secured by mortgage on its property. All railroad and telegraph companies are to be entitled to equal rights in using the bridge for a reasonable compensation to be approved by the Inter-state Commerce Commission.

DIRECT ACTING HYDRAULIC PUMPING ENGINE.

CONSTRUCTED BY MESSRS. KNIGHT & CO., ENGINEERS, SUTTER CREEK, CALIFORNIA.

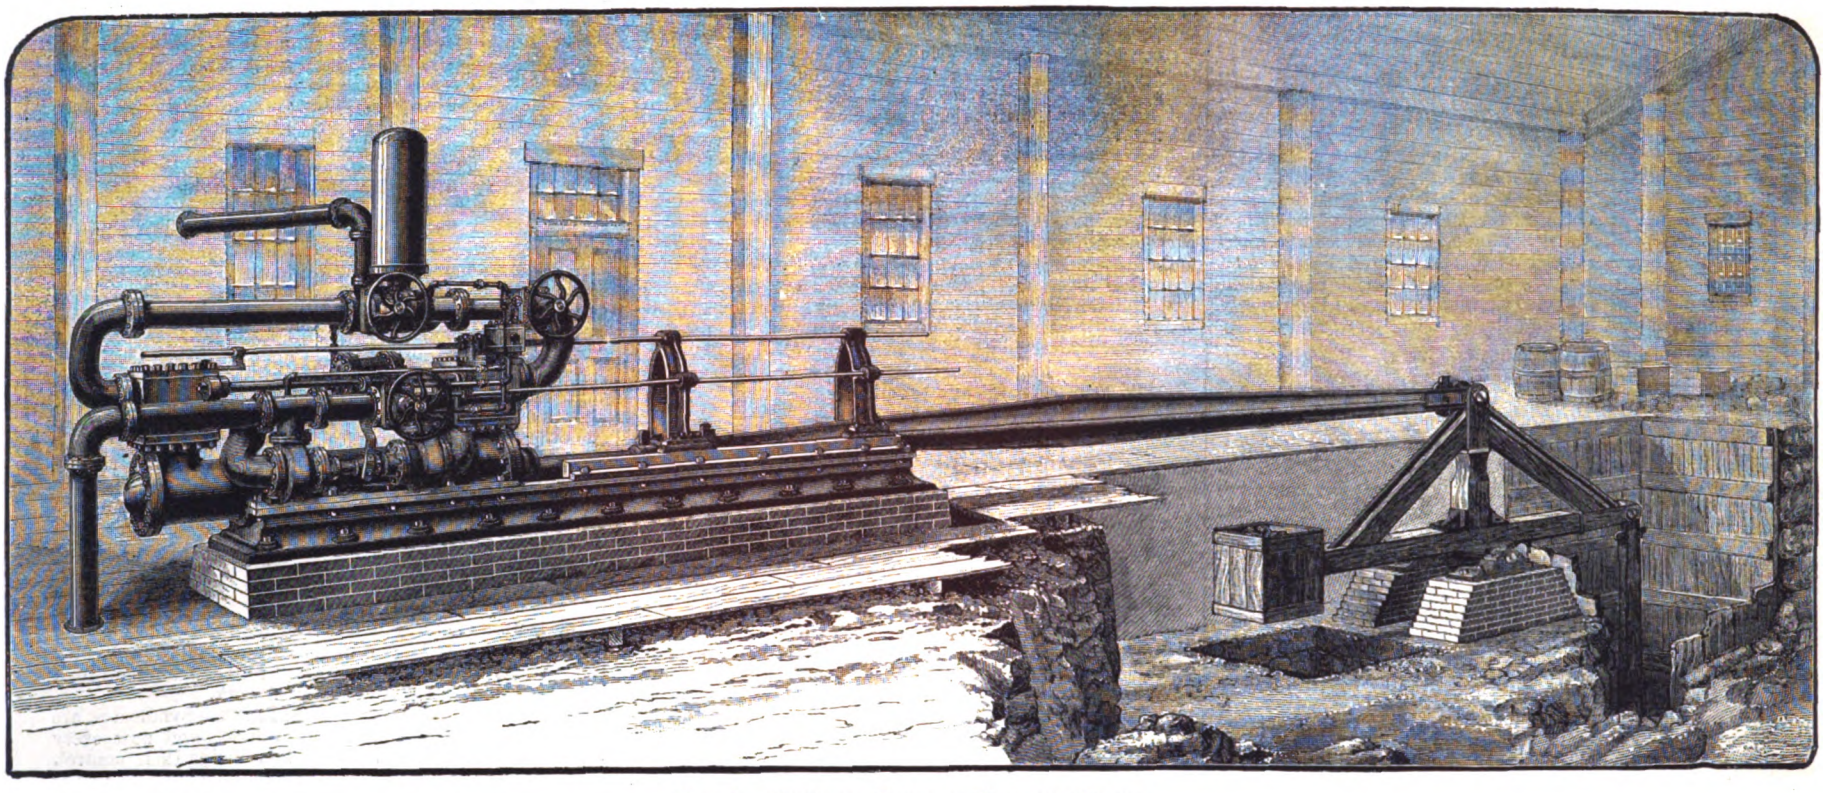

FIG. 1.—GENERAL VIEW OF PUMPING PLANT.

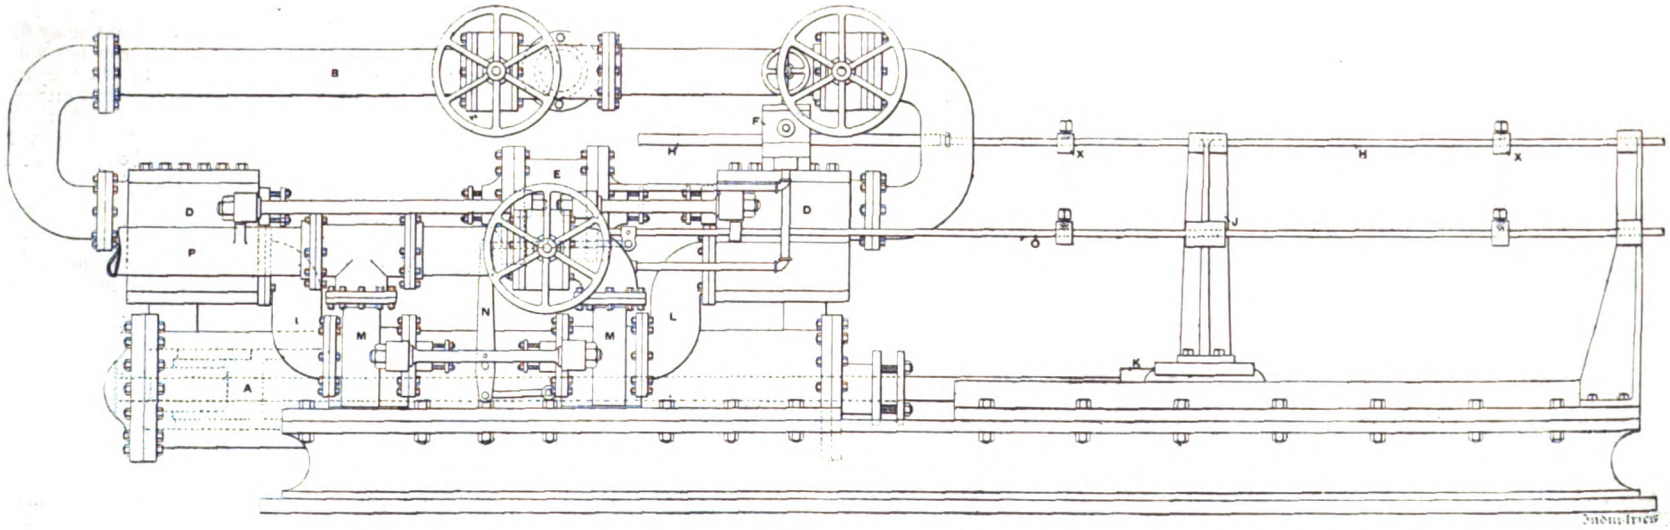

FIG. 2.—SIDE ELEVATION OF PUMP.

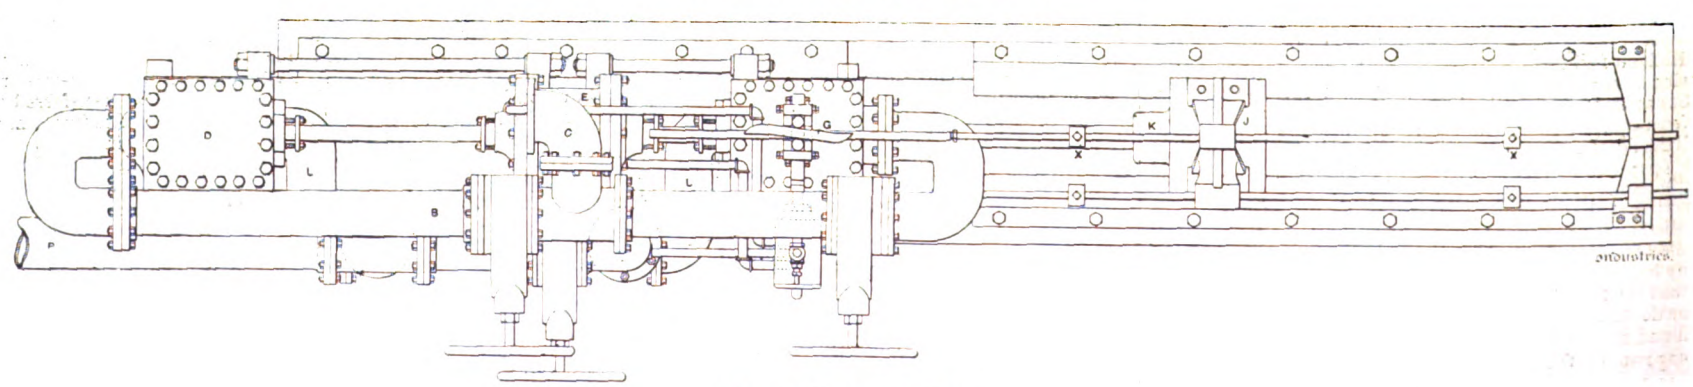

FIG. 3.—PLAN OF PUMP.

DIRECT ACTING HYDRAULIC PUMPING ENGINE.

WE illustrate above a type of direct acting pump which is designed to be driven by water pressure having "heads" from 300ft. to 500ft., or even 1,000ft. The pump has been designed and constructed by Messrs. Knight & Co., engineers, Sutter Creek, Amador County, California, and the credit of its gradual evolution is mostly due to Mr. Samuel Knight, who has devoted many years to the application of high-pressure water power to mining operations.

The main cylinder is 12in. diameter, and is of wrought iron, and the side pipes are steel castings. The principal feature, and the one that finally led to noiseless and successful working, is the use of independent exhaust valves. The induction valves are moved by the auxiliary cylinder shown on the top. The working of the machines is quite noiseless, and there is not the least jar even when 500ft. of heavy pump rod are connected with the engine.

Four of these large pumping engines are now working with driving "heads" as follow:—One with 336ft., two with 460ft., and one with 720ft. The efficiency of the engines has been carefully tested, and is found to be 75 per cent. The firm guarantee this efficiency for all engines when the diameter of the main cylinders is 12in. or more.

Digitized by Google

The illustrations show the details of one of these pumping engines constructed for the Plumas Eureka mine in California, to operate under a head of 720ft.—*i.e.*, with a pressure of 310lb. per inch. A is the main cylinder, B B induction pipes, the water entering at C. In the two boxes D D are two plain slide valves actuated by the auxiliary hydraulic cylinder E. This cylinder E is controlled by a small slide valve in the box F, which is operated by the sliding tappet G and the rod H. The stop collars I on H are moved by the bracket J, which is mounted on the cross-head at K. The tappet G, shown in the plan, is one of the "pass through" type, and acts some time in advance of the main valves. The exhaust pipes L L extend from the valve boxes D D down to two balanced cylindrical valves at M, which control the exhaust flow as it passes to the waste pipe P. This is the main point in Mr. Knight's invention, and the

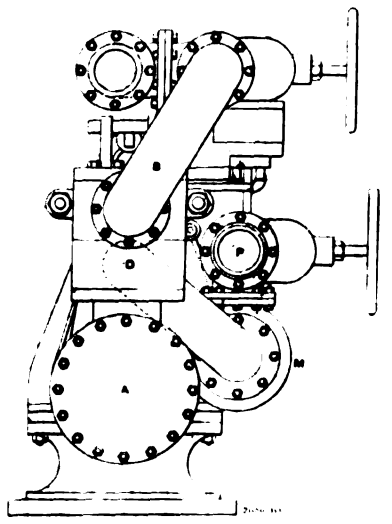

FIG. 4. BACK END VIEW.

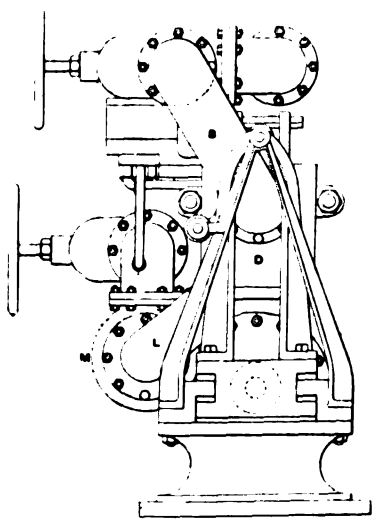

FIG. 5.—FRONT END VIEW.

secret of smooth working in his machines. These two piston valves at M are operated by a lever N, and a second tappet rod O, which imparts a slow movement to the valves. The valves thus begin to close and choke the exhaust soon after the piston has reached its maximum velocity, and gradually bring the water, and also the heavy pump rods, to a state of rest at the end of the stroke, just as a crank would do. As the tappets on the rod H outrun the main valves at D D by a foot or more of piston movement, it leaves the range of stroke to be controlled by the rod O and the retarding valves at M, so that by shifting the collars on the rod O the reciprocating parts can be cushioned and brought to a state of rest, avoiding all shock and danger to the pipes or machinery. We may explain that the pipes for conveying water in the mining districts of California are mostly of thin sheet iron, and so connected that the least shock is liable to rupture them. In this matter Mr. Knight has found his greatest difficulty, and, besides arranging his engines in the manner explained for easy cushioning, has to place air vessels on the pipe lines to avoid shock.

Notices of Meetings.

INSTITUTE OF MARINE ENGINEERS.—Tuesday, April 29th, at 7.30 p.m. Paper on "The Churchill Governor," by Mr. J. D. Churchill.

SOCIETY OF ARTS.—Wednesday, April 30th, at 8 p.m. "Photographic Lenses," by Mr T. R. Dallmeyer.

PHYSICAL SOCIETY.—May 2nd, at 5 p.m. (1) "The Distribution of Flow in a Strained Elastic Solid," by Mr. Charles A. Carus-Wilson; (2) "Photographs of Rapidly Moving Objects" and (3) "The Oscillating Electric Spark," by Mr. C. V. Boys.

THE INSTITUTION OF CIVIL ENGINEERS.—Students' Meeting, Friday, April 25th, at 7.30 p.m. Paper to be read: "Some Applications of Electricity in Engineering Workshops," by Mr. C. Frewen Jenkin, B.A. Ordinary Meeting, Tuesday, April 29th, at 8 p.m. Resumed discussion upon the papers by Sir Frederick Bramwell, on "Welding by Electricity," and by Mr. John Robinson, on "The Barry Dock Works"—the latter time permitting.

ROYAL INSTITUTION.—Annual Meeting, Thursday, May 1st, 1.30 p.m.

GEOLOGISTS' ASSOCIATION.—Friday, May 2nd. Papers to be read: "On the Manufacture of Serpentine in Nature's Laboratory," by Major-General C. A. McMahon, F.G.S.; "On a New Species of Capulus," by Professor G. S. Boulger, F.L.S., F.G.S.; "Note on the Occurrence of Amberite (Retinite), or Fossil Gum, in a Seam of Coal at Kawa-Kawa Colliery, Bay of Islands, New Zealand," by Mr. T. P. Moody.

INSTITUTION OF MECHANICAL ENGINEERS.—Thursday and Friday, the 1st and 2nd May. Paper to be read: "Further Report of the Research Committee on Marine Engine Trials," by Professor A. B. W. Kennedy.

PRICES CURRENT, 23RD APRIL, 1890.

Quotations at per ton, unless otherwise specified.

Tin: Straits	90	0	0	"	90	10	0
" Australian	.....			"	.....		
" English Ingots	95	0	0	"	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: The visible supply of raw copper increased about 700 tons during the first fortnight in April, owing to the Chili charters having exceeded, and deliveries being less than, those of the previous fortnight. On the other hand, there is a scarcity of spot metal offering, especially of the better sorts, so that the market has been moderately steady. Quotations for Chili bars to-day are £48 2s. 6d. to £48 10s. cash. Manufactured continues in slow demand, and prices remain at £61 sheets and £64 bottoms.

TIN: An active trade has taken place in tin during the week, and prices are firmer. On the 16th foreign was quoted £89 2s. 6d. to £89 10s. cash, but, owing to the better demand, values have advanced, quotations to-day being £90 to £90 10s.

LEAD: A stronger tone is also noticeable in lead, and prices are slightly higher.

SPELTER keeps very flat, owing to the condition of the galvanising trade, and prices are lower in England, although on the Continent they are well maintained, stocks being inconsiderable.

SHIPBUILDING NOTES.

ON the 19th inst. Messrs. Raylton, Dixon, & Co. launched from their yard, Middlesbrough, a steel screw steamer of the following dimensions:—Length over all, 287ft.; breadth, 39ft.; depth, moulded, 21ft. 3in.; and deadweight capacity, 3,300 tons. Her engines will be supplied by the North-Eastern Marine Engineering Company, Limited, Sunderland. On leaving the ways the boat was named "Dolores."

ON the 19th inst. a steel screw steamer, named the "Michigan," was launched from the shipbuilding yard of Messrs. Harland & Wolff, Belfast. Her principal dimensions are:—Length between the perpendiculars, 370ft.; breadth, 44ft.; depth, 30ft. 6in.; and tonnage, 3,700. The engines and boilers will also be supplied by Messrs. Harland & Wolff. The vessel will also be fitted throughout with electric light. The "Michigan" has been built to the order of the Atlantic Transport Line Company, and is intended for the American cattle trade.

HOME INDUSTRIES.

LONDON, 24th April, 1890.

The Money Market.—Money has become very easy, and loans are obtainable to any extent at 1 per cent., and even under. The discount market is kept firmer by the lowness of the Paris rate of exchange and the consequent demand for gold for export to France. The stock markets maintain a healthy degree of firmness without much real strength. There is not a great deal of investment buying, and speculative activity is confined to professional dealers. The more substantial railway stocks are left alone, but there has been a good deal of activity in those of the passenger lines, notably the underground railways. The American railway department, which for weeks has been a dead letter here, has become much livelier, and there has been a good deal of buying of the cheaper stocks which are progressive. Mexican Central Railway bonds are being bought for investment. Canadian Pacific shares are strongly in favour, and a marked advance in price has been registered in the past week. Grand Trunks attract little attention for the time. Foreign stocks show few movements of note, and the tone is steady. South American securities have been prominent. Argentine stocks recovered steadily as the gold premium fell, and Uruguay bonds have risen in sympathy. There has been a considerable drop in Peruvian bonds, as the prospects of the new Development Corporation have not been regarded as immediately bright. Mines have been a neglected market, The Rio Tinto dividend of 10 per cent. for last year was not very heartily received. South African gold shares—at least, the best of them—have recovered a trifle. Industrial and miscellaneous securities present no special feature.

Companies.—The following companies have been registered since our last report :—Buersil Cotton Spinning Co., Ld., with a capital of £20,000 ; Edgar Allen & Co., Ld., with a capital of £100,000, to purchase a steel manufacturing business ; Llanbedr Mining Co., Ld., with a capital of £5,000 ; The Fibre Syndicate, Ld., with a capital of £50,000, to work a patent for the treatment of vegetable fibre ; The Canal Mills Co. (Clayton-le-moors), Ld., with a capital of £50,000, to carry on the business of cotton spinners, &c. ; Parcocha Iron Ore and Railway Co., Ld., with a capital of £510,000, to carry on business as miners, &c. ; Dutton-Green Brick and Tile Works, Ld., with a capital of £20,000 ; Caedafydd Colliery Co , Ld., with a capital of £3,000 ; The Transvaal Leather Co., Ld., with a capital of £100,000 ; Cheltenham Omnibus Co., Ld., with a capital of £5,000 ; Samuel Yarwood & Son, Ld., with a capital of £37,000, to carry on the business of tanners, &c. ; Stanley Gold Mines, Ld., with a capital of £130,000 ; Friedenthal & Co., Ld., with a capital of £20,000, to carry on the business of engine and boiler makers, &c. ; The Paszowa (Galician) Petroleum Co., with a capital of £55,000 ; The Robottom Boracic Acid Syndicate, Ld., with a capital of £5,000 ; The Mexican English Syndicate, Ld., with a capital of £50,000, to investigate mines, &c. ; Peter Walker & Son (Warrington and Burton), Ld., with a capital of £2,000,000, to carry on the business of brewers.

The Central Underground Railway.—The Bill for the construction of the Central London Railway is now before the Select Committee of the House of Commons. The line is to run from Bayswater, along Oxford Street and Cheapside, at a depth of 60ft. The cars are to be worked by electricity.

Pullman Cars.—Hitherto the Midland and the London, Brighton, and South Coast Railways have been the only ones to adopt the Pullman car as used in America, and even they have found that our insular prejudices on the point of privacy have been inimical to a great extension of the Pullman system. The London and South-Western have recently imported two cars from America, and they are to be used experimentally on their London and Bournemouth trains. The new service commenced on Monday last, and the Duchess of Albany was one of the passengers on the maiden trip.

Gunboats for the Zambesi.—The British Government has recently entrusted Messrs. Yarrow & Co., of Poplar, with the construction of two steel shallow draught steamers to serve as gunboats for the navigation of the Zambesi and Shiré. These boats merit attention owing to the novelty of their construction. They are of the stern-wheel type, 90ft. in length by 16ft. beam, and having a draught of from 18in. to 2ft., and are of about the same tonnage as the passenger steamers plying between London Bridge and Chelsea. They will be shipped in pieces and put together at their destination. The most remarkable feature of Messrs. Yarrow's contract is that they have undertaken to put them together at the mouth of the river and have them ready for steaming within twenty-four hours after arrival without going ashore or having any recourse to the land on either side of the river. At the same works there are being built, side by side with the English boats, six boats for the Portuguese Government, also for service in the same district.

The Iron and Steel Institute.—The annual meeting of the Iron and Steel Institute will be held on Wednesday, Thursday, and Friday, the 7th, 8th, and 9th prox., at 10.30 a.m. each day. After the Bessemer Gold Medal for 1890 has been presented to Mr. William D. Allen, of Sheffield, the following papers will be read and discussed : "A New Form of Siemens Furnace," by Mr. John Head ; "The Robert-Bessemer Process," by Mr. Lynwood Garrison ; "Some Critical Points in Iron and Steel Manufacture," by M. F. Osmond ; "The Carburisation of Iron by the Diamond," by Professor W. C. Roberts-Austen ; "The Action of Aluminium on Iron and Steel," by Sir Henry Roscoe ; "The Changes in Iron Produced by Thermal Treatment," by Dr. E. J. Ball ; "Certain Chemical Phenomena in the Manufacture of Steel," by Mr. W. Galbraith ; and "The Rollet Process for Producing Purified Pig Castings," by M. Rollet.

A New Chair of Electrical Engineering at King's College, London.—We understand that great efforts are being made by the Council of King's College to meet the growing need of additional teaching power in the department of electrical engineering. The engineering department of this college has always had a high reputation, and now, thanks to the munificenee of Lady Siemens, a new laboratory for electrical engineering, to perpetuate the name of her distinguished husband, and to be called the "William Siemens Laboratory," is to be constructed and fitted with every modern electrical appliance. Through the kindness of the well-known engineers, Messrs. Davey, Paxman, & Co., of Colchester, the Council are enabled to equip a fine engine and boiler room with all the machinery requisite to provide the necessary power, and it is hoped that by this means the whole College will ultimately be lighted by electricity. A new chair of electrical engineering has been established, and the first Professor has been appointed—namely, Dr. John Hopkinson, F.R.S., the President of the Institution of Electrical Engineers. We cannot but express our pleasure at this appointment, as no better selection could be made to undertake the direction of the new laboratory. It is hoped that the new arrangements we have mentioned will commence with the October session.

Electric Welding.—On Friday evening, the 18th inst., Sir Frederick Bramwell gave an interesting lecture on "Welding by Electricity," at the Royal Institution, Albemarle Street. The lecture may be considered as supplemental to one given by the lecturer on the previous Tuesday at the Institution of Civil Engineers. In the early part of his discourse Sir Frederick Bramwell gave a general description of the smith's art, especially in relation to welding, and expressed a high opinion of the smith's skill, with which we entirely agree. After this some experiments were shown of electric welding, in which hard cast steel, copper, aluminium, and iron tubing were welded, and afterwards bent over the anvil to show the quality of the welding.

The African Kola Nut.—A paper, by Mr. T. Christy, was read the other night at the meeting of the Balloon Society, St. James's Hall, on the African Kola Nut, concerning which many remarkable statements have recently been published. The kola nut is held in great respect by the natives of the Western Coast of Africa, on account of its wonderful stimulating and sustaining powers. The nut is ground into a fine powder and carried about the person during long journeys, when often the only sustenance consists of a "chew" of this kola ; thanks to it many have been able to stave off thirst and hunger, while others declare that after a severe day's work or marching nothing so revives the system as a kola nut. As a basis for a beverage, the analysis published comparing the nitrogenous principles, chemically defined and crystallisable, kola takes precedence over tea, coffee, and cocoa, while, owing to the almost entire absence of tannin in it, it does not injure or impair the digestive organs.

MANCHESTER, 24th April, 1890.

The Ship Canal.—A Bill is being promoted by the Ship Canal Company to authorise them to substitute fewer tidal openings into the Mersey than were fixed by the Act of 1885. The total width of the openings is to be reduced from 4,500ft. to 1,800ft. The Mersey Dock and Harbour Board oppose the Bill, on the ground of injury to the estuary owing to diminished flow, and the same ground is taken by the Widnes Corporation and the London and North-Western Railway Company.

Proposed High-level Bridge.—A company is being formed, with a capital of £100,000, to construct a bridge from the town of Douglas, in the Isle of Man, to Douglas Head, at the other side of the harbour. A large amount of capital has been already obtained in Manchester and district. A tower is to be erected on the Douglas side, 380ft. high, with five platforms, which are to be utilised for various purposes. From one of the platforms a lattice bridge will be carried over to the Head. Lifts are to be fitted similar to those in use on the Eiffel Tower. The engineer to the scheme is Mr. Thomas Floyd, C.E., 2, Victoria Mansions, London.

The Cotton Trade.—The condition of the cotton trade, so far as yarn is concerned, is not unsatisfactory, although the advance in cotton has rendered business somewhat difficult. The price of middling American is now $6\frac{5}{16}$d. per lb. in Liverpool. The consequent increase in the price of yarn checks the trade in cloth. An attempt is being made in Liverpool to create a market for futures in Egyptian cotton. The Bolton spinners entertain a strong opinion as to the unwisdom of any step of this kind, and they will probably resort to extreme measures to prevent it. This trade is in a comparatively limited number of hands, and spinners of Bolton counts are therefore able more easily to continue to promote their common interests than spinners of ordinary counts. Generally the tone of the market in yarns is firm, with no undue tendency to sell.

The Engineering Trade.—Employment in the general engineering trades does not yet show much sign of falling off, although there are complaints here and there. Tool makers are generally finding plenty of work, and for home and foreign railways especially there are a number of orders coming forward. Messrs. Craven Bros., Limited, are making an addition to their premises, and Messrs. Hulse & Co. have nearly finished their new shops. Machinists are mostly still well employed, although there is not quite the pressure in some departments that there was. Mules and ring frames are, however, well ordered, and in most cases sufficient work is in hand to last the year.

The Linen and Jute Trades.—Business during the week has been of an unsatisfactory character in the heavy departments. A little activity has been noticeable in fancy descriptions, but the total turnover has not been large. The complaint is general that orders in most branches of the trade have been scarce owing to the unsatisfactory weather that has prevailed for some time. Buyers are hanging back in consequence of this, and the leading home trade houses are feeling the effects of this condition of affairs. With regard to the shipping inquiry, trade is not brisk in the South American quarter. The high premium on gold, which was advanced still further the other day, is a serious drawback, not only delaying remittances, but causing orders to be withheld. United States buyers, however, have come forward more freely in view of contemplated tariff legislation, and have operated to a fair extent in both fine, medium, and coarse makes. Linen threads are inquired for to a considerable extent, especially in the ready-made clothing districts, which, notwithstanding the use of cotton thread for the common varieties of clothing, still absorb large quantities of the linen article.

GLASGOW, 24th April, 1890.

Pig Iron.—The heavy fall in pig iron prices during the past few days has brought several outside speculators into trouble. In January the price of warrants was up to 66s. 3d., on Tuesday last it reached 44s. 10d. This fall of 21s. 5d. in three months is quite phenomenal, and has, as might be expected, produced some failures, one to the extent of £100,000. This serious fall is all the more remarkable that shipments are going up and stocks are going steadily down. The explanation of it is that outside speculation rushed the price up above its normal amount and the reaction has come. So long as there is a feeling of uncertainty about the future of general trade, and so long as the stocks are so heavy, any permanent and considerable advance in the price is hardly to be looked for.

Shipping.—The Gem Line Steamship Company, Dundee, at a meeting on Thursday, declared an interim dividend of 5 per cent., making 10 per cent. for the year. The company are building a large steamer from the reserve fund.

Shipbuilding.—Messrs. Ramage & Ferguson, Leith, have secured an order to build a 350-ton steel steam yacht for Mr. Harry Taylor, late owner of the well-known schooners "Bluebell" and "Hildegarde." The vessel will be fitted with triple-expansion engines, having cylinders 15½in., 25in., and 40in. diameter, by 27in. stroke. Besides this steam yacht, Messrs. Ramage are laying down one of 600 tons.

Contracts Open.—The new railway which the Caledonian Railway are constructing from the extreme east end of Glasgow, underground to the west end, will require a large quantity—about 10,000 tons—of girders, &c.

Scottish Railways.—The centre of interest at the moment is the Select Committee of the House of Commons which has been appointed to consider a group of Scottish Private Bills. The first to come before the Committee was the North British and Glasgow and South Western Railway Bill, and it has been agreed to take the Caledonian Bill next. The preliminary statements were made this week. Mr. Pope, Q.C., appears for the North British Railway Company, and Mr. Bolton for the Caledonian. The subject is exciting great interest in Scotland, especially in the districts where the Glasgow and South Western and the Caledonian Railways now compete against each other. The west coast is the district mainly affected. Should the North British succeed with their scheme they would have lines on both sides of the Clyde, whereas, should the Caledonian succeed, they would have two lines on one side. Should the Glasgow and South Western Railway go over to the Caledonian, the Midland would be practically shut off from the west coast traffic, whereas acquisition by the North British Railway would maintain the *status quo* in this respect.

(From our own Correspondents.)

LIVERPOOL, 23rd April, 1890.

The Canadian Emigration Season.—The emigration season has now fully set in, and the various railway stations are occasionally crowded with emigrants from different European countries on the way to their new homes out West. The "Sardinian" and the "Lake Ontario" sailed last week with nearly 2,000 emigrants on board. There are several societies in England directed by philanthropic people, and formed to assist agricultural men and women to emigrate. They are sent out in batches under the care of an agent, who looks after their interests until they arrive at their destination. Seventy emigrants on board the "Sardinian" were going to Lord Brassey's farm of 30,000

Digitized by Google

acres near Indian Head; each family will have secured to them 160 acres, and capital upon easy terms will be advanced to them.

THE DOCK LABOUR AGITATION.—A very determined attempt was made last Friday and Saturday by some agitators to induce the labourers to renew the dispute with the shipowners upon the paltry excuse of the half-day ceasing at 11 o'clock instead of 12. The movement was a failure, and with very few exceptions the men continued at their work. The agitators are very much chagrined that the last strike was settled over their heads; and, without any recognition, "their occupation's gone."

LEEDS, 23RD APRIL, 1890.

THE IRON AND STEEL TRADES.—The state of the manufactured iron and steel trades of Leeds and surrounding district is a reflex of the quiet tone which marks the English and Scotch iron markets. Business has decidedly fallen off during the last month or two, and though the outlook does not appear very bright, some are not without hope for a return to a better state of things ere long. The declared intention of blast furnacemen to restrict the output of pig iron finds support among the Cumberland men. A limitation of production would, it is said, have the effect of temporarily increasing prices and steadying the market, which has, more or less, been very fluctuating during the greater part of the present year. Although orders are not coming in quickly, and notwithstanding that there is a less demand for best Yorkshire iron boiler plate, Leeds iron manufacturers, unlike some of the makers in the Midlands, are able to keep their works going full time. Old orders are also keeping the engineering branches actively employed. In the local engineering trade the past week has been remarkable for a general meeting of the operatives. They gathered together on Saturday, and unanimously decided that the present time is opportune for making a demand for an increase of 2s. all round in the following trades:—Pattern makers, smiths, turners, fitters, millwrights, borers and planers. It was stated at the meeting that Leeds was the lowest paid centre of engineering, and that the General Executive (London) were determined that wages in the town should go up. The strike in the Halifax iron trade is not yet settled. Some firms have conceded the men's demand for an advance of 2s. a week, and the points as to overtime.

THE COAL TRADE. The collieries in West Yorkshire continue to be active, though prices have nearly dropped to what they were before the miners recently struck. Manufacturing fuel is easier to buy, on account of a lessened inquiry for coke. The consumption of coke, however, is larger than it was, some of the furnaces in North Lincolnshire having again been blown in.

SHEFFIELD, 23RD APRIL, 1890.

IRON AND STEEL.—A very quiet tone prevails throughout the whole district in the iron trades, and, although there is no scarcity of employment as yet, there is a downward tendency in prices all round. All the large firms continue to be well employed, particularly on railway materials of all kinds. Marine work is coming in rather slowly just now.

COAL AND COKE.—Coal is decidedly falling off in value. Coke is also slightly lower in value, due, no doubt, to the lessened demand of smelters in the North of England. Smiths' coke maintains its value all round.

NORTH STAFFORDSHIRE, 23RD APRIL, 1890.

THE IRON TRADE.—There is no improvement to be reported with regard to the iron trade. Many mills are standing for want of orders, and a feeling that the worst has not been reached appears to prevail. Buyers have no confidence in the market, and believe by withholding orders they will be able to place them at still lower prices. Pig iron has dropped to 52s. 6d. per ton, and it is difficult to see how it can be manufactured at that figure. Unless a change occurs, there will have to be some attempt made to reduce the cost of production.

THE COAL TRADE.—The demand for forge and manufacturing fuel has fallen off considerably since the commencement of the year, and prices are showing signs of weakness. As prices in this district have only been advanced in proportion to the rise in colliers' wages, any serious fall without a corresponding decrease in the cost of production will mean a heavy loss to colliery proprietors.

THE NORTH STAFFORDSHIRE CHAMBER OF COMMERCE.—The annual meeting of this chamber was held last week, when Mr. W. M. Edge was elected president for the ensuing year. The opening of the new technical museum by Princess Louise has had to be postponed owing to the preparations of the committee being still far from complete.

THE MASON SCIENCE COLLEGE, BIRMINGHAM.—At the last meeting of the Mason College Engineering Society, Professor R. H. Smith in the chair, Mr. J. Knight read a paper, "On the Use of Cast and Wrought Iron for Pipes, and the Relative Advantages of the Two Materials." Mr. R. Pierce followed by reading a paper "On the Use of Steel for Making Pipe Mains," and described the various processes of making riveted and welded pipes from steel plates. Mr. T. Arnall then read a paper, "On the Joints used for Various Kinds of Pipes, and the testing of pipes at the works of the manufacturer, and after they are laid in the trenches." The three papers were taken as one, and the reading of them was followed by a lengthy discussion.

CARDIFF, 23RD APRIL, 1890.

IRON AND STEEL.—The pig iron trade continues most unsatisfactory, and unless the prices rise makers will be compelled to reduce the output, as the difference between normal prices for raw material and fuel, as compared with pigs, is getting greater every week. There is a strong feeling that, the speculative element having had its day, a gradual and steady business will ensue. The ironmasters have decided to reduce the price of steel tinplate bars from £7 15s. to £5 10s.—a remarkably significant step. In iron ore a fair amount of business has been done during the week. Rubio ore is quoted at 15s. 9d. c.i.f. Cardiff and Newport, 16s. Swansea, 17s. Glasgow. Freights from the ore ports are a little easier.

COAL AND COKE.—There is very little inquiry for steam coal this week, but the large amount of coal sold forward under contract enables colliery owners to maintain their prices at last week's figures. In fact, those sellers who are independent of bye-orders are firm in their quotations. There is a feeling of depression gradually creeping over all departments of industry; shipowners seem to be affected most, as freights in all directions, with the exception of America, have been unremunerative. The demand for house coal is getting less as summer approaches, and a reduction of 1s. per ton has to be conceded in order to effect business. For coke prospects are fairly healthy, although the high prices of January have disappeared.

BARROW-IN-FURNESS, 23RD APRIL, 1890.

HEMATITE PIG IRON.—A further depression is noticeable in hematite pig iron. Buyers who have orders to place are only purchasing just sufficient metal to meet current wants, as they anticipate much lower prices; but it is probable that values will not go down to a much lower point because makers have agreed on a reduction in the output. During the week one of the furnaces at the Moss Bay Iron and Steel Works has been blown out. It is reported that the other furnace at Moss Bay will be blown out, and that the adjoining steel works will be kept going with supplies of hematite warrants. Several makers on the West Coast intend limiting the production of iron until prices have assumed such a position as to give a profit to the smelter. Hematite warrants have been freely bought at 53s. 6d. during the week.

STEEL. There is a still quieter tone in the steel trade, and orders are few in number. The business doing in rails is very limited, and makers have reduced their prices for heavy sections to £5 per ton. Steel shipbuilding material is in quieter demand, and makers are quoting £7 5s. for plates and £6 15s. for angles. It is thought highly probable that the cheapening tendency of steel shipbuilding material will lead to the placing of orders for large steamers.

IRON ORE.—There is less inquiry for iron ore, and prices are lower at 11s. 6d. to 16s. per ton net at mines for ordinary qualities.

MIDDLESBROUGH, 23RD APRIL, 1890.

PIG IRON.—The pig iron market is quite demoralised. Prices are falling, though the conditions are such that one would expect them to be rising. The calculations of the shrewdest have been baffled, and there is something like consternation all round. There is not much business done, as buyers are holding off for lower prices still. Meantime the makers are in a sad plight between high prices for raw materials and wages and low prices for the manufactured article. The makers' price for No. 3 G.M.B. Cleveland is about 50s. per ton, but warrants are only 45s. 6d. on the average, and therefore are preferred. Makers have had to break their price, and have made more sales than they have done for some time. East Coast hematites are quoted nominally at 70s., but nothing like this can be had so long as West Coast hematite is so low. The stock in Connal's stores on Monday amounted to 135,988 tons, against 139,359 tons a week ago, being a decrease of 3,371 tons.

SHIPMENTS OF PIG IRON.—The shipments are improving as the season advances, but they are still far behind those of last year. Up to Monday last they amounted to 54,905 tons, against 38,936 tons to the 21st of March, and 74,519 tons to the 21st of April last year.

MANUFACTURED IRON AND STEEL.—Iron and steel are duller than ever. There are few inquiries and fewer orders, and prices have fallen in consequence. Iron ship plates are at £6 5s.; angles, £6 2s. 6d.; bars, £6 7s. 6d.; steel ship plates, £7 7s. 6d.; angles, £7 7s. 6d.; steel rails (heavy section), £5 7s. 6s. per ton f.o.t. at manufacturers' works, less 2½ per cent.

SUNDERLAND, 23RD APRIL, 1890.

SHIPBUILDING.—The dearth of orders, and even of inquiries, continues, and there is now little prospect of an early improvement; in fact, a general feeling prevails that prices will before long be much lower. It is reported that existing contracts are being cancelled, and that shipowners are paying shipbuilders large sums as compensation for cancellation.

SHIPPING.—There is no marked improvement to note in the freight market, and opinions are divided as to whether this year rates will be lower or about the same as last year. In any case the prospect for shipping investors is not bright, as the working expenses have increased, and there is no probability of a curtailment in the cost of bunker coals. The local shipments of coal are about the same as usual. For home ports 33,620 tons were shipped, an increase of 3,802 tons, and to foreign 37,648 tons, an increase of 21,178 tons. The shipments coastwise also included 16,000 dozen glass bottles, 2,600 quarters of wheat, 250 tons of patent fuel, 180 tons of lime, 20 tons of cement and other British goods, and foreign shipments also included 300 tons of coke and 500 tons of pitch. The imports for the week comprised 19 cargoes of timber, silver sand, block ice, and 25,520 sacks of wheat.

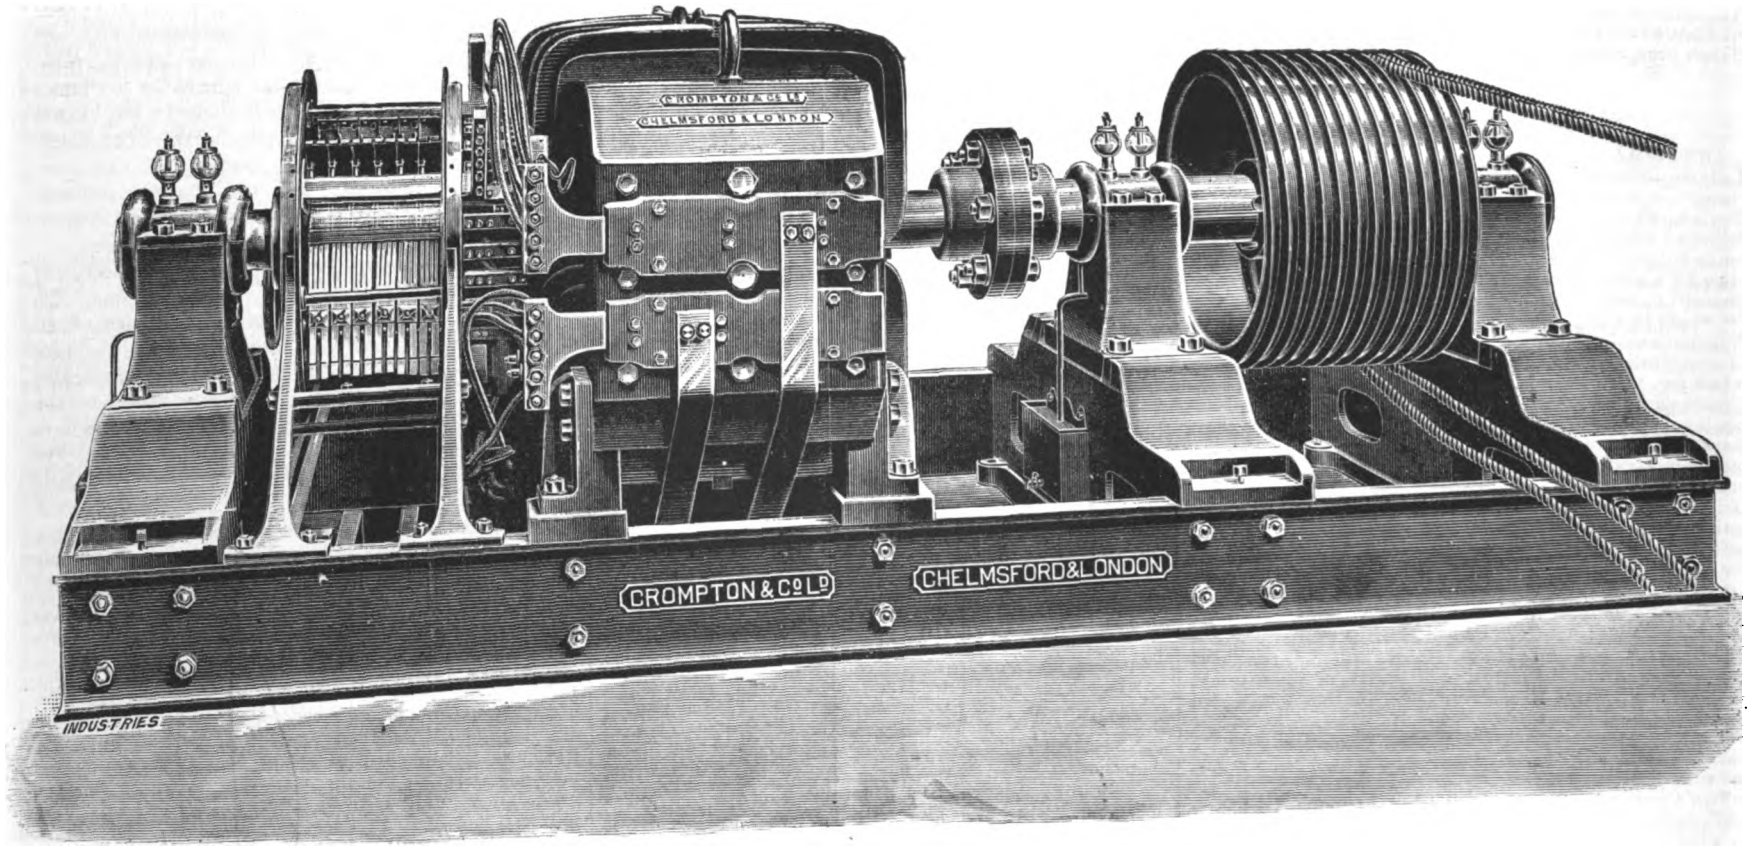
NEWCASTLE, 23RD APRIL, 1890.

THE IRON TRADE.—In the pig iron trade business continues flat, and holders find it extremely difficult to get rid of their stocks, even at the reduced rates now ruling. The demand for finished iron has also largely fallen off, and prices have declined nearly 40s. per ton from the highest point attained. Many of the manufacturers have orders sufficient to keep their works fully going up to the end of the year, but specifications are now coming in very slowly, and some difficulty is, consequently, experienced in keeping the machinery continuously in operation. The outlook, on the whole, is depressing, and manufacturers themselves are the least sanguine as regards any prospective change for the better.

THE COAL TRADE.—A lessened demand for almost all qualities of coal is being felt, and it is scarcely probable that prices can long be maintained at their present level. There was a more than usually heavy shipment of coal and coke at Tyne Dock in the week ending April 19th, this being doubtless due to the deficient shipment effected in the previous week. The figures were 121,125 tons, as against 80,626 tons shipped in the six days ending April 12th.

GALVANISING WORKS.—The Tyne Galvanising Works are just now doing a very satisfactory business, the quantity of material dealt with being not less than 60 tons per month. The falling off of business in the iron trade, however, will naturally have an adverse effect on this minor industry, and coming dulness may therefore be looked for.

NEW ENGINEERING WORKS. Messrs. Haggie Brothers, wire rope manufacturers, colliery engineers, &c., Gateshead, are now erecting a large building, which is to be principally used for the extension of their engineering business. The building covers the extensive area formerly occupied by the firm's hemp rope factory, and is in the immediate vicinity of their present engineering and wire rope manufacturing works. It will be fitted with the best modern machinery, and will more than double the firm's present productive capacity in engineering specialties. The firm intend to develop the business of gas engineering, in which they have hitherto been engaged to a limited extent, and also contemplate utilising a portion of their new premises for the extensive carrying on of plumbing work and its auxiliary branches. The wire rope works, too, are to be extended, the business of the firm in this line being now very active, in spite of the keen competition existing. The firm's programme is a very comprehensive one, and when fully carried out cannot fail to be productive of great good to the locality in which the works were situated.



DUNDEE, 23RD APRIL, 1890.

JUTE AND FLAX TRADES.—There is a movement in the local trade here in favour of the conversion of some of the largest firms into limited liability companies. Two works in the district have already been some years in the hands of companies, and it is announced to-day that the business of Messrs. Gilroy, Sons, & Co., Tay Works, Dundee, has been sold to a London syndicate for £400,000. The firm takes £175,000 in part payment of its mills and calenders, which are very extensive. It is believed that the London syndicate which has purchased Messrs. Gilroy's business is negotiating for the purchase of several other large works in the town. The jute trade is at present showing signs of revival again. Prices have gone up in New York, burlaps 40 in 10½oz. being now quoted at from 5½c. to 5¾c. per yard. It is believed here that merchants on the other side are buying up in the expectation that jute bags will be extensively used in the construction of the Mississippi levees. Jute bags filled with concrete or other material have been used in this country in the construction of piers and breakwaters. The authorised copy of the New United States Tariff, which has now been published, tends to confirm the fear that the new duties will have an unfavourable effect on the Dundee trade should they obtain the approval of Congress. The arrangement made with Greece, whereby the import duties on jute and linen goods are to be reduced in return for the reduction of the duty on currants, will help to increase our trade in the East, which is already considerable. Manufacturers of jute goods are now well booked forward, and prices all over are firmer. Jute yarns are in strong demand, and prices are advancing. There is a fair business passing in linens on home account, and stocks are moving off. Flax and tow yarns meet with a good sale, but prices do not show signs of improvement.

FOUR-POLE DRUM DYNAMO.

CONSTRUCTED BY MESSRS. CROMPTON & CO., ELECTRICAL ENGINEERS, ARC WORKS, CHELMSFORD.

FOUR-POLE DRUM DYNAMO.

THE above illustration shows a new four-pole drum machine made by Messrs. Crompton & Co., Ld., electrical engineers, Chelmsford. We feel confident that the single magnet two-pole drum dynamo now in almost universal use will give way to the four-pole type for sizes above 200 watts per revolution. The four-pole machine seems to have everything in its favour. The end couplings, which are the most troublesome part of two-pole machines, are beautifully simple when four poles are used, as the connections are only a quarter round the armature, and do not tend to foul the spindle or to block up ventilation spaces. Besides this, they are infinitely more accessible, a point of great importance with reference to repairs. If a four-pole machine has the same number of active conductors, the loss by hysteresis in the armature is approximately the same as in a two-pole machine, for, though the iron is reversed twice as often, there is only about half the volume; or if, on the other hand, the radial depth is kept as before, the induction is very much lower. For large currents the four-pole drum is especially suitable, as the current in each conductor is one-fourth of the whole current, and the commutator sections are more numerous than in the corresponding two-pole machine.

The machine we illustrate has an output of 50 volts and 2,500 amperes at 400 revolutions per minute. The armature has 48 external conductors of 185 strands of No. 16 B.W.G. twisted and compressed into a rectangular cross section. The armature diameter is 22in. It is built of discs keyed to a soft steel spindle. The spindle is made in two parts, coupled by a cast iron coupling, and fitted with a pulley for rope driving. There are three bearings, and these have only the bottom brasses lined with white metal. The magnets are wound with thirteen layers of copper strip 0·19in. by 0·24in., resistance cold 0·9 ohm, all in series. The magnets are 26in. by 11½in. There are four sets of six brushes each. The opposite brushes are coupled together in parallel. Each brush is 2in. wide. The machine is mounted on a bedplate built up of two channel girders of wrought iron, to which the pedestals of the magnets and the bearings are bolted.

One of the chief advances in this machine is the engineering design of the armature conductors. These have faced joints, and are screwed together with steel bolts and nuts. So perfect is this system, and so simple are the end connections, that the whole armature can be stripped in four hours, and put together in a somewhat longer time, including new bands. A repair, if ever necessary, could be executed in a very short time, unless, of course, the bands had to be taken off. This dynamo is for smelting work, a branch of electric business in which, as is well known, Messrs. Crompton have been particularly successful.

CLYDE SHIPBUILDING FOR MARCH.

THE general downward tendency of freights, together with the high prices paid for labour and material, is doubtless the cause of the almost total cessation on the part of shipowners of entering upon negotiations for new ships. Nothing of importance in the way of new work has fallen to the shipbuilders in the Clyde district, and as there are very few inquiries in the market, the outlook for this important industry is far from encouraging. The total tonnage booked aggregates about 800 tons, and is made up of five small launches, and a twin-screw steamer of 700 tons, to be built for service on the River Plate, by Messrs. Russell & Co., Port Glasgow.

The output of tonnage was fairly up to the average, and comprised 13 steamers and 4 sailing vessels, aggregating 23,785 tons. Most of the vessels put into the water were of small size, the largest—the Gulf liner, "Gulf of Lyons"—only measuring 3,000 tons, and, without a single exception, were built of steel.

The following are the particulars of the vessels launched:—

SCREW STEAMERS.

Built by the Ailsa Shipbuilding Co., Troon:—s.s. "Vasna," 850 tons, 950 i.h.p. Engined by Messrs. Dunsmuir & Jackson, Govan, for the Indian coasting trade of the British India Steam Navigation Co.

Built by Messrs Caird & Co., Greenock:—s.s. "Gulf of Lyons," 3,000 tons, 2,000 i.h.p. Engined by the builders, for the general trade of the Greenock Steamship Co.

Built by Messrs. Fleming & Ferguson, Paisley:—A steel bucket ladder dredger, 500 tons, 450 i.h.p. Engined by the builders. Shipped in pieces to destination.

Built by Messrs. William Hamilton & Co., Port Glasgow:—s.s. "Vauban," 1,800 tons. Engined by Messrs. Blackwood & Gordon, Port Glasgow, to the order of Messrs. Maurel & Prom, Bordeaux, for general trade between France and the Senegal.

Built by the London and Glasgow Shipbuilding Co.:—s.s. "Lien Shing," 1,850 tons, 1,200 i.h.p. Engined by the builders, for the China trade of the Indo-China Steam Navigation Co.

Built by Messrs. Mackie & Thomson, Govan:—s.s. "Corsican," 340 tons, 500 i.h.p. Engined by Messrs. Muir & Houston, Glasgow, for the Channel and Continental trade of Messrs. J. Macfarlane & Co., Glasgow.

Built by Messrs. M'Knight & Co., Ayr:—s.s. "Ethelred," 900 tons. Engined by Messrs. D. Rowan & Sons, Glasgow, for the American fruit trade of the Macgregor Steamship Co., Limited.

Built by Messrs. Murdoch & Murray, Port Glasgow: s.s. "Rio Paraguay," 430 tons, 340 i.h.p. Engined by Messrs. Rankin & Blackmore, Greenock, to the order of Messrs. Morton & Williamson, Glasgow, for South American owners.

Built by Messrs. Napier, Shanks, & Bell, Yoker:—s.s. "Claudine," 850 tons. Engined by Messrs. Dunsmuir & Jackson, Govan, to the order of Mr. C. Spreckels, of San Francisco, for trade at the Hawaiian Islands.

Built by Messrs. J. B. Seath & Co., Rutherglen:—s.s. "Hippolyte Dumois," 600 tons. Engined by Messrs. Hutson & Corbett, Glasgow, to the order of Messrs. Curwen Bros., Liverpool, for the fruit-carrying trade between the West Indies and the United States.

Built by Messrs. A. Stephen & Son, Linthouse:—s.s. "Highland Chief," 2,700 tons. 240 n.h.p. Engined by the builders to the order of Messrs. J. Nelson & Son, Liverpool, for their meat-carrying trade.

Built by Messrs. J. & G. Thomson, Clydebank:—s.s. "Brazil," 2,000 tons, 2,400 i.h.p. Engined by the builders, for the Brazilian Steam Navigation Company, for their coasting trade.

PADDLE STEAMER.

Built by Mr. D. M. Cumming, Parkhead:—A steel paddle steamer of 85 tons, 250 i.h.p. Shipped in pieces to destination.

SAILING VESSELS.

Built by Messrs. Chas. Connell & Co., Scotstown:—"Melete," ship, 1,780 tons, for Hamburg owners.

Built by Messrs. Russell & Co., Port Glasgow:—Four-masted barque, "Elmbank," 2,200 tons, for Messrs. A. Weir & Co., Glasgow; four-masted barque, "Simla," 2,200 tons, for Mr. G. M. Steeves, Liverpool; and barque, "Edenballymore," 1,700 tons, for Messrs. Thomson & Dickie, Glasgow.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Two-page Supplement giving a General View of the Buildings and Grounds of the EDINBURGH EXHIBITION.

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," at our London Offices, 358, Strand, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

BOUND VOLUMES OF **Industries,**

In half calf, gilt lettered, may be obtained at our London, Manchester, and Glasgow Offices, Price 20s. each.

Industries:

FRIDAY, 25TH APRIL, 1890.

THE BUDGET.

A SURPLUS of over three millions and a half is a substantial indication that the trade of the past year has been expansive, and that, even if we have begun to go down hill a little, the going down is extremely recent. Mr. Goschen has been among the luckiest of Chancellors of the Exchequer. His difficulties have always been connected with the disposal of a surplus; he has never, like Sir Stafford Northcote, had to manœuvre a series of deficits. Yet, notwithstanding the luck of always having had several millions to dispose of, each one of Mr. Goschen's Budgets has been more or less disappointing. With the solitary exception of the Conversion scheme, his plans have shown that he has not availed himself to the full of his stream of good fortune. He has made a bite into several cherries, but he seems to have an unaccountable reluctance to attempt anything heroic. The most important proposals are the diminution of the tea duty and the reduction of the house tax for houses of a rental below £60. Some of his smaller benefactions are noteworthy. The sop to the Volunteers, following upon the defeat of the Government on the subject, will help the Volunteer regiments to get out of debt; and the minor rearrangements, such as the provision for the recoinage of light gold out of the profit on the silver circulation, the abolition of the duty on plate, and the reduction of the stamp duty on apprentices' indentures, are certainly steps, if small ones, in the right direction. In the latter item the reduction might very well have been carried a little further at an insignificant cost to the revenue. A stamp duty of 2s. 6d., even on an indenture, is too much; all that is necessary is to secure the legality of the instrument, and a merely nominal duty, say 6d., would quite suffice. It is almost certain that this would bring in much more to the revenue than a higher sum, since the drawing of an indenture is frequently—we might almost say, in certain industries, universally—avoided because of the expense of it.

That nearly two millions of the realised surplus in the past year's accounts were due to the increased yield of the duties on spirits is sufficiently remarkable. The main item of increase is in home spirits, where more than a million was realised beyond the estimate. From the point of view of the social reformer, it is no particular subject for congratulation that increased prosperity should be so closely attended by a larger liquor bill. From the point of view of the student of taxation, too, it is a serious problem how far we are going on the right lines in loading a single article with the bulk of our taxes—moreover, an article which is subject to fluctuations so considerable as alcohol. Connected with this subject is the manœuvre by which Mr. Goschen initiates a system of compensation for the withdrawal of public-house licences, and meantime a suspension of the system of granting new ones. The cost of this operation is estimated by Mr. Goschen at £1,250,000. This sum Mr. Goschen, with characteristic ingenuity of statement, proposes to make the spirit tax meet. He therefore increases the duties on foreign and home spirits by a surtax of 6d. per gallon, which he passes to the Local Budget, in addition to 3d. per barrel upon beer, extracted from the Imperial Budget for this purpose. This manœuvre, however, hardly conceals the faultiness of the finance, as the question of compensation is by no means a foregone conclusion.

The leading feature of the Budget is, however, the reduction of the tea duty by 2d. per lb. Mr. Goschen's wail to the middleman to be less hard upon the consumer was amusing; but his proposed reduction does not exhibit any particular regard for the consumer, or at any rate for the small consumer. Sir Stafford Northcote made a similar blunder in reducing the tobacco tax, for in that case the advantage went almost wholly into the pockets of the trader. In this case there is little doubt that the same thing will happen. Purchasers of half a pound of tea and upwards may benefit, but the smaller purchasers certainly will not, and thus the income tax of the poor, as it has been called, will practically remain as it is. It is fair to say that an analogous result would be produced by reduction of the income tax on large incomes and leaving the small ones alone. No doubt many high claims oppress the mind of a Chancellor of the Exchequer, but as a matter of fact there were no very urgent demands for reduction of the tea duties. If, however, tea was meddled with at all by way of reduction, a substantial reduction, which would have been felt by the small purchaser, would certainly have been more desirable than a nibble which does good to nobody but the wholesale merchant and the comparatively large consumer.

The important omission in Mr. Goschen's Budget, which may perhaps cost him much of the popularity he has gained as a public financier, is any treatment of the income tax. There is a certain amount of acuteness in the omission, for Mr. Goschen must have realised that the class chiefly benefited by the Budget would be the *élite* of the working class. The increase of the spirit duties will not touch them, or will only touch them slightly; the decrease of the house duties, and of the tea and currant duties, will favour them, while a contrary effect will be produced upon the class below this one, for the increase of the spirit duties will touch them seriously, and the relief of taxation will not touch them at all. It cannot be said that the Budget is based in the least upon scientific principles of taxation; it is purely empirical. There is no attempt to adjust the incidence, or to take off burdens all round, by dealing with direct taxation. The suggestion which Mr. Goschen made about permitting incomes under £400 a year to escape the tax, though attractive enough at first sight, is not a sound one, taken by itself. Let us have a graded income tax by all means; but let us not be so absurd as to leave taxation practically to settle its own incidence by evading the responsibility of directly taxing particular classes because they happen to be numerous enough to make an outcry. Mr. Goschen's assumption that an income tax at sixpence was as low as need be, is too calm. Taxes on shops and dwelling houses are practically income taxes on a large number of income tax payers, and some relief is afforded to the lower grades of these by the Budget; but the income tax itself is untouched. It is quite true that the reduction of a penny, now that it yields £2,200,000, is a much more serious sacrifice of revenue than it was when a penny yielded only £800,000. If Mr. Goschen had dealt drastically with the tea duty, probably no one would have seriously objected; but if he had made a rearrangement of the income tax relieving incomes up to £2,000, say by twopence per pound, and graduating the incomes above this, he would

Digitized by Google

have given an elasticity to trade which would have affected the whole industry of the country. The mere shuffling about of indirect taxation is after all a feeble method of finance, and, it goes without saying, gives nobody any satisfaction.

APPOINTMENT OF ASSISTANT ENGINEERS IN THE NAVY.

In a recent issue (see *Industries* of the 28th ult.), when writing of the position of engineers in the Navy, we mentioned that a step was about to be taken by which the teaching and practical advantages of different localities would be utilised in the training of young men who intended to enter the Navy as engineers, instead of taking them all from the same kind of establishment and forcing them all through the same narrow groove of instruction. We have now received copies of the regulations which have been made out by the Admiralty for the guidance of candidates for direct appointment as probationary assistant engineers in the Royal Navy, and, as they will interest a good many of our readers, we give their most important points.

Every candidate must not be under twenty nor over twenty-three years of age on the 1st of May in the year in which he is examined. He must produce a certificate of his birth or some satisfactory equivalent of it. He must produce evidence to show that he has passed through the regular course at a recognised college for technical education, and also that he has not been less than three years under training in an approved engineering establishment. Unless his certificates on these points are satisfactory, he will not be allowed to proceed to the examination. About ten appointments will be offered annually for competition among the candidates who fulfil the required conditions; the exact number will be fixed each year by the Lords of the Admiralty.

The examination for this year begins on the 29th of May, and will be held at the Royal Naval College, Greenwich. The following will be the subjects of examination, and the maximum number of marks for each subject:—

I.—Compulsory Subjects.

Statics, Hydrostatics, and Graphical Statics	600
Hydraulics, Pneumatics, and Dynamics	600
Elementary Theory of Mechanism and Machinery	600
Physics. I. (Heat, Light, and Sound)	500
" II. (Electricity and Magnetism)	600
Chemistry	500
Heat and Combustion	400
Steam and Steam Engine	600
Practical Engineering. I.	600
" " II.	600
Workshop Appliances and Practice	600
Mechanical Drawing	400
Total	6,600

II.—Optional Subjects.

Advanced Algebra and Trigonometry	500
Conics and Differential and Integral Calculus	600
Applied Mechanics and Strengths of Materials	600
Metallurgy	500
Design of Machine Details	600
Elementary Thermodynamics	600
Total	3,400
Grand Total	10,000

Candidates who obtain less than 30 per cent. of the marks for compulsory subjects will be considered ineligible for appointment. The eligible candidates will be divided into three classes:—First Class: Those who obtain at least 60 per cent. in the compulsory and optional subjects combined. Second Class: Those who obtain at least 50 per cent. in the compulsory subjects only, but fail to reach the standard of the first class. Third Class: Those who obtain at least 30 per cent. in the compulsory subjects only, but fail to reach the standard for a higher class. Appointments will be made in order of merit from the first class, according to the number which it may be decided to make each year. In the event of a less number than those required being in the First Class, their Lordships may complete the number from the Second and Third Classes in order of merit. Those who pass must be examined by a medical officer to ascertain whether they are physically fit, and produce a certificate of proficiency in practical workmanship from the firms at which they received their training in practical engineering, and another that they are able to swim.

On satisfactory evidence on these points being given, the successful candidates will be entered in the Royal Navy as probationary assistant engineers. Those appointed from the First Class will have the privilege of proceeding to the Royal Naval College, where they will pass through a course of higher instruction along with those who enter from the training college at Keyham. All the probationary assistant engineers will be confirmed at the end of their twelve months' probationary time if their conduct and qualifications are reported satisfactory; and those at the Royal Naval College who obtain First and Second Class Certificates at the final examination at the end of the first session will be allowed to count twelve months and six months of their probationary time towards promotion.

THE COTTON INDUSTRY.

An interesting feature of the cotton trade is the continued success of the Oldham Cotton Buying Company, Limited. This company has offices at Liverpool and Manchester, and buys raw cotton from merchants in Liverpool for spinners, charging the usual broker's commission, but returning, as a rule, 7s. out of the 10s. charged. For the past quarter the net profit declared is £1,515, being 330 per cent. on the capital employed. For some time this company has been a thorn in the side of the old-established Liverpool Cotton Association, Limited, the latter body having "boycotted" the Oldham company. However, the Oldham "limiteds" are supporting the buying company, and it continues to grow in membership and influence. The matter is being at present considered of sending out to the United States a representative to buy cotton direct from the planter. The Board of Trade returns for March respecting cotton goods have a poor look, but when the position is carefully looked into the figures are not really as bad as appears. The decline in our exports is owing partly, if not altogether, to the recent Liverpool dock strike. We venture to state that this month of April will bring up the full average of our shipments for this year. Since the holidays business in yarn has been in rather better demand. The margin, however, is a trifle worse, for whilst raw cotton has definitely hardened in price, cop twist and weft moves upward very slowly. The margin to-day is quite $\frac{1}{8}$d. per lb. worse against the spinners as compared with Christmas. The position, in fact, is that at present selling prices of yarn and cotton an average Oldham mill cannot make ends meet. The outlook, therefore, of the spinning trade is discouraging, and it looks as if the remainder of the cotton season would be adverse to cotton spinners. We have to report that manufacturers are still doing badly. Not only is the demand comparatively indifferent, but the margin between yarn and cloth continues extremely narrow. Altogether the prospects of the cotton trade are discouraging to producers, for, whilst the output of the spindles and looms was hardly ever so large, the margin of profit to the employer is not equal to change for a shilling.

THE RAILWAY AND CANAL TRAFFIC ACT, 1888.

There has just been published by the British Iron Trade Association the statement made on their behalf before the Commission of Inquiry by the Board of Trade on Railway Rates. The statement, with the accompanying statistics, was drawn up by Mr. J. S. Jeans, secretary of the Association, and contains much valuable information. We are only able to summarise it, and this places it to some extent at a disadvantage. The general outcome of Mr. Jeans' statement is that while for long distances the rates are not materially raised—in some cases they are even diminished—the rates for short distances are very seriously increased. Since the bulk of the heavy traffic of the country is conveyed for short distances, this increase of the maxima rates authorised by Parliament is regarded by the Association as inflicting serious disadvantage upon the industries represented by it. The estimate of the cost of transport made by Sir James Allport, and confirmed by Mr. Price-Williams, amounting to ·17d. per ton mile, was quoted by Mr. Jeans in his statement, and an estimate of ·25d. per ton mile based upon it. Taking the cost of transport, then, at $\frac{1}{4}$d. per ton per mile, Mr. Jeans considered that a maximum rate of $\frac{3}{4}$d. per ton per mile for mineral traffic would afford the railway companies a handsome profit.

The practical proposals of the British Iron Trade Association embodied the suggestion that for a 10-ton load the maximum should be $1\frac{1}{4}$d. per ton per mile; for a 50-ton load, 1d.; and for a full-train load, $\frac{3}{4}$d. The general principles of classification which the Association suggested should be adopted are these:—

(1) That no article should be rated higher than it is at present.

(2) Classification means liability to damage or special expense.

(3) Undamageable articles should be all placed in the lowest category, which should be varied in proportion to damageability and costliness of carriage.

(4) The nature of a commodity, its degree of safeness, its easiness of transit, its bulk, its quantity, and its traffic-producing qualities are the considerations that should regulate its classification.

Mr. Jeans states that the average ton mile rate over the whole of Germany is about $\frac{3}{4}$d. per ton mile, while in America it is ·45d. per ton mile. The statistics of these countries show a continuous fall in rates, whereas in our own country, he states that the rates have gone up during the past twenty years. As instances of the effect of the adoption of the proposed classification, Mr. Jeans takes a number of tables, from which we quote the following: The rates for coal and coke traffic on the Great Western Railway for 10 mile distances are proposed to be increased (inclusive of terminal charges) 150 per cent., and for 75 mile distances 24 per cent. The rate for pig iron on the same railway and for the same distances is to be increased by 216 per cent. and 80 per cent. respectively. The rate for bar iron is to be increased 408 per cent. and 136 per cent. respectively. The maxima in each case are of course alone dealt with. Mr. Jeans' calculation is that the proposed classification and increase of maxima will involve the trading community in an addition of £4,000,000 to the cost of transit.

THE LATE MR. WILLIAM INGLIS.

It is with great regret that we announce the death of Mr. William Inglis, engineer, of Bolton, which took place on the 22nd inst., after an illness of only two days' duration. Mr. Inglis was for many years the manager of the engineering department of Messrs. Hick, Hargreaves, & Co., but latterly became a partner in that firm. He received his early training on the Clyde, having been engaged in the works of Messrs. Robert Napier & Sons. He afterwards was for some time in Newcastle-on-Tyne, but about twenty years ago he became connected with Messrs. Hick, Hargreaves, & Co. Mr. Inglis was an engineer of distinguished ability, and at a time when the Corliss engine was a novelty in this country he was largely instrumental in introducing it to steam users. He devoted the whole of his persistent energy to his business pursuits, and undoubtedly did much to improve the construction of the large engines used in textile factories, the reputation always held by Messrs. Hick, Hargreaves, & Co. in this respect having been fully maintained, and even extended, under the management of Mr. Inglis. His sudden death is a great loss in engineering circles, especially in the Lancashire district, where he was well known. His work was not, however, confined to the Lancashire district, for his firm have made and have in hand from his designs the immense engines for the Deptford Electric Light Station belonging to the London Electric Supply Corporation, Limited. These engines alone are a sufficient indication of the great ability of Mr. Inglis as a mechanical engineer, but his skill is further shown in nearly every textile district of the world, to which his firm supplied their excellently made plant.

Mr. Inglis was a man of considerable literary ability, and contributions from his pen have frequently appeared in the technical press. As showing the suddenness of his death, we may say that our issue of last week contained a short contribution from him on a favourite subject.

Mr. Inglis was unmarried, and was 52 years of age. He was modest and unassuming in character, courteous and agreeable in his business relations, but rather of a retiring disposition. Those intimately acquainted with him, however, saw that beneath his quiet reserve there was a firm and persistent will, and, taking him altogether, he was a man of true worth, and his sudden death will be widely regretted.

Letters to the Editor.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

Sir,—With reference to the correspondence now proceeding in your journal on the above subject, I notice that Messrs. Hughes & Lancaster state that it is impossible to obtain reliable data as to the cost of electric traction. I should like to make a few remarks on this point, and mainly as regards traction by accumulators, this system being the most reliable and at the same time the most expensive.

The reason why the Julien accumulator car service was discontinued in Brussels is because the line was a commercial failure, but there were several obstacles in the way of the system being made a commercial success on that line. In the first place, the

Digitized by Google

line was short with heavy gradients; in the second, the cars were small, and, consequently, contained but few passengers as compared with an ordinary sized tramcar; in the third, they were not worked to their fullest capacity; and in the fourth place, the power of the generating machinery was greatly in excess of that required for charging the accumulators, and for leaving ample reserve, it having been originally intended to run ten cars, and plant of this capacity was therefore installed. Consequently, it is not surprising that the undertaking was a failure. Now a totally different state of affairs is shown in the case of the four accumulator cars worked on the Madison Avenue in New York. On that line the working expenses, including maintenance of the accumulators, averaged about 3¼d. per car mile, excluding, of course, the driver's wages. Moreover, several accumulator cars on the Reckenzaun system are running with very satisfactory commercial results in Philadelphia.

It will perhaps be more interesting if I refer in detail to the six accumulator cars now in operation on the Barking line, and with which I am intimately acquainted, although not interested. The cars are worked for the tramway company by the Electric Traction Company at 4½d. per car mile, including the driver's wages, but not those of the conductor, as stated by "Car." When this particular line was worked by horse traction the working expenses per car mile were 6½d., but now the tramway company saves 2d. on every mile run. It is, however, with the working expenses incurred by the contracting company that data are required. The total mileage run since the opening of the line on the 14th June last year to the end of December was 34,366 miles. Now, from a personal knowledge of official statements regarding the total mileage run, the cost of drivers' wages, cost of coal, expenses at charging station, &c., I may state that the line for the period mentioned has been a commercial success. The main point in accumulator traction is the maintenance of the secondary batteries. The cost of renewals in accumulators is estimated by various authorities at from 1d. to 1½d. per car mile, the latter being the highest; but taking 1¼d. as the mean, I find that the profits made for the six and a half months' working of the Barking cars exceed the cost of renewals, leaving the balance for interest and depreciation on the plant. I may mention that Mr. Reckenzaun is now experimenting with an accumulator with which he expects to reduce the cost of secondary battery traction to 3d. per car mile.

With reference to the two cars on the "series" system at Northfleet, only one has for some time been regularly operated, the other being used on busy days. This line was only laid as an experiment, and not as a financial speculation.

Yours, &c.,
F. Baines.

London, 21st April, 1890.

THE FRICTION AND LUBRICATION OF CYLINDRICAL JOURNALS.

To the Editor of "Industries."

Sir,—There is a slight slip in your account of my paper on "Friction and Lubrication of Journals," which I should be glad if you would correct in your next issue. In giving the formula for determining the dimensions of brasses, you have omitted the last part of the expression, which is introduced to meet the case of very high speeds. The formula should stand—

$$\text{Area} = \frac{P\,u\,s}{772}\left(1+\frac{r}{600}\right)$$

where r = the revolutions of the shaft per minute; the value of u has been modified to suit. I also notice a slight slip in the value of u for bath lubrication. Below 100 feet per minute it should be $\frac{0{\cdot}10}{s}$, not $\frac{0{\cdot}12}{s}$. Apologising for thus troubling you,

Yours, &c.,
John Goodman.

The Yorkshire College, Leeds, 18th April, 1890.

THE ADMIRALTY DYNAMO SPECIFICATION.

To the Editor of "Industries."

Sir,—In the remarks under the above heading which appeared in your issue of the 11th inst., you say, dynamo makers are puzzled and discontented with the specification, especially as regards temperature tests and the way they are made. If this be so, the complaint should lie against the yard officers who make the tests, as nothing is said in the specification as to the method of making them. Probably the officers could explain, and make the meaning clear, but before asking them to do so it would be wise to read the specification carefully, without omitting or inserting words which materially alter the meaning,as you have done in your criticism, no doubt inadvertently.

In your opening paragraph you say, "It is specified that after running for six hours with full load, no accessible part of the armature or magnets should have a temperature of more than 20° Fahr.," &c. As a matter of fact, neither armatures nor magnets are mentioned in the clause of the specification from which you quote. You then go on to say that the temperature is taken at the end of one minute after stopping. There is no such statement in the specification. Having assumed a basis which is not specified, you proceed to construct a theory showing what will happen, which is curious if true, although it really has nothing to do with the question of the Admiralty specification.

Is it a fact that any and every machine will have reached its final temperature in a run of six hours with full load? and if this be so, how do you provide a store of heat if, as you say, the heat dissipated is exactly equal to the heat developed? But if it be true, as stated, that the core of the drum is colder on starting, and hotter at stopping, than the conductor, which is the main source of supply, how is the curious result affected by the greater capacity of the core for heat? You next proceed to show that a thermometer applied for a minute, covered with a bit of cotton waste, does not show the temperature of the part in contact. Observe here first that it is not necessary that it should, the condition of contract being that it shall not exceed the stated amount, and as it is not applied in the way or for the purpose you name, both you, and Mr. Willans, might have spared the criticism with advantage to yourselves.

You say the capacity of the thermometer for heat is very considerable compared with the rate at which heat can flow into it. Does this mean that the mercury can swallow up a good deal of heat without increasing in bulk, and if not what has the capacity to do with the result to be obtained? It is sufficient for the purpose of the contract that it shall show whether the amount is greater or less than that stated in the specification. This amount can be known as soon as the temperature of the room is taken. Assuming that in a particular case the room is found to be 100° F., would not a thermometer raised to 130° F. show whether the heat of the part in contact was more or less than this amount, which is all that is necessary to ascertain? You speak of it as taken at the end of a minute, but the instructions are that it shall be taken not more than a minute after stopping.

It is unnecessary to follow the reasoning by which you show that the maximum temperature may be higher somewhere else than where the thermometer can be applied. In the case you suppose, where the lagging or insulation has been removed and the machine run at full load again, you say that the same amount of heat will be generated and dissipated as before. I should have thought that neither would have been the same; that, in fact, the greater rate of dissipation from naked copper would keep the resistance lower and the generation of heat therefore less. This is a sample of the reasoning by which you arrive at the conclusion that the Admiralty are doing their best to select bad dynamos.

You next proceed to show that the exact temperature of the conductor can be readily found by the resistance method. Here we join issue again. A bad joint will affect the resistance test so seriously as to make it quite useless and misleading. Mr. Mordey recently stated that he had known cases where the resistance hot was less than when cold, the test in other words showing that no heat at all had been generated.

You state that ordinary dynamos made in this country have a maximum rise in the conductor of 30° F. in an atmosphere of 120° F. If this be so there should be no difficulty in conforming to the Admiralty specification even if the officers knew how to make correct temperature tests, which you throw doubts on. Some well-known dynamo makers will, I think, be surprised to hear so favourable an account of their work.

We next come to the question of charring, and your remarks would seem to apply rather to the waterproof varnish commonly applied to the fibrous material than to the fabric itself; and if so, the repair cannot be a very serious matter, as a fresh coat can be readily given; but if you mean that the canvas tape, or Willesden paper, commonly used, may soon perish and drop off, the statement is surprising. Mere drying, which takes place at the low temperatures you mention, can neither make them conductors or reduce them to a powder, which can be thrown off by centrifugal force from under or between the bars, without movement in the bars themselves, which should not exist.

Here it may be proper to remark that the Admiralty do not use a temperature test for determining the efficiency of dynamos, and do not apply any test for the purpose of receipt under contract to dynamos apart from the engine. They rely on a simpler and better test, by which they make one contractor responsible for the promised efficiency of both dynamo and engine in pounds of steam per electrical h.p. measured at the terminals of the dynamo. Again, you say, nothing is said in the specification as to whether the machine is to compound accurately in the room where it is tested in Portsmouth Dockyard, or in a 120° stokehold, and suggest a remedy which rests on an error in fact and a misapprehension. The specification does state that it shall compound in the testing room, and the Admiralty never place dynamos in stokeholds. Some of the regulations strike you as curious and even absurd. Perhaps your opinion might be modified by a fuller acquaintance with Admiralty business, such as the necessity of maintaining suitable supplies of such parts as brushes all over the world. You are particularly hard on the requirement of 96 per cent. conductivity copper. Are you quite sure that dynamo makers, honest and respectable as they may be, barring just a few tricks of trade such as you mention, really know that they get the best copper for the slightly higher price? I only know one firm who regularly test it, and should be pleased to hear that they all do.

Yours, &c.,
J. Farquharson.

London, April 19th, 1890.

[Our space is too limited for us to reply to Mr. Farquharson point by point. We wrote carefully, and we do not find anything in Mr. Farquharson's letter to lead us to alter our views. We shall be glad to have the views of some of our readers on this subject.—Ed. *Industries*.]

SUGGESTION FOR A NEW SCOTTISH MAIN RAILWAY SYSTEM.

To the Editor of "Industries."

Sir,—When amalgamation is the question of the hour with Scottish railway companies, the following facts and suggestion may be worthy of attention, namely:—

That it is possible by means of a main line connection, 90 miles in length, to form into one system the systems of the Glasgow and South Western, the Highland, the Callander and Oban, and the Great North of Scotland Railways, whose combined capitals amount to £24,000,000, with a mileage of 1,140 miles.

That in a portion of the line of route (nearly one-half of the total length and in the most barren part) a railway is under or awaiting construction to another part of the country, which might be utilised, and the joint arrangement be mutually advantageous to both interests. The other part of the route is for the most part of the most suitable nature for a line for fast running, being along the level shores of lochs and in straths.

That the route—which would be from Dalwhinnie, on the Highland Railway, to Johnstone, on the Glasgow and South Western, *viâ* Loch Ericht, Tyndrum, Loch Lomond, Leven Valley, and Dumbarton—would be the most direct from Inverness and Oban to Glasgow, Carlisle, and the South. It would also open up more direct communication between the North, North-East, the Western Highlands, the West and South of Scotland, and Ireland.

The crossing of the estuary of the Clyde at Dumbarton by a high level bridge need not be an obstacle as a matter of great cost, the width of the navigable channel being only 800ft. The elevation of the land on either bank of the river is also specially suitable.

That, through the new route, the Glasgow and South Western would have a share of the traffic to and from the North all at present passing along the lines *viâ* Perth and Stirling. The northern companies would also have the privilege of using a line for their South traffic in which they would be directly interested, and would have under their immediate control.

That to the Highland and Callander and Oban Companies especially, such a line would be of the greatest strategic importance, considering the encroachment that is being pushed forward; more so, when the developments which would naturally follow are taken into account.

That by the formation of a powerful company, as in the combination noted, a development of a part of Scotland is possible in a way not at present recognised, but which it is not thought necessary to indicate at present.

Thus, practically, by the addition of only fifty miles to the railway mileage of the country, a new direct route from north to south would be opened up, the amalgamation of four isolated companies made possible, and, in the powerful company which might be formed, a new adjunct created, to the further development of the parts of the country in which the individual systems are situated. The companies interested would be enabled to put themselves in the best position of self-defence against ambitious designs, while at the same time providing themselves with an alternative and more direct route—one, also, in which they would have the greatest interest. Extensions of the systems impossible under existing circumstances would follow the amalgamation and the construction of the new main line.

Would not, therefore, the consolidation of those companies (should neither of the present Bills pass), before they fall as an inevitable prey to their stronger brethren, be for their own benefit, and more to the good of the community and welfare of the country in general than the schemes for the absorption of the most important of them now before Parliament, and which are also being so vigorously opposed?

Yours, &c.,
"Eon Strathaar."

London, 23rd April, 1890.

SMIT'S COMBINED ENGINE AND DYNAMO.

To the Editor of "Industries."

Sir,—With reference to the letter from "Engineer" on the above matter, in your issue of last week, I think that a single-acting engine would have been much more suitable for driving the "Smit Dynamo" than the engine illustrated in your journal of the 11th inst. With a 5¾in. single-acting, single crank, "Silent" engine (working at same speed and pressure), a "smash up" would be far less likely; all the parts would have more than double the area of wearing surfaces, and be better able to deal with the various stresses. A speed of 450 revolutions per minute would be very slow for so small a single-acting engine, as scores of this size have been at work for years at 550 to 600 revolutions per minute without a single "smash up," and without even any adjustments or repairs. I fear that "Engineer's" experience has been with the wrong sort of single-acting engine.

Yours, &c.,
L. Chandler.

Cannock Chase Foundry and Engine Works,
April 22nd, 1890.

THE ACCIDENT TO THE "CITY OF PARIS."

To the Editor of "Industries."

Sir,—With reference to the recent accident to this vessel, will you kindly permit me to call attention to the desirability of having an auxiliary hydraulic propeller or turbine fitted to all large vessels, to act as a last reserve propeller in case of the breakdown of the main engines or screw propellers, and also to act as a very powerful pump in case of collisions, &c.?

In January, 1876, the late Admiral J. C. Wilson read a paper for me on "A Proposed New Combination of Propellers," at the Royal United Service Institution, treating on the centrifugal pump—1st, as a reserve propeller; 2nd, as a most powerful bilge pump; 3rd, as a most powerful fire engine.

Calculations showed that, with a very low efficiency, a centrifugal pump worked by a steam engine of 700 i.h.p. would alone drive H.M.S. "Devastation," of 9,300 tons displacement, at a speed of nearly seven knots per hour, and that it could remove 15,000 tons of water per hour from the ship. And, if only 400 i.h.p. were employed, the speed would be nearly six knots per hour, and the quantity of water that could be pumped out of the ship would be 8,500 tons per hour.

In the paper referred to, I suggested that, in lieu of one pair of engines working one centrifugal pump, it may be desirable to use two or more sets of independent engines and pumps of small power, separated from each other by watertight bulkheads. I know all the objections to the use of the hydraulic propeller, and the difficulties in the way of fitting it on board ship, but it appears to me that, with the high-pressure steam and high-speed engines of the present day, the difficulties are very much less than formerly.

I need not, I think, point out the advantage of having immense pumping power in combination with a small reserve propelling power in our vessels of war in case of injury to the hull or to the main engines during action; but I venture to submit that this is a matter which deserves some attention.

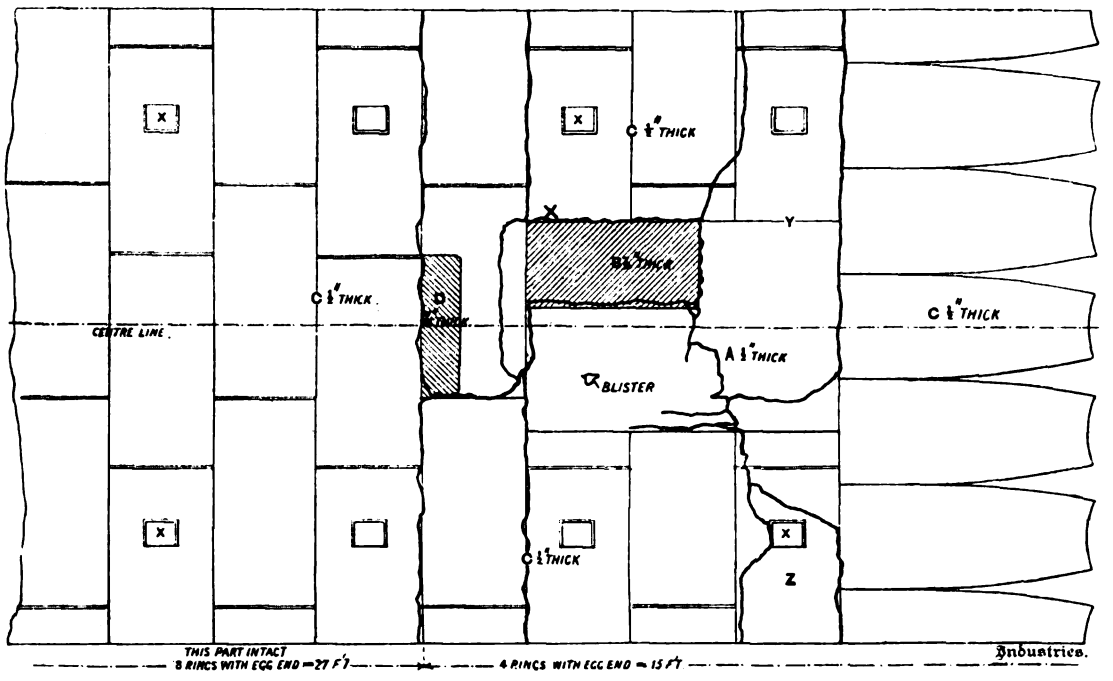
Yours, &c.,
George Quick,
Fleet Engineer, Retired.

Chipping Campden, 22nd April, 1890.

PRODUCTION OF COAL IN JAPAN.

To the Editor of "Industries."

Sir,—Referring to the paragraph in your issue of last week on this subject, permit us to point out that the Miike mines are not now "under Government control," as you state, but belong to our firm.



The Karatsu mines are owned by numerous proprietors—including the Japanese Government—and the name is a general one for a coal district.

Yours, &c.,
Mitsui & Co.

1, Crosby Square, London, E.C., April 22nd, 1890.

THE BOILER EXPLOSION NEAR DUDLEY.

DEVELOPED PLAN OF THE UNDER PART OF BOILER.

THE RECENT BOILER EXPLOSION NEAR DUDLEY.

On Monday, the 13th inst., Mr. Howard Smith, barrister, and Mr. Hallet, consulting engineer, opened a Court of formal inquiry, at the Mechanics' Institute, Dudley, respecting the boiler explosion at the chain and anchor works of Messrs. Noah Hingley & Sons. The accompanying illustration represents a plan looking from the under side of the exploded boiler, the plates being flattened out for convenience of illustration. The boiler was of the egg-ended type, 42ft. long by 6ft. diameter, and fired underneath as usual. It was constructed of best Staffordshire plates, ½in. thick, with double-riveted longitudinal seams, represented by double lines in the illustration, except in a few seams over the fire. The circumferential seams were single-riveted, and are shown by single lines. An unusually large Lowmoor plate A, 9ft. 3in. by 6ft. by ½in., had been put in over the fire when the boiler was made, but it appears that a large piece of it had been cut away at some subsequent period, and another plate, shown at B, 5ft. by 2ft. 6in. by $\frac{7}{16}$in., of ordinary "Lion" brand, had been substituted. This plate should have been "Best Best Lion" or "Best Best Best Lion," as recommended by the makers for positions over the fire. A seam rip, between 2ft. and 3ft. long, had developed in this thin patch, as shown at the mark X, but it is not stated that the boiler gave way at this rip. The portions of plates Y and Z have not been found since the explosion. Another repair appears to have been made at D. The plate here was of "Best Best Staffordshire" brand, 4ft. by 1ft. 4in. by $\frac{7}{16}$in. The supporting brackets are shown at X...X. The boiler had often been repaired, but had not been thoroughly inspected since 1885. Neither had it been subjected to hydraulic tests after repairs. Shortness of water or excessive pressure does not appear from the evidence to have caused the explosion, inasmuch as the boiler is said to have been full of water and the pressure only 45lb. per square inch.

The greater part of Wednesday, the 16th inst., was occupied by the addresses of the solicitors appearing for the several parties interested. Mr. Waldron, on behalf of Messrs. H. & J. Danks, pointed out that both Mr. Hingley and Mr. Danks desired to have the best boiler possible, and agreed that the large Lowmoor plate was desirable, and he contended that the single riveting of that plate was not an element of danger. As regards the suitability of the plate of "Lion" brand used for repairs, he said he was prepared to admit that it was unsuitable for putting over the fire, as applied in this boiler; but because that admission was made, it did not follow that Messrs. Danks supplied the plate. He contended that the actual cause of the explosion was shrouded in doubt. Mr. Mills, an engineer to the Scottish Boiler Insurance Company, had conjectured that the cause of the explosion was a seam rip, but not a seam rip in the "Lion" plate. Mr. Arthur Smith, who appeared for Messrs. Hingley's engineer, considered that the crucial point of the inquiry was the "Lion" plate, the manufacturers of which had distinctly stated that it was unsuitable for placing over the fire, and was not equal to their "Best Best" quality. He contended that there could be no doubt that the plate was put in the boiler by Mr. Danks. As regards inspection, the reason why certain reports of the insurance company with regard to inspection had not been acted upon so quickly as they might have been, was because external examinations of the boiler were continually being made by properly qualified persons. Mr. Thomas Turner, manager of the New British Iron Works at Corngreaves', who had previously given evidence, and stated that "Treble Best Lion" plates were what they should recommend for positions over the fire, said that he trusted no erroneous impression would be created by what had been said regarding "Lion" iron, of which there were four qualities. Mr. Smith, one of the Commissioners, remarked that they were all good iron, but differently wrought.

Mr. Smith, in giving judgment, said that they could not trace when the "Lion" plate had been put in. The Lion brand of plate was made in four qualities:—(1) "Lion," (2) "Lion Best," (3) "Lion Best Best," (4) "Lion Best Best Best." The "Lion," the fourth quality, had been put in to replace a portion of the "Lowmoor" plate, 5ft. by 2ft. 6in., in which edge cracks had developed. On the morning of the 21st March, when the boiler exploded, it had been found sufficiently full of water, and carried 42lb. per square inch pressure of steam. He said they were of opinion that the boiler was properly constructed in 1877, and there was no question that the "Lowmoor" plate was fitted to be used over the furnace. Inasmuch, however, as the longitudinal seams of the boiler were double riveted, they thought that the "Lowmoor" plate that was put in should have been double riveted also. They held that the "Lion" plate, which was put on the "Lowmoor" plate, was not of sufficient quality to be used over the furnace, but he wished it to be understood that they did not find fault with "Lion" iron. The "Lion" iron was of good quality, but Mr. Turner, who represented the company manufacturing the iron, and other experts all agreed that it was improper iron to be used over the fire. Certain tests had been made, but they did not attach any importance to them except to show that the action of the fire rendered the plate brittle. The test given was not that of the iron when it was first used, but Mr. Danks was seriously to blame for employing it. Messrs. Hingley did not appear to have made any provision for a thorough examination of the boiler, and they found that there was never any hydraulic test after repairs. They had therefore come to the conclusion that Messrs. Hingley did not take all reasonable and necessary precautions with the boiler. They also thought that the engineer for Messrs. Hingley should have had more assistance. Messrs. Hingley had repeated reports from the insurance companies stating that their boilers were overdue for inspection. The last time the boiler was thoroughly inspected was in 1886. As regards the cause of explosion, he said that it must necessarily be a surmise. They thought it probably occurred from a rip in a plate over the fire, but there was no evidence to show that the rip started in the patch on the Lowmoor plate. How the explosion occurred they could not say, but the Lowmoor plate clearly showed traces of lamination, and if within a reasonable time prior to the date of the explosion a careful examination had been made lamination would have been apparent, and if a seam rip had existed in the other plate it would probably have been detected, and a lamentable catastrophe avoided. They had no suggestion of blame to make against Mr. Hingley himself, but the firm and their engineer were to blame, as well as Mr. Danks. They assessed the costs against Messrs. Hingley & Sons at £50, and against Mr. Danks at £20.

THE EDINBURGH EXHIBITION.

In our double-page supplement this week we give a general view of the buildings and grounds of the Edinburgh Exhibition, which is to be opened by the Duke of Edinburgh on the 1st of May. We are indebted to Messrs. T. & A. Constable, of Edinburgh, for the permission to reproduce this view.

Since we published our first view of this Exhibition considerable additions have been made to the buildings, and some slight rearrangement of the grounds has been found desirable. The total area now enclosed is about fifty acres. There are eight and a quarter acres of the buildings proper, of which the main building accounts for over four acres, and the machinery hall for about two and a half. The space allotted to exhibitors amounts to nearly a quarter of a million square feet. Compared with recent Exhibitions the present may be said to be intermediate in size between that held in Edinburgh in 1886 and that held in Glasgow in 1888. In several respects, notably in the display of general machinery and the extent and variety of outdoor exhibits and amusements, it will probably surpass any Exhibition ever held in the provinces. There is an electric railway, a line on the telpher system, the Smith ship-railway, and the "Chemin de Fer Glissant" from Paris.

It is not yet time to notice any of the exhibits in their incomplete state, but later on we intend to devote some space to their description in detail. We may mention, however, the splendid display of locomotives, old and new, and a horizontal compound engine by Messrs. Robey & Co., of Lincoln.

Reviews.

BABBAGE'S CALCULATING MACHINES. London: E. & F. N. SPON. 1889.

This is not a systematic treatise on Babbage's Calculating Machines, but only a collection of papers relating to them, as regards history and construction, and is intended to bring together as much as possible the information scattered in various places regarding them, and to make it available for those interested in the subject who may wish to pursue it further. It is not, therefore, a work to be reviewed in the ordinary manner, or, at least, criticised, either as regards matter or arrangement. It is intended to be a mine from which the historian of mechanics may collect information from original sources regarding the work of a man who devoted the greater part of his life to the solution of a mechanical problem. Opinions will, no doubt, differ as to the wisdom of that devotion, but all must admire the perseverance with which Babbage kept at his work, and the ability which he brought to bear upon it. The editor confesses that the arrangement of the book is unavoidably faulty, and promises that if ever a new edition is wanted, that the whole will be recast. The table of contents shows the names of the various papers which have been reprinted, but we do think they might have been arranged in an order more suited to show the development of the ideas involved in the work. For instance, what is the concluding chapter should either have been the first or very near the beginning of the book, as it explains, not only the genesis of the ideas, but also of the steps which were taken for carrying them out, and gives some notion of the sacrifices, both pecuniary and personal, which the invention of the machines entailed upon their author. His son says, however, that few can imagine, and none will ever know, the full extent of these sacrifices. The book should almost be read backwards, for possibly those who are not acquainted with the subject already will find the most easily followed account of Babbage's work in the three last papers, the last one being the one we have mentioned, and the other two a Report of a Committee of the British Association, pub-

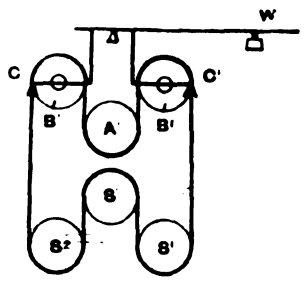
Digitized by Google

lished in 1878, and a paper read by the son of the inventor, and editor of this work, at the Bath meeting of the Association. This latter paper concludes by saying that the writer sees no hope of any analytical engine, however useful it might be, bringing any profit to its constructor, and he adds that beyond the preparation of the paper and the publication of this book there is little or no temptation to do more, as the history of Babbage's Calculating Machines is sufficient to damp the ardour of a dozen enthusiasts.

It is unfortunate that Babbage did not write a complete description of his machines and of the uses to which they might be put. He preferred, while his energies lasted, to devote them to the actual progress and development of the design, although from his book, "Passages from the Life of a Philosopher," published in 1864, and written with the object of interesting the public in these machines, he mentions on the last page a forthcoming "History of the Analytical Engine." This was never carried out, and we have to trust to detached papers for what we know of the inventor's ideas and hopes. Our space will not allow us to enter into details of these. The three papers we have mentioned give the simplest explanation we have seen, both of the principles and methods of using the machines, while that written by Count Menabrea takes up the mathematical side of the subject and gives a most interesting study of it from that point of view. Before Babbage's time many proposals had been made for calculating contrivances of various kinds, the oldest being the Chinese abacus, which is still in use, both in China and Japan. Then we have Napier's rods, and various simple contrivances of the same kind. Pascal invented a very complicated instrument for the simplest arithmetical processes. Leibnitz designed another, which proceeded no further, while various other mathematicians exercised their ingenuity towards the same end. The principle which distinguishes Babbage's inventions from all these is that it proposes to calculate a series of numbers following any law by the aid of *differences;* and that by setting a few figures at the outset, a long series of numbers is readily produced by a mechanical operation. The method of *differences*, in a very wide sense, is the mathematical principle of the contrivance. A machine to add a number of arbitrary figures together is no economy of time or trouble, since each individual figure must be placed in the machine. But it is otherwise when these follow some law. The insertion of a few at first determines the magnitude of the next, and those of the succeeding. It is this constant repetition of similar operations which renders the computation of tables a fit subject for the application of machinery to take the place of the computer. Mr. Babbage set the question to the instrument, or the instrument to the question, and by simply giving it motion the solution was wrought out and a string of answers exhibited. He moreover intended the machine to record its answer, and even multiply copies of it. For an account of the magnitude of the undertaking we must refer to the book. Unfortunately other difficulties besides the mechanical and financial ones intervened, of which some idea may be formed by referring to page 305, but into which we do not feel inclined to enter. We can only say in conclusion that, although the book only appeals to a limited class of readers, it will form a most interesting and valuable addition to the library of the mathematician and the mechanician.

THE PHYSICAL SOCIETY.

At a meeting of this Society, on the 18th inst., Professor Rücker described the results of "Some Recent Magnetic Work," undertaken by himself and Professor Thorpe in connection with their magnetic survey of the United Kingdom. In a paper read before the Royal Society last year they have shown that the United Kingdom can be divided into seven or eight distinct districts, in each of which a source of disturbance seems to exist. The probable cause of these disturbances the authors believe to be the presence of "magnetic rocks." If this be true an intimate connection should exist between the magnetic elements of a district and its geological structure. With a view to testing more fully than heretofore the magnetic constitution of the districts above referred to, the work—the results of which Professor Rücker now described—was undertaken.



Two test districts were selected, in which numerous observations were taken; one of these is situated on the West Coast of Scotland, and the other embraces parts of Lincolnshire and Yorkshire. By the aid of magnetic maps Professor Rücker showed that a centre of disturbance exists to the west of Iona and south of Barra. In the Lincolnshire and Yorkshire district, extending from The Wash to Appleby, there is a region in which the horizontal disturbances along the east side tend towards the west, whilst along the west side they are, on the whole, directed easterly. This points to a ridge of magnetic material along the middle of the region, and from numerous observations the approximate position of the ridge line has been determined over a length of 150 miles. In Lincolnshire the ridge follows closely the line of wolds, whilst at the Kettlewell end it is directed towards the Cumberland Lake District. Places of maximum vertical force occur near Market Weighton and Harrogate. The observers were directed to Market Weighton by Professor Judd, on account of its being situated where the liassic strata thins out. Harrogate stands on the summit of an anticlinal. The fact that such places of maximum vertical force exist where, according to hypothesis, they would be expected, tends to confirm the supposition, and thus to demonstrate that a very close connection exists between the magnetic elements and the geological structure of a country. This is further confirmed by the observation that, in Lincolnshire, the line of disturbance follows closely the line of the wolds, and that from Market Weighton it passes across the plain of York to the millstone grit and limestone, which are the oldest rocks in the neighbourhood.

Mr. T. H. Blakesley read a paper on "A Theory of Permanent Magnetism," by M. Osmond. The author stated that iron exists in two distinct physical states, one soft, or "A iron," and the other hard, or "B iron." The B variety is non-magnetic, and is formed during heating, hardening, or by electrolysis, whilst the soft or A modification is produced by long annealing. In a piece of steel the author considers the B molecules to form a rigid framework in which the A molecules become interlocked under the influence of magnetising force, and on the degree of interlocking the permanent magnetism depends. By a graphical method it is shown that the permanent magnetism should be a maximum when the two varieties are present in equal quantities. If the proportions of carbon and manganese in the steel are considerable, then nearly all the iron is of the B variety and the steel is nearly non-magnetic. In hardening a piece of ordinary steel, the surface layers, being cooled most rapidly, contain more B molecules than the interior; hence, for a certain degree of hardness—when the outer layers have more A molecules than B ones—a laminated magnet will be a better permanent magnet than a solid one, but for a much greater degree of hardness the reverse may be the case.

SOME TESTS ON THE EFFICIENCY OF ALTERNATING CURRENT APPARATUS.*

The apparatus, the measurement of which is the main subject of this paper, consisted of a Westinghouse 750-light No. 1 dynamo, with a No. 2 exciter and an outfit of 40-light converters. This apparatus had been presented by the Westinghouse Electric Company to the Johns Hopkins University, and was tested a couple of months ago. The workmanship of the machines is excellent.

The plant consisted of a 75 h.p. Armington & Sims engine, driving the dynamo and exciter through a Tatham transmission dynamometer. Engine, dynamometer, and dynamos were firmly secured to heavy parallel timbers, which served as a foundation. The converters were banked on a wooden framework at a distance of some thirty yards from the dynamo, and their primaries were permanently secured to the dynamo circuit, a switch in the

latter serving to cut them off when desired. The ammeter belonging to the plant was put in this circuit, and was read when efficiency measurements were being taken. The secondaries of the converters were taken to a switchboard and then to incandescent lamps mounted on racks.

Power Measurements.—The Armington & Sims engine supplying the power worked regularly and satisfactorily, and the governor could be adjusted to give the speed required at the dynamo. The Tatham dynamometer was the one used for power measurements at the International Electrical Exhibition held in Philadelphia in 1884, where its accuracy was checked by making with it a determination of the mechanical equivalent of heat. The result obtained in the latter measurement was 772·8 foot pounds per degree Fahr., and show that the dynamometer is practically accurate. The figure above explains the principle of the dynamometer.

Electrical Measurements.—The energy in the secondary circuit was measured by means of a Cardew voltmeter and a Thomson ampere balance. Each converter had its separate lamp circuit.

Before making an efficiency test, the potential difference in the primary was regulated, and a separate measurement of the potential difference and current in each secondary circuit was made. When the test was actually in progress the voltmeter and ampere balance were used in one of the circuits, and the currents and P. D.'s in the others were calculated from the readings in this circuit together with the previous measurements. Both the voltmeter and ampere balance were accurately calibrated, the former being checked after each test, while the latter had its constant determined with both continuous and alternating currents. The P. D. at the terminals of a non-inductive German silver resistance in circuit with the balance was observed, when a continuous current was flowing, and also with an alternating current of the same period as that employed in the test. The current in each case was calculated from the resistance and P. D., and the results gave no appreciable difference in the constant for continuous and alternating currents.

The following table shows at once the order in which the tests were carried out and the results:—

Horse-power Absorbed at Varying E.M.F.'s.

The efficiency of the converters was measured by placing them in a metal calorimeter, between the double walls of which water was allowed to flow. The temperatures of exit and entrance were observed, as well as the weight of water which passed through; at the same time the current and P. D. in the secondary circuit of the converter were measured. A separate observation gave the radiation, which was of course allowed for although it was made as small as possible. A number of converters were experimented on, but we give but two of them—a 40-lighter, such as was used in the tests, and a 20-light converter, which was very carefully tested by two of the students, Messrs. Bliss and McKeen.

Looking now at the figures given in the tables, we are struck by two things: the very large amount of power absorbed in the core of the armature, and the very small loss in the converters on open circuit. The dynamo losses due to reversals of magnetism and eddy currents at the e.m.f. used in the test are no less than 6 h.p., while the energy due to reversal of magnetism and eddy currents in the 16 converters is only 1·6 h.p. Another rather striking thing is the almost constant ratio of primary and secondary currents over a considerable range.

Suppose we have a plant such as is described above, and use it for commercial lighting. Taking data from one of the local companies employed in supplying incandescent lights on this system we have, for two 2,500-light dynamos, the following outfit of converters:—

Size of Converters.	Capacity.	Number in use.	Total Lamps.
No. 1	5 16 c.p. lamps.	44	220
No. 2	10 ,, ,,	61	610
No. 4	20 ,, ,,	43	860
No. 6	30 ,, ,,	49	1,470
No. 8	40 ,, ,,	64	2,560
Total lamp capacity			5,720
Number of lamps supplied			4,557

The converters being added are of the larger sizes.

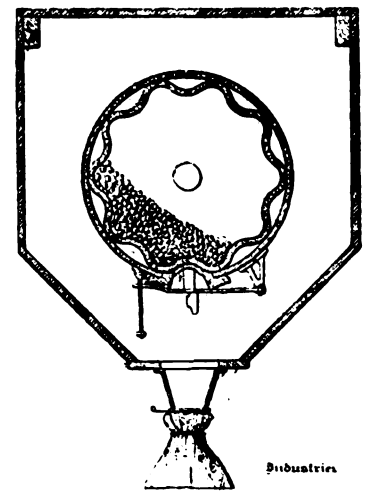

FIG. 6.

To show the disadvantage of the present system for domestic supply, suppose we have an ordinary house, such as one of us would live in; it would be necessary to have a converter of at least 20-light capacity. The constant loss is, say, 100 watts; so, leaving out the C^2R loss, we would have a total loss in 24 hours of $\frac{2400}{24}$, or about 3 h.p. hours, corresponding to, say, 45 lamp hours. Taking my own experience, the actual number of lamp hours used is about 30 lamp hours during 24 hours, so the efficiency of the converter would be something like $\frac{30}{75} = 40$ per cent. It is evident that, unless the losses in converters can be greatly decreased, a house-to-house distribution with a converter in each house would hardly pay.

It would seem, then, that if gas is to be really displaced, and serious competition with it is to be attempted, a different system of distribution must be worked out. We must replace the numerous small converters with one large converter supplying a comparatively extended district, thus decreasing the converter capacity, since the law of average can be taken advantage of, and greatly increasing the efficiency. If an extended secondary network is employed, some of the converters may be disconnected from the mains at the turn of minimum demand.

Probably, many of us have seen Mr. Swinburne's paper, which was read before the British Association last year, on the "Design of Converters," and have been struck by the fact that almost all of the converter dimensions given by him are impracticable, either on account of the disproportionate heating of the larger sizes, or the excessive fall of potential in the secondary. In increasing the size of dynamos we usually increase the output per pound weight, but there is the vital distinction between dynamos and converters that losses occur through the entire mass of the latter, and as we increase the volume we increase the losses in the same proportion. In the dynamo, on the contrary, there are practically no losses in the heaviest part of the apparatus —i.e., the field magnets. As a result, while we gain in efficiency in the larger sizes, yet we must decrease either our induction or the rate of reversal, and the output per pound is not increased.

THE MANUFACTURE OF PORTLAND CEMENT FROM SLAG.

In our issue of the 7th of February we gave an abstract of Mr. Gilbert Redgrave's paper on the utilisation of slag, read before the Society of Arts in the beginning of the year, and in which it was pointed out that the manufacture of Portland cement from basic slag sand is one of the more important methods of utilising this waste product. We said then that the system of cement testing used in this country militated against this cement having a fair trial in England, but we are glad to notice that contractors are beginning to imitate France and Germany in using this new cement, especially for making sea-walls and other works in water. We illustrate on pages 402 and 403 the plant necessary for the manufacture of this cement, and now give a brief outline of the mode of manufacture. A good Portland cement made from slag consists of an intimate mixture of granulated slag and about 25 per cent. of lime, reduced to a very fine powder by mechanical means. Early in the manufacture of this cement it was pointed out by Mr. C. Wood, of the Tees Ironworks at Middlesbrough, that a preliminary granulation of the slag was absolutely essential for the preparation of a satisfactory cement. This granulation appears to bring about both chemical and physical changes in the slag, causing the silica and alumina present to attain a condition of readiness to combine with the lime which is subsequently added, and when examined under the microscope the granulated slag is found to contain clear and brilliant grains imbedded in the matrix instead of the dark aggregates which are characteristic of the original slag. In fact, it is possible by a microscopical examination to judge of the value and completeness of the granulation process by noting the relative proportions of these two kinds of appearances, and it is customary to reject as unsuitable for the preparation of a hydraulic mortar those granulated slags which show a preponderating number of black granules. Early experiments also established the fact that the basic slags such as those obtained in the basic steel process were only suitable for this manufacture, and at present, even by largely increasing the percentage of added lime, the almost neutral and acid slags have not been rendered available for cement making. In calculating the amount of lime to be added, it is found that when the ratio of the sum of the oxygen in the silica and alumina of the slag to the amount of oxygen in the added lime is as 2:1 then the best quality cement is obtained. According to Tetmajer, when the ratio of lime to silica in the slag is less than one, then the slag is unsuitable for this manufacture. In those slags which contain an appreciable quantity of calcium sulphide this substance must be regarded as equivalent to so much lime present, since in the process of granulation it is decomposed by the water thus:—

$$CaS + H_2O = CaO + H_2S.$$

As pointed out by Mr. Redgrave in the discussion which followed the reading of his paper, the presence of calcium sulphide in the slag is of very small importance, as up to 3 per cent. it produces no injurious effects upon the quality of the cement, except rendering it slightly slower in setting. Sometimes it is found necessary to add, in addition to the lime, some gelatinous silica and alumina, both of which can readily be obtained from some unused slag by treating it with hydrochloric acid and filtering off the insoluble silica, when the alumina can be precipitated from the filtrate by the addition of lime. The additional alumina is also sometimes obtained from sodium aluminate obtained by fusing bauxite with soda.

In Figs. 1 and 2 are shown one of the forms of plant employed in Germany for converting the quicklime into dry slaked lime. It possesses the advantages of being very convenient for regulating the quantity of water to be added, of lessening the amount of hand labour, and preventing the formation of dust, which is so injurious to the workmen. The lime in coarse lumps is placed in the receiver Q, which rests on rollers and is enclosed in the larger cylindrical vessel P. This vessel P can be closed at S after the lime is introduced, L being a safety valve and pressure gauge to record the pressure, which may rise to 80lb. or 90lb. per square inch. The water is introduced by opening a cock which allows the water from a reservoir to flow down O into the pipe K J, which distributes the water uniformly over the lime. After remaining in the apparatus for some little time, the heat generated by the slaking causes the excess of water to pass away from the lime and condenses on the walls of the containing vessel, so that on removal the lime is found to be completely slaked and in the form of a dry powder ready for mixing with the slag.

The granulated slag often contains from 15 to 30 per cent. of water, and before being used it is necessary to remove this water by drying. The simplest method consists in exposing the slag in a thin layer on a hot plate,

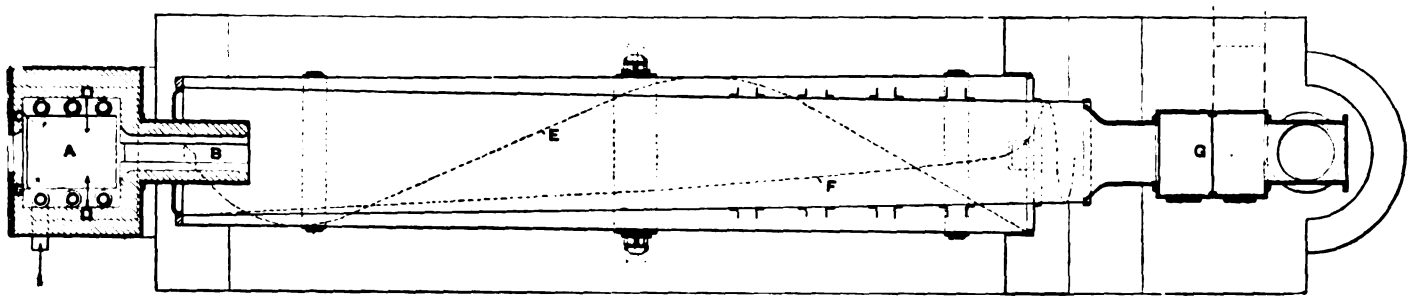

FIG. 7.

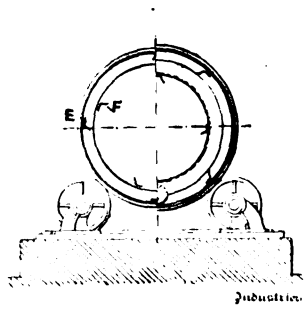

FIG. 8.

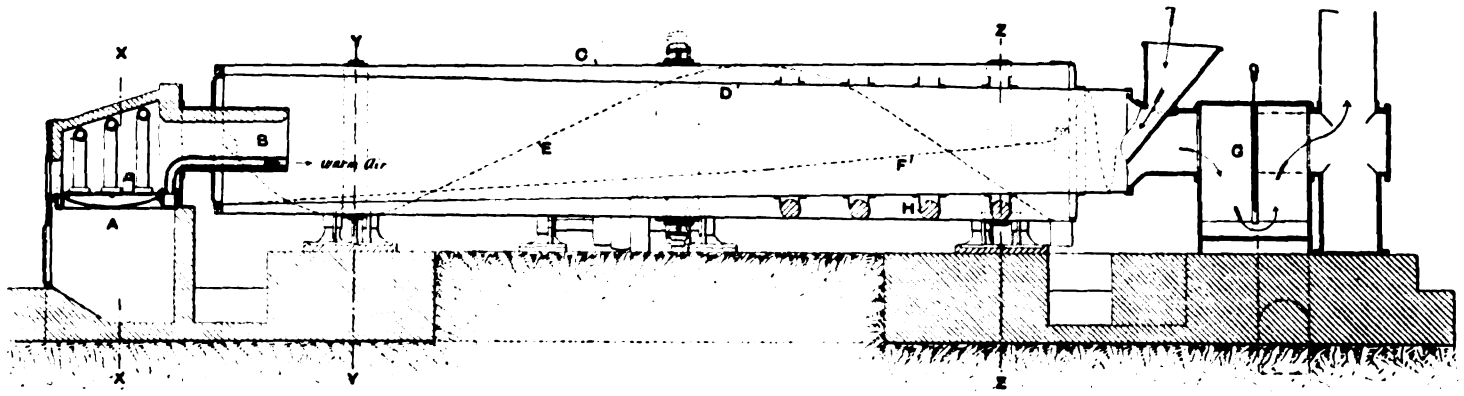

FIG. 9.

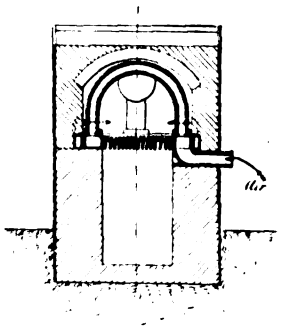

FIG. 10.

and it is possible to dry completely 100 kilog. per square metre of surface per 24 hours in this way, with a consumption of 6 to 7 kilos. of coal. There is, however, a good deal of handling and labour attached to this method, and many processes are in use which are more or less continuous in action and more economical in labour and fuel. The drying apparatus devised by Ruelle, and used in France in the phosphate industry, has been used with success for drying granulated slag. We illustrate this apparatus (Figs. 7, 8, 9, and 10), which, it will be seen, consists of a long rotating cylinder containing the slag, and through which a current of hot air circulates. At A the air is heated, and at B it enters the cylinder, through which it it is made to circulate by means of a ventilator. The rotating cylinder consists of two long slightly conical columns about 10 metres in length. The internal cone has its base nearest the fire, and is fitted with four helices, which regulate the motion of the slag within, so that it is uniformly exposed to the drying action of the hot air. The outer cone has its base away from the fire, and is supported at Y and Z, and within has four friction rollers on which the internal cone rotates. With this apparatus 25 tons of slag can be dried in 24 hours with an expenditure of 6 kilos. of coal per 100 kilos. of slag for heating the air and a motive power of 6 to 7 h.p. The apparatus, with ventilator, costs between £500 and £600. Other methods of drying the slag are in use at Choindez, in Switzerland, and at Saulnes, where recently M. Raty has erected important works for the manufacture of cement from slag. In the process patented by M. Raty the slag is granulated and dried in one operation. The apparatus is illustrated in Fig. 3. The slag, as it issues from the furnace in a molten state, flows down a metal channel, which is cooled by water (from T_2, T_4, and T_6) on the outside, and at the same time comes in contact with a small quantity of water (from T_1, T_3, T_5) within. It will be seen that in this method the cooling must be so regulated that the slag becomes hard and granulated, and also sufficiently porous, before it reaches the end of the inclined plane, and at the same time must not prevent the evaporation of the water from the pores of the slag, so that it may be delivered in a dry condition on to the metallic running band. The length of the channel depends on the nature of the slag. M. Grosclaude, to whom we are indebted for this description, does not state whether the process is one which has come up to the expectations of the patentee. It seems to us that when once the proper dimensions for the successful delivery of the slag in a suitable condition for cement making at the bottom of the channel are obtained, the process should be one of great value, but we are unable to say whether the inventor is prepared to give data for these dimensions for varying amounts of slag. Fig. 4 shows a section of an air drying arrangement in use at some works.

After the slag is granulated and dried it is next ground to a fine powder in an ordinary mill. It is then ready for mixing with the requisite amount of dried slaked lime, which operation is effected in a specially constructed ball mill. We illustrate in Figs. 5 and 6 the mill, which is constructed by Luther, of Brunswick, for this purpose. It consists of a cylinder which can be rotated about a horizontal axis, and containing a large number of metallic balls about 25–35mm. in diameter. The mixture of lime and slag is added by means of a screw feeder below the hopper. When the cylinder is nearly full, it is set in motion for about two hours, when the lime and slag are not only intimately mixed but reduced to an exceedingly fine powder. By an opening in the side of the cylinder the contents can be emptied into a bag placed for the purpose, a grating preventing the metal balls from falling with the powder into the bag. Other mills for this purpose have been constructed by Thivet-Hauctin, of St. Denis. M. Grosclaude concludes his description by giving an estimate for the cost of erection of an installation for the manufacture of cement from basic slag. He estimates that to produce 20 tons a day, or 6,000 tons per annum, the necessary outlay in plant, consisting of a Ruelle dryer, an engine of 150 h.p., a furnace, and all necessary mills, grinders, and mixers, as well as bags and barrels for holding materials and finished product, would be about £6,000. His estimate for cost of production, including labour and fuel, and interest on capital, is 18·584fr. per ton of cement; but he further adds that this estimate is probably much too high, and states that in France, in those ironworks which have erected cement-making machinery for utilising their slag, the cost of production does not exceed 12fr. per ton. As the selling price of cement in France is about 35fr. per ton, this shows that a considerable profit can be made out of this industry.

THE SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

ON the 21st inst. Mr. Boverton Redwood communicated a paper on "The Indian Oil Fields," in which he reviewed our present knowledge of the extent of the oil-bearing districts in India and Burmah. He pointed out that, in addition to the oil fields of Upper and Lower Burmah, a large oil-bearing area existed in Assam, and that recently the Indian Government had made considerable progress in the development of wells in the Punjab and Beloochistan. The Lower Burmah deposits have been known for many years, and have been described by Mallet, Mendicott, and others. The chief centres are the islands of Ramri and Cluduba, and with proper methods of well-sinking there is no doubt that they would form the centre of a large industry. It is to be noticed, however, that the oil, which is dark brown in colour, is very variable in quality, that from East Baranga having a sp. gr. of ·835, and that from West Baranga being much heavier (·888). A still lighter oil (sp. gr. ·818) is obtainable from the mud volcanoes, and it can be burnt without previous distillation.

The Upper Burmah oil, which is shipped from Rangoon, and often known as Rangoon oil, has also been utilised by the natives for many years. It is a very viscid, almost solid, oil, of a dark brown colour, and contains a very large percentage of solid paraffin. Dr. Noelting, in his report of last year, draws attention to the fact that the district is of tertiary age, and that the oil-bearing sands belong to the miocene period. The oldest wells lie in the Yenangyoung district, but recently the newer fields of Twingoung and Beme have been opened up on either side. Messrs. Findlay, Hannay, & Co. have engaged American drillers, and their operations have so far shown that even at depths of 400ft. there is sufficient oil to yield a remunerative return to the capital invested, while there is no doubt that at greater depths further and larger finds of oil will be made. The Twingoung oil field has an extent of ninety acres, in which, according to Dr. Noelting, there are 375 wells, of which 120 are productive, yielding 80 to 90 riss per diem. The greatest depth of these native-dug wells is only 300ft., and considerable difficulties have to be encountered in sinking the well by manual labour, as the petroleum vapours prevent the workmen from being below for longer than 290 seconds. The author pointed out that these wells were not ventilated, and that although in Galicia efficient ventilation in the well-digging operations was compelled by law, and in Japan a blowing machine was invariably employed, yet the British Government had not as yet taken any steps towards preventing loss of life in these undertakings.

In the Beme oil field of 35 acres there were 151 wells, of which 72 yielded between 50 and 70 riss per diem. Messrs. Findlay, Hannay, & Co. commenced drilling operations in 1887 in this district, and have now nine drilled wells in their possession.

The following table gives the character of six samples of oil from the Yenangyoung district:—

No.	Sp. Gr.	Flashing Point.	Setting Point.
1.....	·887	110° F.	82° F.
2.....	·937	150°	below 0°
3.....	·869	62°	80°
4.....	·870	80°	78°
5.....	·873	83°	82°
6.....	·837	80°	60°

Digitized by Google

It will be seen that the oil may be divided into two classes, No. 2 being distinguished by its high specific gravity and flashing point, the absence of any large quantity of solid paraffin, and its high viscosity, while No. 5 is an oil which gives a good kerosene on distillation and about 12 per cent. of solid paraffin.

It has further been noticed that, contrary to experience elsewhere, the wells of greatest depth do not yield the lightest oils, and at present a good deal of uncertainty prevails as to the kind of oil which any particular boring is likely to furnish. At Rangoon, belonging to the Burmah Oil Company, is a large refinery capable of distilling half a million gallons of oil per month, which is more than sufficient for the present requirements. The high temperature at Rangoon renders the refining process a difficult one, and it has been found impossible to manufacture any products from the solid paraffin obtained, which is therefore sent to England in its crude condition.

In the Pagan oil field, in Upper Burmah, the production is diminishing, and at Mindu, where the oil has never been commercially worked, drilling operations are now in active progress.

In the Assam district the author pointed out that, since 1860, when Goodenough obtained a concession to sink wells, and finally struck oil at a depth of 118ft., a good deal of progress has been made. The difficulties of transport are gradually being overcome, and the Assam Railways and Trading Company are now pushing on well-sinking operations in some of the best concessions in the district.

At Digboy oil has recently been struck at a depth of 275ft. in soft sandstone overlying shale, but the yield, which was at first 80 barrels a day, has since diminished. In the Punjab, at Rawal Pindi, there are at present sixteen wells, and the concession for this locality has been secured by Mr. Noble, of Canada. Mr. Townsend, on behalf of the Indian Government, has been recently engaged in prospecting in the Khatan district, where there are now five wells sunk to a depth of 500ft. The strata there dip at a considerable angle, which presents some little difficulty in ensuring a vertical drilling of the well. The oil has a very high specific gravity, due to asphaltum, and it is difficult to separate it from the water with which it is mixed. The supply is, however, practically inexhaustible, and as the district is one in which fuel is scarce, the importance of this liquid combustible in the district cannot be over-estimated, being situated, as it is, in the direct line of our railway system towards Kabool and Afghanistan. The climate of the district is unfortunately bad.

In conclusion the author gave as his opinion that of the Indian earth oils, the best for the kerosene refiner is that obtained from the island of Ramri, off the coast of Lower Burmah, while that obtained from the Yenangyoung field gives the best yield of solid paraffin. The author has lately, in conjunction with Professor Dewar, devised a method of treatment for this Yenangyoung oil which will considerably increase the yield of burning oil.

NITRIC ACID CHLORINE PROCESSES.

At the opening of the Manchester Permanent Chemical Exhibition, on Tuesday, the 15th inst., Mr. G. E. Davis read a paper on "The Process for Making Chlorine by the Reaction of Hydrochloric on Nitric Acid," recently patented by Mr. William Donald.

He first referred to the history and progress of chlorine making and the previous attempts which had been made to prepare it by the process under notice. The great difficulty had always been to get rid of the water which was produced in the reaction. No success had been obtained until 1885, when Taylor's process was patented. In this process hydrochloric acid is introduced into a vertical cylinder or tower containing coke or pumice soaked in strong nitric acid, whereby chlorine, nitrogen tetroxide, and water are formed. The products are passed into a similar cylinder containing pumice soaked in strong sulphuric acid, whereby the water and nitrogen compounds are removed with the formation of nitrosyl-sulphate, while the chlorine passes on and is absorbed in lime. Ninety-six per cent. of the hydrochloric acid used is decomposed into chlorine. The process, however, for various reasons, did not prove a complete success. In 1887 Mr. William Donald patented his modification of the process, which has now satisfactorily passed its trial stages, and promises great things in the future. In this patent the hydrochloric acid is taken direct from the salt-cake pan by suction. It is passed through nitric acid, and the evolved gases are sent through a cylinder containing strong sulphuric acid, and then again through nitric acid. Finally the chlorine is passed through sulphuric acid and is then absorbed by lime. It is very important that the reaction should take place at a low temperature, and therefore cold brine at 0° C. is kept in circulation round the cylinders by a pump. Mr. Donald expressed the reaction as follows:—

$$(1)\quad 2HCl + 2HNO_3 = 2H_2O + N_2O_4 + Cl_2.$$
$$(2)\quad N_2O_4 + H_2O = HNO_3 + HNO_2.$$

The reactions are the same in both processes described, the difference being in the arrangement of the plant and the method of working.

Notes.

A RAILWAY THROUGH PALESTINE.

A COMPANY is being promoted in America to be called the New England Land Company of Egypt, the objects of which are the development of the port of Alexandria and the construction of a railway through Palestine, *viâ* Hebron, Jerusalem, Jericho, Nazareth, and Galilee to Damascus. It is expected that the tourists to the Holy Land will profitably maintain a first-class modern railway.

ELECTRICITY IN JAPAN.

DURING the past few years the applications of electricity have made great progress in Japan, there being now five large companies carrying out the lighting of buildings, &c., from a central station. The stations at Tokio, Kioto, Kobe, Osaka, and Nagoya are stated to have lighting power for 22,300 lamps, 11,000 of which are said to be in use. Besides these ten other companies have received permission to erect works at Nagano, Kumamoto, Nagasakai, Hakata, Yokohama, Hiroshuna, Shidznoka, Hukodate, Niigata, with a total power of 16,800 lamps. The first company was established in Tokio in 1886.

THE STANDARD OF LIGHT.

THE London County Council have adopted the recommendation of their Sanitary and Special Purposes Committee to take immediate steps for the legalisation of a better standard of light and a standard type of photometer. Their letter to the Board of Trade last year was rendered abortive, mainly, no doubt, owing to their wish to introduce the portable photometer as a legal instrument. We hope that, by dropping this part of their former programme, their action will result in the long-wished-for dismissal of candles as the legal standard. We are confident that, with this alteration, most of the difficulties attending photometric measurement of light will disappear.

CHINESE GOLD MINES.

CHINA is no doubt progressing, though the rate of advance is slow, and it is always something when the Chinese themselves recognise that they might be doing better. A native paper at Shanghai draws attention to the question of gold mining in the empire, and points out that the Pingtu gold mines on the promontory of Shantung have failed to be remunerative on account of bad methods of working. At the Amur gold mines a better state of things exists, the local authorities having set to work to exploit them energetically, but it does not appear what machinery, if any, has been obtained. These latter mines lie on the Russian frontier, and at present are difficult of access, but new roads are to be opened up, and a steamer service organised.

THE CORINTH CANAL.

IT is eight years since the King of Greece cut the first sod of the Corinth Canal, and there is now a fair prospect, notwithstanding all the difficulties, financial and otherwise, which have come in its way, of the work being completed in about two years more, as a Bill granting a concession to a Greek company to carry on the work has been read a third time by the Chamber of Deputies. The new company is authorised to raise 5,000,000fr. capital in shares, and 15,000,000fr. by loan. The original contractors formed an over-sanguine estimate of the cost of the work, and came to a deadlock last year over arrears of payment. When the canal is completed, it will have cost at least £3,000,000, which is a considerable sum for a length of about 3¾ miles. It is intended to provide a navigable channel, 28ft. deep, 52ft. wide at the bottom, and 93ft. wide at the water level, and the advantages which it will offer to commerce will be considerable, affording, as it does, a short cut from the Adriatic to the Ægean, and saving all the perils of navigation around Peloponnesus. When it has been completed, we may yet see Corinth regain much of that commercial repute as a port and a centre of commerce which at one time made it so prosperous.

RUSSIAN INFLUENCE IN PERSIA.

FOR some time past there has been a considerable struggle for ascendency in Persia between the British and the Russians, not only in matters political, but also in those relating to industrial enterprise. The latter race have received some important concessions recently. It has apparently been arranged that the Russian Government shall receive notice of all projected Persian railways, and that Russian capitalists shall always get the refusal of railway concessions. A recent telegram from Vienna states that in accordance with this agreement an agent of the Persian Government will shortly arrive in St. Petersburg to begin negotiations with Russian financial houses for the construction of roads and railways in Persia.

PUBLIC COMPANIES IN SCOTLAND.

FROM a return recently published in the *Scotsman* we learn that in one week forty new joint stock companies have been registered in Scotland, with a total capital of £3,455,820. The capital of the 136 companies registered throughout the year 1889 was £8,844,604, which, however, included a number of private firms converted into limited liability companies, whose shares were not offered to the public. The largest individual share capital of the companies registered during the first quarter of 1890 was £700,000, being the businesses now amalgamated under the name of A. & T. Stewart, Ld., and made up of manufactories for pipes in iron and steel, and of works for the production of steel. Five shipping companies and two paper mill companies had been started, while two more breweries were converted into limited liability companies during the first quarter. A new gold mining company for Australasia has been formed with a capital of £250,000, and a coal company has been floated with £500,000 capital.

THE BELL ROCK LIGHTHOUSE.

THE effects of the recent explosion at this lighthouse have been repaired, and it is again in working order. As this is the first time the light has been interrupted since the lighthouse was erected, the accident has attracted considerable attention, and a question was addressed to the President of the Board of Trade in the House of Commons. From his reply, and from the published reports, it appears that the explosion was due to a neglect of the instructions issued to the keepers along with the fog signal. These provide for the signal being fired only at a due and safe distance outside of and above the lighting apparatus, and if they had been observed the disaster never could have happened. It must be admitted, however, that the instructions to the keepers are of a somewhat complicated nature, and the man in charge seems to have got confused and to have exploded the charge inside the light room with the disastrous results already known. The President of the Board of Trade has intimated that the Commissioners of the Northern Lighthouses have asked their engineer to report whether such modifications cannot be made on the apparatus as to render another accident impossible, and we have no doubt that this can easily be done. Accidents of this kind should always be utilised for the purpose of marking the limits of safety.

OXYGENATED OIL GAS.

DR. THORNE, of the Brin's Oxygen Company, has recently carried out a series of experiments with the view of testing the advantages of the Tatham patent for the manufacture of an oil gas of very high illuminating power. It will be in the recollection of our readers that Mr. Valon has shown, at Ramsgate, that oxygen may be used with advantage for the purification of coal gas, and that he found that in his process the addition of oxygen to the gas caused an increase in the illuminating power. The same is now found to be the case when oxygen is added to oil gas, and it has been shown that as much as 50 per cent. of oxygen can be added to the oil gas without any risk of forming an explosive mixture. The process at present used at the Brin's works at Westminster consists in first heating American petroleum to a moderate temperature in an iron retort, and then adding to the gases and vapours produced about 20 per cent. of oxygen, which prevents the subsequent condensation of the vapours and at the same time enormously increases the illuminating power. The necessary plant is of a very simple description, and, as far as one can judge from the experiments which have been carried out, there seems every ground for believing that the process is one which will be found to work well on a large scale and be capable of producing an illuminating gas of high intensity at a comparatively cheap rate.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

8th April, 1890.

5289. Adair, T. ..... Scutching flax.
5291. Andrews & Berry ..... Protecting steel ropes.
5295. Dunsmuir, H. ..... Cranked shafting.
5301. Black, J. B. ..... Scutching machines.
5308. Nelson & Shaw ..... Mules.
5315. Jones & Jones ..... Impressing and printing wood.
5319. Lewthwaite, J. ..... Improving quality of iron.
5323. Burkhardt & Jackson ... Forming ornamental tubes.
5325. Grill, L. ..... Pumps.
5326. Haddan, R. ..... Train and locomotive (*Weigel*).
5328. Haddan, R. ..... Railroad switches (*Crepel*).
5330. Anderson, C. ..... Machinery for making paper bags.
5336. Brigham, M. E. ..... Box making machines.
5339. Grosselin, H. ..... Fulling machines.
5343. Lake, H. H. ..... Telpherage (*Maynadier*).
5345. Lake, H. H. ..... Manufacture of screws (*Russell and Erwin Manufacturing Co.*).
5350. Schütz, C. ..... Reducing valves.
5352. Cottrell, C. B. ..... Printing machines.
5355. Martin, W. E. ..... Utilising tides for producing motive power.
5358. Skinner, G. J. C. D. ... Slide covers of cylinders.
5361-2. Gaines, Pickens, & Gaines ..... Car couplings.
5365. Imray, O. ..... Steam pumps (*Irrigation Pump Company*).
5371. Leslie, R. D. ..... Stuffing boxes (*Leslie*).
5374. Nisbet, W. R. ..... Holding gear for ships' boats.
5378. Jensen, P. ..... Pneumatic buffer (*Riegel*).

9th April, 1890.

5383. Hamilton & Young ..... Torpedo booms.
5389. Houlden & Morris ..... Steam engines.
5393. Cameron, D. ..... Steam boiler (*Battin*).
5394. Cameron, D. ..... Car brake (*Brunquest*).
5396. Nittinger & Rotter ... Railway brakes.
5397. Whitfield, C. ..... Punching and eyeletting machine.
5398. Czischek, L. ..... Valve gear.
5402. Ockendon, W. ..... Shaping boiler plates.
5404. Grey, E. H. ..... Flying machine.
5408. Paulitschky, C. W. ... Machine for removing snow from railways and tramways.
5410. Lishman, T. G. ..... Boiler furnaces.
5415. Horn, W. W. ..... Brick machine (*Grant & Murray*).
5424. St. John, S. H. ..... Starting and moving cars.

10th April, 1890.

5427. Ibbotson, E. C. ..... Railway buffers.
5429. Tattersall, W. ..... Air compressor or blower.
5430. Williams, H. ..... Gas engines.
5431. Williams, H. ..... Riveters, punches, &c., worked by gas engines.
5432. Williams, H. ..... Governor for gas engines.
5433. Williams, H. ..... Governing admission valves of gas engines.

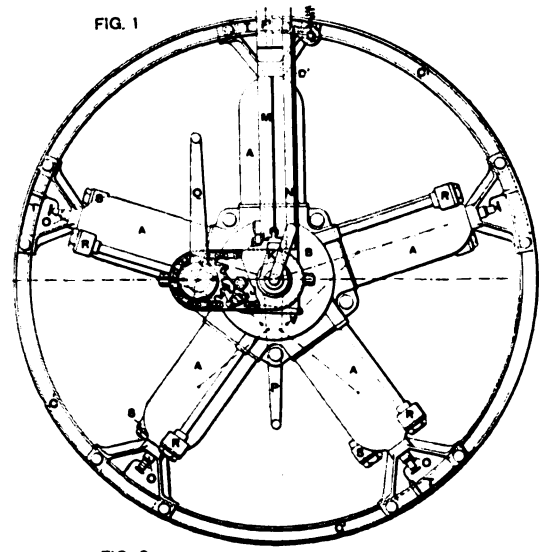
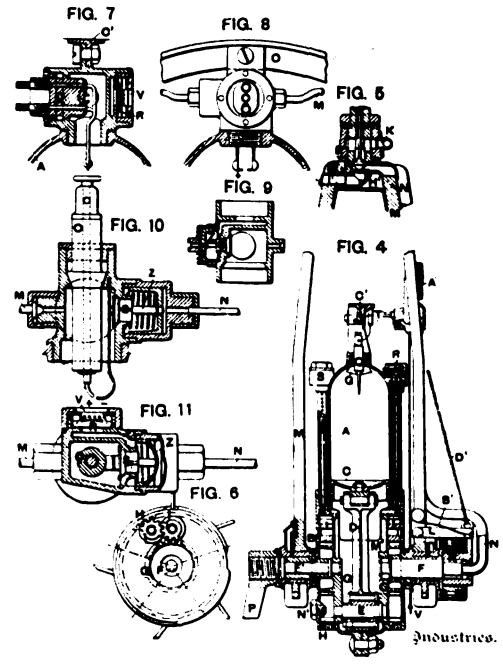
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.



ENGINEERING.

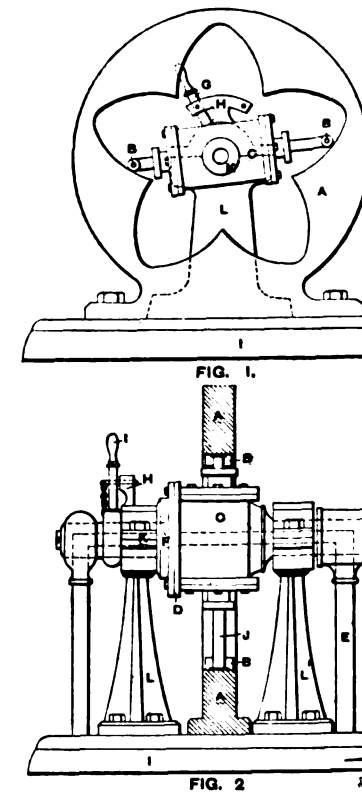
Ships' Propellers.—*H. C. Vogt, Copenhagen, Denmark.*—The two blades of the propeller are each formed with or rigidly connected to a short cylindrical part or axle which is secured in a boss upon the propeller shaft, with its axis at right angles to the axis of the shaft. The blades are capable of turning about the axis of these axles, and thus when the propeller is at work it will only be in continual equilibrium when the greater part of its acting area is aft the produced axis of symmetry through the axle. When the propeller is rotated in the following currents of the ship, the pitch angles of the blades will continually change equally but in the opposite sense, whereby the forces acting on the blades will continually balance each other so as to permit the blades to be broadest near the circumference. Heavy strains are also avoided, such as are usually caused by the pitching of the ship. When the engine is reversed the propeller will of itself turn 180° to be in equilibrium, and makes the blades as effective in driving astern as ahead. Claims: (1) A two-bladed propeller in which the blades are rigidly connected with each other by a blade axle which is able to move in, and enclosed by, the boss like a shaft in a bearing, thus enabling the thrusts on the blades to balance each other in the following currents of the ship, whereby vibrations are avoided without tapering the blades; (2) in a two-bladed propeller of the character described, the employment of a yielding stop or spring for the purpose of making the oscillations of the propeller in the following currents of a ship as elastic as possible with minimum of oscillation to annihilate vibrations; (3) the construction of two-bladed propeller as illustrated in the specification. —No. 7738. May 8th, 1889. 6*d.*



Vacuum Pump.—*E. F. Varaldi, Paris.*—This pump is especially applicable for exhausting bulbs of incandescent electric lamps. On a horizontal axle, which is formed with ports like the plug of a cock, is mounted two tubular arms, more than 30in. in length, and to whose outer ends are jointed vessels having their tops connected by a rod pivoted to them. This rod is mounted on an axle above that on which the arms are mounted, so that it is always parallel to the arms when they are caused to oscillate on their axles, and the vessels at the ends of the arms are thus always maintained in a vertical attitude. The vessels are charged with mercury, and the ports in the plug axle communicate with a vacuum tube, to which are attached the bulbs or other vessels to be exhausted. When the tubular arms are caused to oscillate on the plug axle, the mercury flows down the one arm away from the axle, creating a vacuum, and a port being then open to the vacuum tube air is drawn from the tube into the arm. The mercury in the other arm flows down towards the axle, and the port to the vacuum tube being closed the air previously drawn into this arm finds its way out through the mercury. Thus by oscillating the arms, and so displacing the mercury in them through a height exceeding 30in. at each oscillation, there is formed in each arm alternately a torricellian vacuum next the axle, into which air is drawn from the vacuum tube, and from each arm alternately the air drawn in is expelled. It is preferred to enlarge the cavity of each arm near the axis, so as to have the vacuum formed in considerable space. Claim: A vacuum pump constructed and operated as described.—No. 8687. May 24th, 1889. 6*d.*

Winding Yarn.—*H. H. Lake, London.* (*W. H. Goldsmith & J. H. Wright, Massachusetts, U.S.A.*)—The invention consists in a spool-holder or bobbin-holder which is adapted to be mounted on a winding machine, and is arranged so that it can slide or move towards and away from the mechanism for rotating the spool or bobbin mounted in the holder. This spool-holder is composed of two arms, which are connected with each other by a bar so as to form a frame having substantially a U-shape. Near its upper end one of the arms is furnished with a rod or stud, preferably made adjustable on the arm both up and down and in and out, and the other arm is provided with a rod or spindle loosely mounted in the arm so as to be capable of an in-and-out motion. These two rods constitute the bearings or centres to receive the spool or bobbin and hold it so that it can be rotated on its own axis by suitable mechanism for winding on yarn. The inner ends of the rods are preferably made conical, to accurately centre the spool or bobbin in the holder. A spring is made to act upon the loosely mounted rod or spindle to force it inwardly and into yielding contact with the spool. The device or holder is provided with a trip latch for retaining it in an elevated position, or in such position that the spool or bobbin when mounted in the holder will not be in contact with the winding mechanism, in order that the spools or bobbins may be more quickly and conveniently inserted into and removed from the holder.—No. 8681. May 24th, 1889. 8*d.*

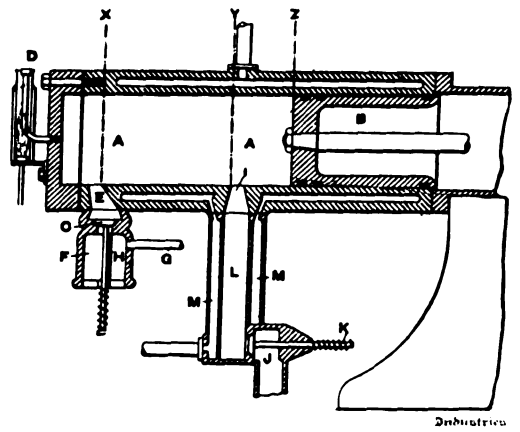
Engine for Terrestial and Aërial Propulsion.—*F. T. Millet, Persan par Beaumont, France.*—The engine is designed for driving vehicles such as private carriages, velocipedes, &c. The cylinders of this engine are mounted upon the driving wheel, so as to constitute the spokes or arms of the wheel. Their connecting rods and crank of their common axle are enclosed in a central lubricating box or hub. The illustrations show the parts of a gas engine constructed according to this invention for driving a



velocipede. Fig. 1 shows the complete engine, Fig. 4 a part vertical section through the driving axle and a cylinder, and the remaining figures show details. The five cylinders A are fixed to the hub B, which is traversed by the cranked axle E F G, one end of which is channelled for the admission of carburetted air. The pistons C of all the cylinders are connected, by rods D, to the same crank pin E. The crank discs G have a concentric ring of teeth in gear with an internal ring H, having double the number of teeth, by means of intermediate pinions I I, as shown in Fig. 6. The rings H have cams on their periphery for working the valves R S. L is a locking lever pivoted to the steering fork M and operated by a cam situated at the upper part thereof, for engaging with the crank arm K (fast on the crank axle) when the engine is required to work the cylinders revolving around

the stationary axle. As the admission pipe N for the carburetted air does not allow of placing the treadle cranks directly upon the wheel axle, they are geared by pitch chains enclosed within an oil-box with the pinion J. At the upper end of each cylinder a contact point is fixed in the porcelain insulator O, and is connected with the external contact fixed on the ebonite insulator T, bolted to the rim C¹ of the wheel. On the left-hand side is a treadle P, by which, and by the treadle Q, muscular power is applied at starting or to assist the engine when necessary. The carburetted air admitted by pipe N to hub B is drawn into the cylinders through the inlet valves R, which are operated at proper times, the gases of combustion being exhausted through the valves S. Upon the hub of the right-hand treadle Q is formed a double-grooved cam X to distribute the ignition electric current. For this purpose a small lever U (see Figs. 2 and 3) is operated by the cam, and through a multiplying lever V and traction rod D causes the pivoted brush carrier Y to distribute the current from the insulated brush Z to the contacts T, upon the rim of the wheel at every alternate revolution of the latter. The engine works as follows:—Motion is first obtained by the use of the treadles; the latch L is then lowered and engages with the crank, causing the pistons and parts to work as the cylinders revolve and so bring the engine into use. The cycle of operations in each cylinder is as follows:—Assuming the piston C (Fig. 4) to be at the top of the cylinder and the crank consequently upwards, the right-hand cam H will be at the point of lifting the admission valve R, and the piston C about to draw in the explosive mixture from the hub B through the channel of the axle F. After the wheel has made half a revolution, the valve R closes and the piston returns towards G¹ and compresses the explosive mixture. On reaching its highest point, the contact point, traversing the insulator O, comes in contact with the piston, and as it recedes from it in the second revolution the contact T is touched by the brush Z, which is brought into position by the cam X, and a spark is thus formed exploding the charge. When the cylinder arrives at its lowest position, the left-hand cam H lifts the valve S, and the exploded charge is expelled through small holes in the pipe leading to the valve. The cycle then recommences. The electric current may be produced by a dynamo driven by the machine, by a battery, or any convenient means. Fourteen claims are made.—No. 5199. March 26th, 1889. 1*s.* 1*d.*

Rotary Engines.—*H. Igel, Newcastle-on-Tyne.*—The engine has one or more cylinders fixed to the shaft so that their axes are at right angles to the axis of the shaft. The piston rod of each cylinder protrudes through both the cylinder's ends, and its piston is secured to the centre of the rod. The ends of the piston rod carry small rollers or bowls which work against the surface of a continuous cam, and cause the cylinders and the shaft to revolve. In the accompanying illustrations are shown an end and side elevation of a single cylinder engine. The cylinder C is mounted by the trunnions or shafts K upon the brackets L L¹ secured to the base plate. Its piston rod J carries the rollers

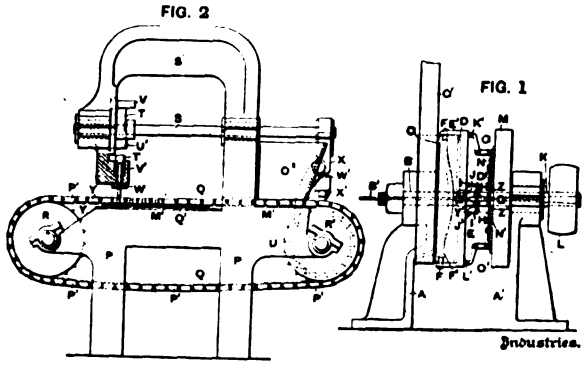


B, which follow the surface of the cam A as the piston makes its strokes. The cam A may have any odd number of projecting surfaces; the number must be odd, so that during the time one end of the piston rod descends the incline of one projection the other end ascends the incline of the other. By this means the cylinder is caused to revolve about the axis of its trunnions, or, on the other hand, if the cylinder be fixed and the cam free, the cam will revolve. The trunnions of the engine are hollow, and the motive fluid supplied through one and exhausted through the other. In the plate D are formed two ports communicating with the ends of the cylinder. This plate fits a circular valve, having as many ports as there are inclines in the cam; one alternate half of these ports communicate with the motive fluid, and the other with the exhaust, so that as the cylinder revolves with the plate D the ends of the cylinder are alternately supplied with motive fluid and exhausted. Claims: (1) In an engine a reciprocating cylinder or cylinders in combination with cams as shown and described, or any modification thereof for the purpose specified; (2) the arrangement for cutting off the motive fluid as shown and described, moved direct or indirect by any revolving part of the engine; (3) a reciprocating rotary engine constructed with all or any of the above combinations of parts.—No. 7937. May 13th, 1889. 8*d.*

Brake Gear for Railways, &c.—*J. Cleminson, London.*—This invention refers to a new method of constructing the brake rigging of railway and other vehicles. The brake block carriers have bosses upon their sides to receive the ends of a tubular strut, which joins the carriers and maintains them at a proper distance apart. A flat strut is placed on the tubular strut at its centre and at right angles to its length. One end of the strut is bored rather smaller than the tube and is heated to be placed in position on the tube. The other end forms the means of connection for the brake levers. To keep the carriers tight against the tubular strut and give rigidity to the whole a tie rod is passed obliquely through the carriers, and through a hole in the flat

Digitized by Google

strut, forming with the tube a triangular structure, and having the flat strut connecting the apex with the base (the tube). The tie rod is screwed at its ends, to enable the whole of the parts to be tightened up. Claim: The general combination and arrangement of parts together constituting the improved arrangement of brake beams as described.—No. 8215. May 17th, 1889. 6*d*.



Gas Engines.—*J. Roots, London.*—The engine has a working stroke each revolution, and its valves work automatically. In the illustration, A is the cylinder, B the piston, and D the red-hot tube igniter of the improved engine. To start the engine a small charge is first drawn in and then compressed into the red-hot tube D; the explosion thus occurs, and the piston B makes its working outstroke. When the piston uncovers the exhaust port I the excess of products pass out by the pressure opening the valve J. The piston continues its outstroke and the valve J closes, whilst the exploded charge in the tube T becomes cooled, and in contracting causes more explosive mixture to be drawn in through the valve C. The piston now commences its instroke, forcing more of the products out, until it covers the port I, when

compression of the explosive mixture commences, and at the end of the instroke at the highest point of compression ignition occurs, and the cycle of operations recommences. Claims: (1) The completing of the cycle of suction, compression, explosion, exhaust, in one revolution—*i.e.*, one outstroke and one instroke in the manner described with reference to the illustration; (2) the cooling or condensing chamber L as arranged and combined with the open end cylinder A having two ports only, as set forth; (3) the construction, combined with a condensing chamber as hereinbefore described, whereby the four operations occur on the same side of a piston in a cylinder and in one revolution; (4) placing the automatic exhaust valve at a distance from the exhaust port as and for the purpose described; (5) the partition H in a gas engine admission chamber for preventing the admixture of gas and air before entering the cylinder.—No. 3972. March 6th, 1889. 6*d*.

Boot Machinery.—*W. Ross, London.*—This improved machinery is for the purpose of manufacturing studs, and subsequently inserting them in the soles of boots and shoes. It consists of improved automatic devices for the intermittent feed of the length of wire from which the studs are cut, the cutting up of the wire into studs of even length, their regulated feed to the inserting mechanism, and subsequent insertion in the sole leather. Fig. 1 is an elevation, partly in section, of the devices for feeding up the wire, and cutting it up into studs. Fig. 2 is an elevation of the mechanism for receiving and feeding the studs, and inserting them into the sole leathers. The figures illustrate the invention as consisting of two isolated machines. These may be arranged either side by side, or with the stud-cutting mechanism over the inserting mechanism, as may be convenient.

FIG. 2

Referring to the stud-making machine, B is a hollow mandrel, supporting the driving pulley C and a disc E with flanges E¹. The flanges E¹ are made to slide upon part of C, and carry studs F, which travel in grooves F¹ cut in the pulley C. The mandrel B is stationary, and the disc E connected to it by a feather D¹. In the mandrel B are arranged two milled rollers G¹ G¹, which are rotated by ratchet wheels and pawls. The ratchet wheels and pawls are actuated by a to and fro movement of the disc F, due to the travel of the pins in the groove F¹. The milled rollers grip the wire B¹, and feed it to the knives N N¹. The knives are fitted to a disc M upon the mandrel K, and rotated by the pulley L. Bell crank levers O O¹ slide the knives together as the disc E is moved to the right. The knives are thus operated by the movement of the disc to the right, whilst the wire is fed forward by its movement to the left. Two backward and forward movements of the disc E occurs each revolution of the pulley C. In Fig. 2, M¹ is the table on which the sole Q¹ is placed to be studded. Q is the stud feeder, made in the form of an endless chain. Each link has one small hole to receive one stud, which it takes up as it passes under the hopper O². The driver T is forced down by a hammer U¹, which is raised by the cam T¹ working against the projection V. A ratchet wheel U and pawl drives the carrier Q intermittently. Three claims are made.—No. 3965. March 6th, 1889. 8*d*.

Railway Couplings and Buffers.—*R. M. Mark, Birmingham.*—In this specification is described a combined coupling and buffer. It consists of a hollow projecting block having externally the general form of a buffer. In longitudinal slots in the side of this block are pivoted two strong levers with their fore ends hooked. The rear ends are connected by links to a sliding rod which is pressed forwards by a coiled spring, and so keeps the hooked ends or jaws closed. The opposite block consists of a hollow cylinder sliding upon a second hollow cylinder secured to the carriage. Passing through the centre of both cylinders is a sliding bolt surrounded by a coil spring which tends to push the outer and buffer-shaped cylinder forwards. To the outer or buffer-shaped cylinder is secured a wedge-shape hook which engages with the hooks upon the other block when the two are forced together. To release the hooks one from the other a rack is attached to the sliding rod in the first block, and is operated by hand wheels at the side of the vehicles. By this arrangement the sliding rod is pulled backwards and the jaws opened to release the hook upon the second buffer. Claims: (1) An automatic coupling consisting essentially of two horizontal hook-ended lever jaws on the one end of one vehicle and a sliding spring rod having a double wedge or heart-shaped head on the end of the adjacent carriage or vehicle, the said hook-ended lower jaws being pressed together or closed by a spring and engaged with the double wedge-shaped head for coupling the carriages or vehicles, the said lever jaws and double wedge-shaped head and parts connected with them being constructed, arranged, and working as described; (2) the arrangement and combination of parts described in connection with the hooked and lever jaws for uncoupling the vehicles by hand; (3) the construction and arrangement of the parts of a buffer as described.—No. 8722. May 27th, 1889. 8*d*.

Spinning Machinery.—*T. Watson, Belfast.*—Improvements are here introduced in the quadrants of spinning and twisting frames, whereby an instantaneous reversal of the upward and downward motions of the "builders" is obtained. In the accompanying illustration the figures are respectively front and side elevation and plan of a portion of a spinning frame sufficient to describe the invention. Q is the quadrant capable of turning freely on the stud D or fixed centre of motion at the side of the frame. This quadrant receives an intermittent vibratory motion from the quadrant pinion A¹ which rotates always in the same direction and which has given to it at certain parts of the motion a vertical motion of translation. Free to rotate on the same stud A as that to which the pinion A¹ is keyed, but not to move longi-

FIG. 1

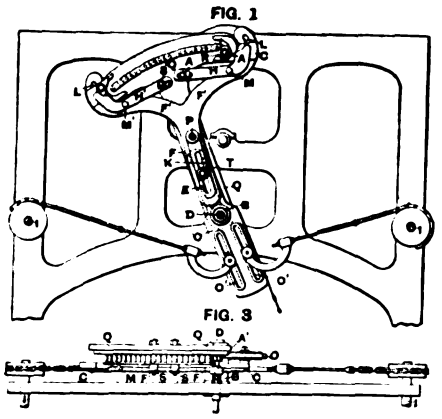


FIG. 2

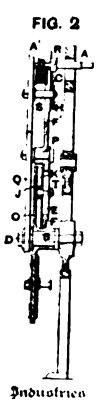

FIG. 3

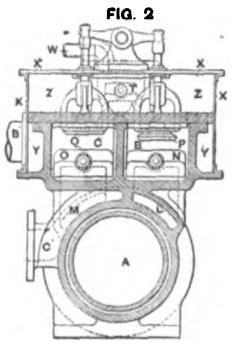
tudinally, is a roller R. J is a lever having one end double and the other straight, the lever being capable of turning freely on a pin P fixed to the quadrant Q, and therefore moving with it. The arms F¹ of the bifurcated end of the lever J have a cam plate C attached to each of them, and they can each be adjusted in the slot L to suit the different motions desired to be imparted to them by the roller R. The lower arm of the lever J has an adjustable stud T, which carries a collar J free to travel in the slot K of a lever O. The lower end of lever O has connected to it the chains of the "builder" shafts I. By this arrangement of parts the roller R, at the time the pinion A¹ shifts from its upper to its lower position or *vice versâ*, comes into contact with one of the cams C, and, by depressing it, causes the lever O to continue travelling in the same direction until the pinion A¹ has changed its position and the motion is reversed. To hold the lever J in the position they are placed at the end of each motion, the locking levers H H¹ are provided. The levers H H¹ are unlocked at the end of each stroke by the roller R. Six claims are made.—No. 20167. December 14th, 1889. 8*d*.

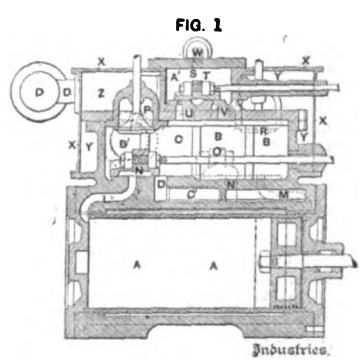
Tuyeres.—*S. Heartland, London.*—The tuyeres are made with removable nozzles, which fit the body of the tuyeres by means of a male and female joint, so as to render the connection steam-tight. The nozzle is made of chilled cast iron, and it is either bolted, cramped, or cottered to the body of the tuyere. Two claims are made for the method of jointing the parts and connecting them together by bolts, &c.—No. 4943. March 21st, 1889. 6*d*.

Laminated Springs.—*Steel, Peech, & Tozer, Ld., & S. Oakes, Sheffield.*—A machine is here described for fitting the plates of laminated springs. Upon one end of a horizontal metal plate are arranged rollers for "pinching in" the spring plates. In the surface of the plate are holes for the reception of dogs fitted with screws and shoes by which they can be adjusted to suit the different lengths of springs. Between these dogs is arranged an arm which has a reciprocal motion in the plane of the plate's surface. The machinery for driving the rolls and the arm is situated below the surface of the plate. The springs are formed in the following manner: A suitably curved back plate, technically called a "crib," is first formed of the desired curve. A heated spring plate is then placed behind the "crib," and the two passed together through the rolls, accomplishing the "pinching in" operation. The two plates are then placed upon the block, with their ends against the shoes of the dogs, and the arm caused to revolve. A sliding block upon this arm is now pressed against the heated plate and gives it the necessary camber of the hardened back plate or "crib." The hot plate is thus suitably curved and when hardened forms the "crib" for the next plate. Two claims are made.—No. 15914. October 10th, 1889. 8*d*.

Steam and Hot Air Engines.—*E. Field, London.*—The class of engines referred to is that in which steam with air, or products of combustion, are used as the motive fluid, and where the mixture of the gases is effected in the slide valve chamber. Fig. 1 shows a longitudinal section upon the slide valve chamber and cylinder of this improved engine, Fig. 2 a transverse section of the same, and Fig. 3 the arrangement of an engine with the flue of a boiler. A is the cylinder; it is externally heated or steam jacketed. B is a mixing chamber, communicating with the back end of cylinder and with the exhaust. C is the mixing chamber for the front end of the cylinder; D is the exhaust port from B, and J the exhaust port from C; N is the slide

FIG. 2





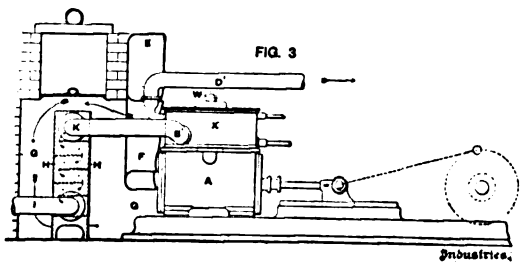


FIG. 1

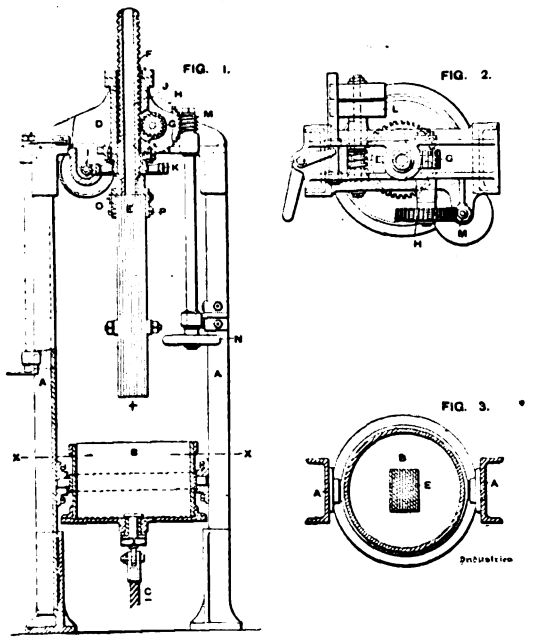
valve controlling the admission and emission of the mixture to and from the back end of the cylinder; O is a second slide valve for the front end of cylinder. The valves N and O are reciprocated by the same eccentric. P and Q are valves that serve for the exit of mixture alternately from the mixing chambers, and two similar valves (one, R, being shown) serve to admit alternately hot gases to the chambers. These four valves are opened and closed by rocking shafts. T is the steam slide valve, and W the steam inlet. An exterior casing X forms a chamber Y for the reception of the gases previously to their entering the chambers B and C. The operation of the engine is as follows:—The parts being as illustrated, the valve T is disconnected and worked by hand. In starting the steam valve is moved first to the left, opening the port Y and admitting steam to the chamber C. This steam will pass directly through C to the cylinder and drive the piston inwards. The steam valve is then moved to the right and the port U opened. Steam is thus admitted to the chamber B, but passes on through to the back of cylinder, causing the piston to make its outstroke. Speed having been got up in this manner by the use of steam alone, the mixture of the steam with air is then commenced. Assuming the parts to be again as illustrated, the valves N and O are moved to the right, and the back end of the cylinder thus opened to the exhaust. At this moment the valve P is opened for the exit of the mixture remaining in B from the previous charge, and shortly after a charge of hot air is admitted to B by the valve corresponding to R of the other chamber. Whilst these valves are being opened and closed the piston makes its inward stroke. After a charge of air has been taken into the chamber B the port U is momentarily opened and a charge of steam admitted, completing the mixture and giving rise to the desired pressure of the gases. At the end of the inward stroke the port L is opened to the chamber B, and the charge makes the outstroke of the piston whilst a similar preparation of a charge for the instroke occurs in the chamber C. In Fig. 3, E is part of a Cornish boiler whereof F is the fire tube

FIG. 3

and G is the flue. H is a heater located in the flue G, where it is surrounded by hot products of combustion. This heater is composed of a chamber with shelves so disposed that the gases shall be compelled to take a zig-zag upward course in order to ensure their being heated by contact with the heated metal; or a large coil of thin metal might be substituted or any other suitable arrangement be used adapted to impart heat and at the same time to prevent the mixture of the products of combustion with the gases to be heated. With such an arrangement as referred to, air or gases is or are forced by a blower or other suitable means through the pipe I into the heater H, and being heated therein, then passes or pass through the pipe K into the engine at B¹ for use as before explained.—No. 1997. February 4th, 1889. 11*d*.

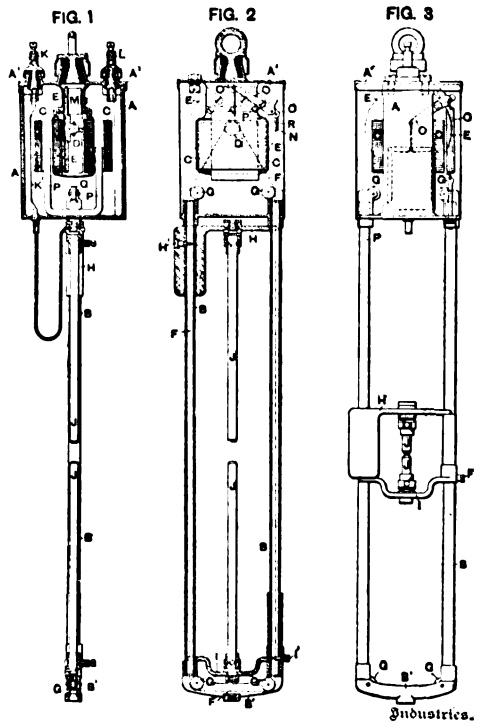
Sight Feed Lubricators.—*R. J. Threlfall, Gateshead.*—The following advantages are claimed for this lubricator:—(1) Automatic stoppage of the supply when the engine stops; (2) continued supply after steam is shut off, advantageous in locomotives; (3) shuts off the supply when sight feed glass breaks. The lubricator consists of an oil cylinder fitted with a packed piston whose rod projects out of the top end of the cylinder. The piston rod is made hollow to form an air chamber. The cylinder is in communication with a sight feed glass, and the supply of oil is controlled by a cone, plug, or cock, and by a ball valve which rolls upon its seat when the engine is in motion, but when the engine is stationary covers its seat and stops the flow of oil. When filling the cylinder with oil the piston is first pushed down to the



Digitized by Google

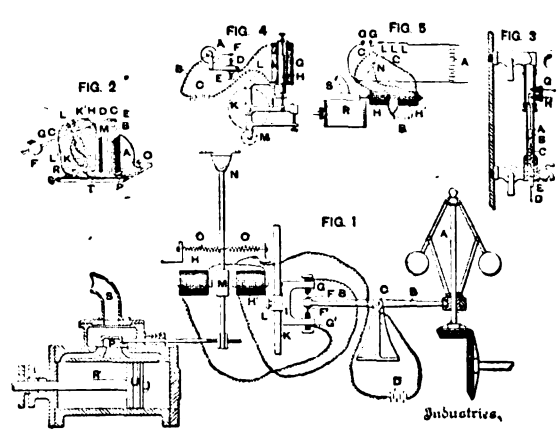
bottom and the oil poured in at the top. Steam is then admitted to the under part of the piston, forcing it up and exerting a pressure upon the lubricant equivalent to that in the slide valve or cylinder to be lubricated. The air chamber formed by the hollow piston rod is in communication with the top of the cylinder, so that the air is compressed by the oil, and in the case of steam being shut off, the compressed air continues to exert a pressure upon the oil and force it to the parts to be lubricated. Six claims are made.—No. 8847. May 28th, 1889. 8*d.*

BRIQUETTE MACHINERY.—*N. Procter, Leeds; A. Middleton, Ben Rhydding; C. E. Fraser, Leeds; H. M. Carter, Leeds.*—These improvements refer to the part of a briquette machine for feeding in the material. The feeding arrangement and the hot parts of the machine are separated by an intermediate connecting piece of wood or other non-conductor, which prevents the transmission of heat. A plate is also made to pass under the feeder to receive the material prior to its dropping into the machine, and whilst in that position prevents the passage of heat and steam into the feeder. The plate is given an automatic intermittent reciprocating movement, by any convenient means, for the purpose of withdrawing the plate and letting the material fall into the machine. Claims: (1) The employment of the intermediate connecting piece of wood, or other non-conducting material, for preventing the heat passing to the feeding arrangement; (2) the arrangement, construction, and application of a plate operated as described.—No. 11,403. July 16th, 1889. 6*d.*



ELECTRICITY.

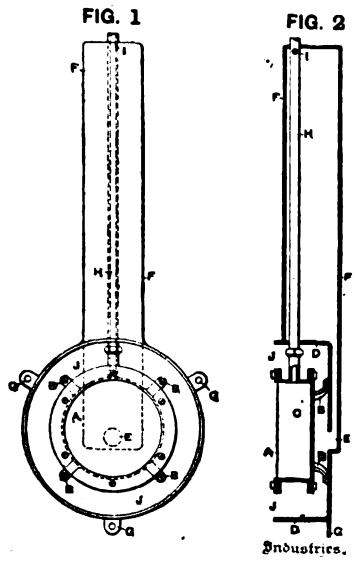
ELECTROLYSIS.—*M. Killiani, Neuhausen, Switzerland.*—In the electrolysis of a body in a state of fusion, when the heating of the electrolyte is effected by the current alone, the heated region is limited to the portion between the electrodes, unless the current be so intense that the mass between the poles is heated far above its melting point, and gives off heat to the surrounding particles. Such superheating, however, affects injuriously the separation of the elements, since the latter are all the more easily re-combined in the fused electrolyte, in proportion as the temperature is increased. Therefore, in order to secure economy of working, the temperature of the electrolyte must be kept as low as possible. If the current is maintained at a strength favourable for the electrolysis there forms at the surface of the bath a solid crust, preventing the addition of fresh material. To prevent the formation of this crust is the object of this invention. This the inventor does by giving the electrode a rotary motion about its axis. In the illustrations given, Fig. 1 is a vertical section of an elevation, Fig. 2 a plan, and Fig. 3 a horizontal section on the line X X of the machine. The pillars A A carry the receptacle B for the fused substance to be electrolised; the negative current is led into the substance from below by means of the conductor C. The bridge D on the two pillars carries the appliance for holding and moving the positive electrode E. In the head J there is the spindle F of the electrode, its vertical section showing the form of a rack into which the pinion G gears, the latter being worked by the hand wheel N by means of the worm gearing H M. The anode shown at E is inserted into the head O and held therein removably by means of the clamping or binding screws P. The head O is screwed upon or otherwise fastened to the lower end of the cylindrical spindle rack F, which works loosely in the centre of the bridge or crosshead. On the spindle F there is



mounted a wormwheel K secured by a feather key in such a manner that the spindle can be moved endwise through the eye of the wheel K. The worm I gears into the worm wheel K and is connected to the shaft of the driving pulley L. By revolving the belt pulley L motion is imparted to the electrode E, and by reason of its angular form stirs the bath and prevents the formation of a crust. Vertical adjustment of the electrode is made by the hand wheel N. Claims: (1) In the electrolysis of bodies capable of fusion the hereinbefore described method of protecting the surface of the electrolyte from solidifying, and of uniformly distributing the solid additions among the molten contents of the bath, the said method consisting in imparting motion to one or both electrodes in a pendulous or circular or eccentrically rotary manner; (2) in an apparatus for the electrolysis of bodies capable of fusion an electrode (or electrodes) moving with a pendulous or circular or eccentrically rotary movement with relation to the bath, and capable of being adjusted in a vertical direction.—No. 6745. April 20th, 1889 8*d.*

ARC LAMPS.—*S. Z. de Ferranti, London.*—The carbons are brought together in this lamp by the action of weight, but are prevented from approaching too near by a clutch arrangement. The action of the clutch is controlled by the movable core of a solenoid, and a magnetic brake controls the speed at which the carbons approach one another. In the accompanying illustrations of the lamp, Fig. 1 is a vertical section, Fig. 2 a side elevation partly in section, and Fig. 3 a side elevation of the lamp with the solenoid core in its lowest position. The mechanism is enclosed in a cylindrical casing A, having the guide rods B attached to its bottom part. The cover of the casing A supports the solenoid coils C and the toothed wheel D, which is secured to the thin iron disc E. The cover also carries an iron plate having a number of parallel projections M, which are in close proximity to the disc E, and constitute the pole pieces of a multiple-pole electromagnet. An endless chain F is geared to the wheel D and passes through the tubular guides B and over the pulleys G. The chain is secured by the pins H^1 I^1 to the top and bottom guides H I. The slide H is insulated from the guides and electrically connected to the terminal K. A conductor from the other terminal L is wound in and out the pole pieces M, then coupled to the coils C, and from these connected to the rods B, upon which the guide I slides. The disc E has ratchet teeth around its periphery which engage with a pawl N carried by the lever O. The lever O is acted upon at one end by the solenoid cores P, and at the other by a coiled spring O^1. The action of the mechanism is as follows: By the extra weight of the top guide there is a tendency of the carbons to approach each other, but by reason of the pawl N they remain stationary. When too little current passes, however, the solenoid core drops and the pawl N is carried upwards; its inclined lower end then comes against a fixed pin R, and the pawl is thereby disengaged from the teeth on

the disc; the carbons then begin to move together. When by the bringing together of the carbons more current is allowed to pass, and the core is consequently drawn upwards into the solenoid, the pawl is carried downwards away from the pin R and again engages with the ratchet teeth on the disc, and if too much current is passing it turns the disc in a direction to separate the carbons. So long as the pawl is engaged the distance between the carbons is controlled by the position of the solenoid core. As the iron pole pieces of the electromagnet M are magnetised alternately north and south, and their extremities are in close contiguity with one side of the iron disc E, a series of closed magnetic circuits are created, which securely hold the disc from rotating so long as current passes, but momentarily release it at each alternation in the current. Five claims are made for the lamp described and a modification.—No. 7275. May 1st, 1889. 8*d.*



REGULATING APPARATUS.—*W. J. L. Hamilton, Portrush, Antrim.*—The apparatus consists of a delicate and sensitive device which sets in action a small force which in its turn brings into play a greater force for effecting the operation. Fig. 1 shows an apparatus adapted for regulating the speed of a motor. The governor A, in rising and falling, shifts the lever B and makes contact with G or G^1. A current is thus passed in one or the other direction through the magnets H H^1, and moves the pendulum M to the right or left as the case may be. The rod of the valve P is secured to M, so that the former is moved by the motion of the latter and working fluid is admitted to one end of the cylinder R. The piston U is made to control a regulating valve upon the motor, so that the admission of fluid to the cylinder either opens or closes the motor regulating valve. Fig. 2 illustrates a method of keeping a constant potential in electric installation, using a voltmeter as the indicator. In this a solenoid A, which is in connection with the positive and negative mains, controls a contact device similar to that already described. The solenoids H H^1 (Fig. 1) are electrically connected to this device, so that by the motion of the lever C the valve P is operated, and the supply of working fluid regulated to the engine driving the electric generator. In Fig. 3 is shown the appliance adapted to a water gauge to indicate the water level. A float B makes contact with the electric terminals G H. Fig. 4 shows the appliance adapted to a shaft bearing to prevent it becoming overheated. The bearing is water jacketed, and has attached to it a thermometer A. By a rise of temperature in the bearing, and consequently the thermometer, contact is made between F D, and the solenoid G is vitalised. The core H, with the lever I, are thus raised, and partially revolve the wheel K. The wheels K, M, L are in gear, and the two latter connected to cocks controlling the flow of oil and water to the bearing. By the partial revolving of the wheel K the wheels M and L revolve and open their respective cocks. In Fig. 5 the appliance is again shown, combined with selenium cells to automatically extinguish street electric lights when the moon shines. The current from accumulators A passes through selenium cells L and through the coils of a galvanometer by its terminals G G. Its needle N is thereby deflected, and as it strikes

one or other of the terminal contacts C C and closes a circuit, it sends a current from the battery B through one or other of the solenoid coils H H^1, which act on the slide valve of the hydraulic cylinder R. The piston rod works a switch in the main lamp circuit whereby the lamps are lighted or switched off. Eight claims are made.—No. 6027. April 8th, 1889. 8*d.*

MISCELLANEOUS.

WATER TELEPHONES.—*W. Walker, London.*—In apparatus employed for the collection of sound transmitted through water, such as between ships, some difficulty is experienced in properly recording the sounds on account of the instrument being worked by other causes such as the movement of the ship. The inventor remedies this defect by constructing the apparatus so that any pressure caused by the increased density of the water has no effect upon such apparatus. Referring to the illustration, the telephonic receiver C is secured concentrically within the cup D. By a passage E the cup D communicates with a closed tube F. Passing through the tube F is a second tube H having at its upper end an orifice I. One end of the tube H leads to the chamber C, and the other to a pressure gauge on the ship. A is the diaphragm of the receiver. The action of the apparatus is as follows: Assuming the same to be applied to a ship, any alteration that takes place in the position or motion thereof will cause a difference in the external pressure acting upon the diaphragm A, which is counterbalanced internally by the pressure of air in the chamber C and tube H caused by the water rising in the

chamber F in proportion to the depth to which the instrument is immersed. This compensation takes place each time the apparatus is raised or lowered by the motion of the ship in the water, and ensures only the sound waves affecting the diaphragm. The area of the space J through which the water enters to the chamber F being equal to the area of the diaphragm A, an equal pressure acts upon each when the instrument is so placed as to receive the full force of the water through which it is passing, or which is passing it; by this arrangement the equilibrium of the diaphragm is maintained. Three claims are made for the apparatus described and a modification.—No. 5187. March 26th, 1889. 8d.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED ORE CRUSHING MACHINE.

We herewith illustrate a form of ore crushing machine now being made at the Fulton Ironworks, San Francisco. The principal strains fall on double links of wrought iron, as shown in Fig. 1. The cast iron parts are reduced to a symmetrical form, and the crushing faces are built up in sections, or composed alternately of bars of hardened steel and soft iron. This construction produces a self-maintained corrugated face, by reason of the soft metal wearing away faster than the hard steel. The front abutting plate is hinged, and can be thrown down, as shown in Fig. 2, thus permitting free and ready access to the dies. When this plate is closed up, the die is clamped against the ledges on the main frame and requires no other fastening. The machines are driven at 225 to 250 revolutions per minute, and will crush one ton per hour for every two inches of width on the faces—that is, a machine 16in. wide will crush 8 tons per hour when the limit of the throat is 1½in.

THE S.S. "PRINS WILLEM II."

We illustrate on pages 412, 413, and 420 the general arrangement of the engines and boilers of the steamer "Prins Willem II.," built at the "Koninklijke Fabriek van Stoom e. a. Werktuigen," Amsterdam, for the Royal West Indian Mail Service. This steamer is one of the best which has ever been designed and constructed in Holland, and the following description, together with the illustrations, will be of interest, as affording an indication of modern Dutch engineering practice. We intend in a succeeding issue to illustrate the engines of the vessel in greater detail.

The ship is 275ft. long, 36ft. broad, and 21ft. deep, and her displacement at 18ft. draught is 3,000 tons. On the trial trip the engines developed 1,235 i.h.p. at 72 revolutions and gave 13 knots an hour. The engines are of the triple-expansion surface-condensing type, the cylinders being 22in., 24in., and 56in. in diameter, and the stroke 40in. The low-pressure cylinder is placed between the other two. The pistons are fitted with Buckley's piston rings. The slide valves of the high-pressure and of the intermediate cylinders are cylindrical and fitted with springs. The low-pressure valve is a flat, double-ported slide valve. The valve gearing is of the radial type, designed by the late Mr. Robert Wylle. The reversing gear is worked by steam. The weight of the slide valve of the low-pressure cylinder is balanced by steam pressure; the top end of the valve rod being provided with a piston, which slides in a cylinder fitted on the top of the valve. The crank shaft is made of steel 11¼in. in diameter, and has three cranks; there are two bearings, one between each crank. The piston rods and valve rods are made of steel, and the connecting rods of wrought iron. The cylinders are not jacketed.

There is one single-acting air pump, worked by levers from the cross-head pin of the piston rod of the intermediate cylinder. The diameter of the pump is 20in., and the stroke 20in. Kinghorn's valves are used. A manhole is made in the side of the vertical pump barrel so as to command a view of the valves. A double-acting circulating pump is worked in the same way as the air pump, from the cross-head of the high-pressure cylinder. It is fitted with two vertical suction valves and two vertical pressure valves of india-rubber. The diameter of the barrel is 14in., and the stroke is 20in. Two feed pumps and two bilge pumps, with a stroke of 20in., and a plunger with a diameter of 3½in., are worked by the cross-beams of the air and circulating pumps. The condenser is cast to the framing, and is fitted with 801 brass tubes ¾in. outside diameter. The tubes are fixed to the tube plates by wooden rings. The cooling surface is equal to 2,000 square feet.

The bed-plate is made of cast iron, and is cast in one piece with the lower half of the condenser. The foundation in the ship is built up of plates and angle iron on the top of the frames.

There are two single-ended boilers, 10ft. 7¾in. diameter and 13ft. 6in. long. Each boiler has three Purves' ribbed furnaces, 37in. in diameter. The boilers are of steel, and are made of plates 1¼in. thick. The tube plate is ¾in. thick, and the sides of the combustion chamber $\frac{9}{16}$in., both of iron. Each boiler has 300 tubes, including stay tubes. The length of each grate is 6ft., and the length between the tube plates 7ft. The tubes are 3¼in. outside diameter, and are made of iron. The heating surface of each boiler is 1,900 square feet, and the grate surface is 55½ square feet. The working pressure is 160lb. per square inch.

The propeller is made entirely of steel, and of the Griffiths type, with a double pitch in the blades. There are four movable blades. The propeller diameter is 14ft. 8in., and the pitch 17ft. 3in. and 18ft. 3in.

IMPROVED ORE CRUSHING MACHINE.

CONSTRUCTED BY THE FULTON IRONWORKS COMPANY, SAN FRANCISCO.

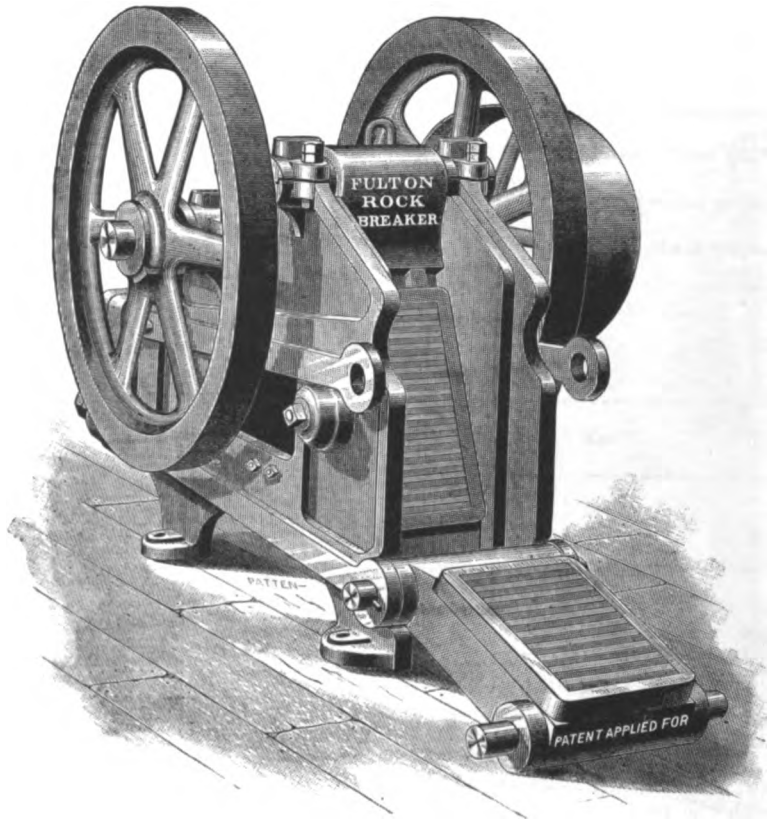

FIG. 1.

NOTES ON ALLOYS.

IV.

SOME additional valuable information on the aluminium alloys is given in a paper by Messrs. Hunt, Langley, and Hall, on "The Properties of Aluminium, with Some Information Relating to the Metal," read at the meeting of the American Institute of Mining Engineers in February last. The authors give the following numbers for 10 per cent. aluminium bronze rolled into plates, viz.:—Elastic limit, 75,000lb. per square inch; tensile strength, 110,000lb. per square inch; reduction of area, from 20 to 40 per cent., and an elongation of 5 to 10 per cent. in 8in. Its specific gravity in castings is about 7·84, and in rolled sheets about 7·89; its modulus of elasticity, 18,000,000lb. In castings, the tensile strength is 70,000lb. to 80,000lb. per square inch, with a reduction of area of about 20 per cent. Compression tests upon bars of ·75in. diameter and 2in. long gave an ultimate compressive strength of 160,000lb. per square inch and a shortening of ·25in. It melts at about 1,700° Fahr., and has a slightly less shrinkage than ordinary brass; it solidifies very rapidly from its molten condition, and hot-baked sand moulds should be used for casting, and the surface of the molten bath should be kept covered with powdered charcoal or with flux, if a slight addition of silicon to the alloy does not matter, in order to prevent oxidation. The metal should also be tapped in an inert atmosphere (smoke) for the same purpose. The authors further point out that the alloy does not corrode in air or water, is very dense, can be worked at a bright red heat as easily as can wrought iron, while all other bronzes are red short at a red heat. As it is malleable at a red heat, and is permanent at this temperature, it is admirably adapted for blast furnace tuyeres. For soldering, zinc and venetian turpentine is recommended, and for brazing, an alloy of equal parts of zinc and copper mixed with three times its weight of flux consisting of equal weights of borax and cryolite.

The analyses of alloys made by the Pittsburgh Reduction Company and the Scovill Manufacturing Company are given in Table I. on the next page. In the table, the column Si (*a*) gives the percentage of graphitoidal silicon, and Si (*b*) that of the non-graphitoidal silicon present. The authors in their paper then refer to the alloys of aluminium and iron, and point out that the addition of aluminium not only makes wrought iron fluid, as in Mitis castings, but at the same time increases the tensile strength and improves the fibre of the

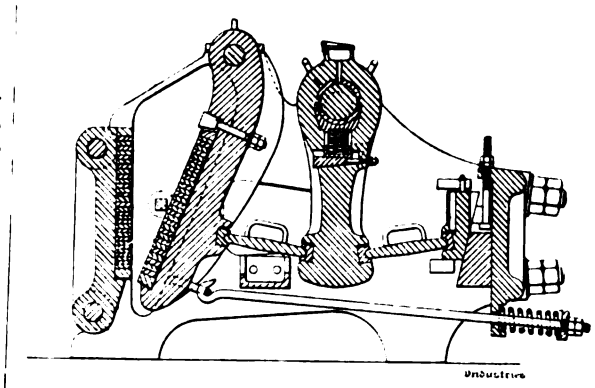

FIG. 2.

metal. With cast iron, as W. J. Keep has shown, the addition of aluminium converts the combined carbon into graphite and closes the texture of the metal. The aluminium can be added as pure metal or in the form of ferro-aluminium in quantities from 0·1 to 2·0 per cent. Aluminium added to steel also turns the combined carbon into graphite, and thus tends to soften the metal. Less than 1 per cent. of aluminium added to a steel rich in carbon increases the tensile strength without decreasing the ductility. It also lowers the melting point and thus increases the fluidity.

Table II., on the next page, summarises the authors' work on the influence of aluminium on various grades of iron and steel.

M. F. Osmond has also recently studied the influence of other foreign elements on the properties of iron and steel, by his thermometrical method, which was first described in the *Comptes-Rendus* for April, 1887. The author then found that when electrolytic iron containing only 0·08 per cent. of carbon was allowed to cool down slowly from the molten state the heat was liberated at different temperatures: the first disengagement called a_3 takes place at 855° C., and in cooling when this temperature is reached the thermometer remains stationary for a very prolonged period; the second disengagement of heat a_2 takes place at 730° C., but it does not appear to be so marked as the first. The transformation of the iron from the allotropic condition known as β to that of α takes place when this first liberation of heat at constant temperature takes place, and the lower temperature corresponds either to

the end of this change, retarded by the presence of carbon in different parts of the mass, or to another allotropic modification of the metal taking place.

The carbon itself, in passing from the combined to the graphitoidal condition, gives rise to another period of constant temperature called a_1, and which Barrett calls recalescence. Although these points are sufficiently characteristic for any given metal, the temperature halts which they denote vary with the foreign elements present, and M. Osmond has in this present communication investigated the influence of the elements boron, nickel, copper, silicon, arsenic, and tungsten upon the temperature values of a_3, a_2, and a_1.

The alloy containing boron was obtained from Professor Roberts-Austen, and when examined by this method the value for a_3 was found to be lowered to 810°, while that of a_2 remained between 735°–725°. Boron, therefore, acts upon the metal in much the same way as does carbon.

For determining the influence of nickel a nickel steel was made in the laboratory of M. Troost, containing 0·34 per cent. of carbon, 5·97 of nickel and traces of manganese. For a steel without nickel, but containing this amount of carbon, a_3 and a_2 would be practically identical, but completely distinct from a_1. The addition of nickel caused a further lowering of the temperatures of a_3 and a_2 until they coincided with that of a_1, there being only one critical point (660°–640°) for this alloy. This temperature is lower than the normal temperature of recalescence. Dr. Hopkinson has also found by a different method that a large percentage of nickel causes a lowering of the point of recalescence. Nickel in this respect resembles manganese. The action of copper on changing the temperature values of the points a_3 and a_2 was also found to be analagous to carbon, but less energetic, 4 per cent. of copper having about the same effect as 0·25–0·3 per cent. of carbon, while its effect on the point of recalescence is similar to that of nickel and manganese.

The alloys experimented with were prepared by Messrs. Ball & Wingham, of South Kensington. They had the following composition:—

	1	2	3
Copper.....	0·847	4·10	4·44
Carbon.....	0·102	0·183	less than 0·10

The values for a_3 and a_1 were lowered, and in the two specimens with most copper a_3 and a_2 coincide at a temperature 730°–720°, while a_1 is as low as 625°–600°.

For silicon, some steels prepared by Mr. Hadfield contain 0·20–4·40 per cent. of this element and only very small quantities of all other foreign elements. The experiments show that the addition of silicon causes a diminution of the amount of heat disengaged in a_3, and when the amount added is about 2 per cent. this critical point disappears entirely. This disappearance, however, differs from that which takes place with carbon, manganese, nickel, or copper, since the heat does not appear at any lower temperature. In fact, no evidence of any allotropic change in the iron corresponding to the change from β to α is found between 1,400°–500°. In other words, it seems that the addition of silicon to the iron does not induce any change from the α to the β condition, and that, therefore, in subsequent cooling there is no change possible. At the same time, as this critical point disappears, a_2 gradually is lowered from 730°–720° to 710°–700°, while a_1, or the recalescence point, is raised from 660°–650° to 710°–700°, so that the two points a_2 and a_1 coincide.

Arsenic also acts as silicon, a_3 losing its intensity and being raised in position with quantities up to 0·55 per cent. There is no apparent influence on the values for a_2 and a_1.

Tungsten in quantities up to 1·5 per cent. has no influence on the value for a_2, but lowers a_1 considerably, reaching a temperature 510°–530° with the castings which are richest in tungsten.

This method of research undoubtedly gives very interesting theoretical results, but at present we are hardly in a position to show the relationship which obviously must exist between these changes and the amount of chemical and physical union of the various elements in the alloy. The author has done well in selecting alloys whose chemical composition is definitely established, and which have had their physical constants determined, and we shall look forward to the time when the connection between these figures will be generalised into a useful working law.

Two new alloys of mixed composition have recently been described which are likely in the near future to receive important useful applications. The first of these has been patented by Herr Rieth, of Bockenheim, and consists of copper 15 parts, tin 2·34, lead 1·82, and antimony 1 part, and may be looked upon as a bronze to which small quantities of lead and antimony have been added. The inventor states that this alloy practically resists the attacks of most alkaline and acid solutions, and he believes that it can be used with great advantage in the laboratory to replace vessels or fittings of ebonite, vulcanite, or porcelain. The second of these new alloys is called *schmiedbarenguss*, and is a patented mixture of pig and wrought iron to which aluminium bronze and ordinary bronze has been added, with the addition of a flux. The most important characteristic of this material is that it can be manufactured direct in the cupola without annealing, and that therefore its cost of production need not be high. It is stated to produce weldable, malleable, soft steel castings of great ductility and strength, and to have a specific gravity of 7·16. The United States Government has given the following data with regard to its physical properties:—A test bar, ·225in. × ·512in., subjected to a tensile stress of 26,200lb., equal to 200,766lb. per square inch, did not break. With a length of 12in. between the supports, a transverse load of 7,232lb. was necessary to rupture the bar. Twenty-nine test bars that were broken showed a reduction of area of 28–67 per cent.; elongation, 52·1 per cent.; resilience, 37–45 per cent.; compressive strength per square inch, 200,853lb.

We defer our notice of Messrs. Wright and Thompson's paper on ternary alloys for the present.

ALUMINIUM AND ITS USES.

At the present time we are constantly seeing paragraphs in the daily press, and also in *soi-disant* technical journals, describing new processes for extracting aluminium from its ores, and also giving absurdly exaggerated accounts of the usefulness of this metal and its alloys in the industrial and artistic world. There are two ways in which damage can be done to a valuable discovery—viz., by abuse and by over-praise. That aluminium may not eventually have to be saved from its friends is by no means uncertain, and this baleful influence can only with certainty be removed by its advocates strictly honouring the limits of truth.

It may be remembered that Mr. J. H. J. Dagger, F.C.S., F.I.C., read a paper on "Aluminium" before the last meeting of the British Association. This paper was so valuable, and so much interest was aroused by it, that the Cowles Syndicate asked Mr. Dagger to prepare a supplementary account of the properties and functions of this metal. We received a copy of this pamphlet a few days ago, and we consider the information contained in it so reliable, and the method of putting the facts together so excellent, that we give it as follows in full:—

It is now 136 years since Margraff proved that alumina is a metallic oxide, sixty-two years since Wöhler first obtained metallic aluminium, and thirty-six since Deville's historical experiments produced the metal *en masse* for the first time. Modifications of Wöhler's and Deville's methods are still the chief of the processes for producing metallic aluminium, but as these methods involve the use of sodium they can never be the sources of the metal which, according to the enthusiastic journalists and leader-writers, is to be the material of our Atlantic liners, bridges, and locomotives in the coming "Aluminium Age." As far as our knowledge at present will allow us to prophesy, it is certain that the eventual method must be one of direct reduction. The first advance in this direction was the discovery made by Cowles that the use of the intense heat of the electric arc made it possible to reduce aluminium directly from its ores. Unfortunately, up to the present time it has been found that, in the absence of an alloying metal, the liberated aluminium absorbs carbon and is converted into a carbide, and so nothing richer than 80 per cent. aluminium has been obtained. Still there is every hope that at no very distant date it will be possible to overcome this difficulty and to obtain aluminium direct from the furnace.

Before proceeding to give some account of the chief value of aluminium in the arts and industries of to-day, a few words may be said about the physical properties and uses of the pure metal. Much misconception exists as to the purposes and conditions under which it would be possible to use this metal if produced as cheaply and in similar quantity to iron, and comparisons have been made which are certainly misleading. For the sake of more clearly explaining the matter, we give in Table I. the physical data of the two metals side by side. From

Digitized by Google

these figures it will readily be seen that, although aluminium is only one-third the weight of iron, it has little more than one-half the tensile strength of the best wrought iron, and only one-third that of mild steel, facts which would tell very materially against its replacing these metals in shipbuilding and for structural purposes. There are, of course, many circumstances in which aluminium might replace iron with advantage, but statements like the following are fallacious and misleading. "An Atlantic liner, built of aluminium, would have one-third the draught, and be propelled with the same engine power at double the speed that it is at present when built of iron; bridges built of this metal would be quite as strong as if built of iron, but would be only one-third the weight."

The chief demand for aluminium is at present—and probably always will be—in connection with its alloys. The use of the metal itself will be chiefly for light machinery, fittings for lighting and water supply, astronomical and scientific instruments, and art metal work generally. With copper, aluminium forms a series of beautiful alloys, varying in colour from bluish-white to red-gold and pale yellow, differing very widely in physical and mechanical properties. Those containing 60 to 70 per cent. aluminium are very brittle, glass-hard, and beautifully crystalline; with 50 per cent. the alloy is quite soft, but under 30 per cent. the hardness returns. The 20 per cent. bronze has a whitish-yellow tint, somewhat resembling bismuth. It is very brittle, and can be pulverised in a mortar. The brittleness of alloys above 11 per cent. prevents their use, but from 11 per cent. down to 1 per cent. they are most valuable. Their physical and mechanical properties render them useful for every variety of metal work, and the high price of aluminium has been the only restriction to their use hitherto. Table II. gives the range of tensile strength and density in castings of these alloys. In resistance to compression, A grade (10 per cent.) equals the best cast steel, its transverse strength or rigidity is about forty times greater than of ordinary brass, and its limit of elasticity equals that of steel of the same tensile strength and elongation. The results given in Table III. were obtained at Waterton Arsenal, U.S.A. One of the most valuable properties of these alloys is the fact that they are forgeable, and can be worked at a bright red heat as easily as wrought iron; all other bronzes are "hot-short." The rolling of sheets, rods, bars, and wire is done at a bright heat; only the finishing is done in the cold. A casting of B grade (which had a tensile resistance of 60,000lb. to 65,000lb. per sq. in.), with 20 per cent. elongation when rolled, showed 83,000lb. tensile resistance, with 30 per cent. elongation. These alloys retain their strength through a high range of temperature, a quality most valuable in a metal. Their resistance to corrosion, which is only a degree short of that possessed by gold and platinum, makes them invaluable to shipbuilders, marine, hydraulic, and sanitary engineers. This quality, combined with their colour, render them far superior to ordinary bronze for art metal work and statuary. The advent of smokeless powder, with its greater corrosive action on ordinary gunmetal and steel, is already causing military engineers to look round for a material to replace these metals in the artillery and small arms of the immediate future, and, in the peculiar combination of properties required, aluminium bronze is unapproachable by any other metal or alloy, and the solution of this question will undoubtedly lead to a great demand for these alloys. The aluminium brasses are made by combining the metal with copper and zinc yielding close-grain homogeneous and remarkably tough alloys. They are made in two grades. (See Tables IV. and V.) These alloys can be forged hot; their special casting properties, high corrosion resistance, and low specific gravity render them most valuable for hydraulic and engineering purposes. A propeller blade can be made of No. 2 brass at least one-third thinner than cast iron. The high elastic limit, surpassing that of alloys used hitherto for this purpose, would greatly lessen the chance of injury to the blades, in the event of contact with wreckage, whales, &c., at present a frequent source of danger and delay. In these days of fast steaming the weakening of blades by pitting and corrosion would be reduced to a minimum if made of aluminium brass.

This is but one of the very many instances which will readily present themselves to the minds of readers who will compare the physical data given above with that obtained from other alloys and metals which it will doubtless supersede as its qualities become more known. Not only is aluminium valuable in its alloys with copper, but it is of service in iron and steel working, giving sound castings, and increasing the tensile strengths. The alloys with zinc, nickel, tin, and manganese are of great interest, but space will not permit of anything beyond a brief note on a few of the properties and applications of a metal which may be truly described as one of the most valuable for the use of the engineer and general craftsman.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 29th April, 1890.

Iron.—The iron merchants of the capital, alarmed by the firm attitude of the manufacturers, have met in council and resolved to again put up the price of bars and joists to 160s. a ton. How this agreement is to be kept it would he rash to predict. Business continues slack; but this step on the part of the merchants may bring into the market buyers who were waiting for better terms, since it is sufficient to show that nothing is to be gained by waiting. It must, however, be admitted that the markets of the provinces are losing in life and vigour, and that possibly the manufacturers will be compelled to give way before long. The question is largely dependent upon the course of the coal trade. Without cheaper fuel the iron manufacturers can hardly reduce their prices. The state of the foreign trade relatively to that of the corresponding period of last year is shown by the Customs returns for the first three months of 1890. The imports consisted of—Pig iron, 33,863 (37,687) tons; finished iron, 5,912 (5,637) tons—and steel, 1,812 (2,283) tons. The exports consisted of—Pig, 57,748 (7,410) tons; finished iron, 20,578 (8,689) tons; and steel, 9,644 (7,843) tons.

Coal.—The coal question continues to disturb the industrial situation. For a moment it seemed that the supply had risen to the demand, and that prices were about to give way. But there is still a scarcity of the industrial sorts, and the colliery owners remain masters of the situation. There are no stocks at the pits. Every ton raised is sent away within twenty-four hours of its arrival at bank. In such circumstances lower prices are not to be thought of. Foreign coal is pouring into the country in increasing quantity. As next winter's trade will be begun without a ton of stocks at the pits the prospect is encouraging to the coal producers.

Metals.—The metal market is lifeless. Holders of copper warrants keep up their prices, which are now £6 above those current in the London market, but it is becoming evident that their game is nearly played out. The opinion of consumers seems to be that the average of copper prices in the second half of 1890 will be several pounds below that of the first half. Tin is but little dealt in, and prices continue to decline. Lead is unaltered, but spelter is lower, and the tendency is still downwards.

The Port of Dunkirk.—Year by year the trade of the port of Dunkirk steadily increases. Judging from the records of vessels entering and clearing in the first three months, the current year will compare very favourably with the last in this respect. The growth is especially noticeable in the trade with India and South America. The export of French manufactured goods shows a very encouraging increase, and augurs well for the future of industry in the northern district. When the works now in progress for providing more harbour accommodation are completed, a further impulse will, no doubt, be given to the trade of Dunkirk.

Commercial Treaties.—The Marseilles Chamber of Commerce, in reply to the Government circular, say they strongly deprecate the abolition of commercial treaties as ruinous for the carrying trade. The Marseilles tonnage, which in 1860 was 3,000,000, is now 10,000,000, and this increase the Chamber attributes to free trade.

BERLIN, 28th April, 1890.

Iron.—Within the last few days a clearly marked improvement has taken place in the iron trade of the Upper Silesian district. The efforts to re-establish the convention between the rolled iron manufacturers and the blast furnace owners having proved successful, the tone of the market has become stronger. According to the terms of this convention, which is to last three years, the makers of finished iron and steel are to pay the rates now current for pig so long as bars maintain their present price, and, more or less, according to a sliding scale agreed to as the price of bars varies. It is officially announced on the part of the finished iron and steel makers that they have sufficient work in hand to keep them going full time till the middle of August, and that consequently no fresh orders for delivery before that date can be accepted. The demand for joists is now very brisk. Prices have become firm all round. Foreign pig is less pressed for sale than it was a fortnight ago. The tone of the market generally is strong and buoyant.

Coal.—The effect of high prices in stimulating the production of coal is to be seen in the official records of mining in the Upper Silesian district for the first quarter of the current year. From these we learn that the output of the collieries in that locality amounted to 3,018,290 tons, against 2,501,220 tons in the corresponding quarter of 1889, an increase of more than 20 per cent. The coal market continues active, the demand for industrial use being unabated. Here, in Berlin, smiths' "nuts" are quoted 25s. 6d. to 27s.; blast furnace coke, 38s. to 40s.; and foundry coke, 38s. 6d. to 40s. 6d. a ton delivered.

Metals.—The metal market continues languid. Consumers buy only sufficient to provide for present necessities, and speculators stand aloof. Copper maintains its position with some firmness, but the amount of business done is small. Tin, too, is stronger in appearance; but though last week's prices are maintained, there is no increase of business to justify the improvement. Lead is less in demand and prices have given way slightly. Spelter continues its downward course. The decline is slow, but constant, and, judging from the tone of the market at Breslau, a considerably lower level will be reached before the movement is arrested.

Silver Production.—For a number of years past the production of silver in Germany has steadily increased, but last year showed a falling off relatively to 1888. The total production, which in 1886 amounted to a little under 300 tons, increased to 325 tons in 1887, and to 356 tons in 1888. Last year the quantity was only 341 tons. The shrinkage is attributed to the competition of trans-oceanic countries, which were formerly purchasers of European produce.

Glass Prices.—The German Glass Makers' Association, formed for the purpose of keeping up the price of lamp glass, has been broken up. This step had become necessary in consequence of the depressed state of the trade in that branch. The export trade has suffered severely because America, formerly our best customer, has become a large producer. Large stocks have accumulated at the works. A circular, emanating from forty-four glass bottle makers, has been sent round announcing a rise of 10 per cent. in prices to cover increased cost of fuel and raw materials.

The Imperial Revenue.—The revenue of the German Imperial Exchequer for the financial year 1889-90 exceeded the estimates by 78,239,381 marks, the principal increases being distributed as follows:—Tobacco tax, 196,170 marks; sugar tax, 786,590 marks; salt tax, 118,048 marks; brewing tax, 3,791,397 marks; stamps, 13,929,558 marks; Bourse tax, 11,951,707 marks; and private lottery tax, 1,908,826 marks. The revenue from the manufacture of brandy was 7,686,219 marks, and from the consumption of brandy 18,734,825 marks, below the estimates.

The Transcaspian Railway.—The receipts of the Transcaspian Railway for 1889 show a prosperous state of affairs. The entire cost of working the railway was £241,731, and the total carriage was 350,675 tons. The importation of Asiatic products into Russia has increased 127 per cent. in comparison with 1888, while the importation into Transcaspia, Turkestan, and the Central Asian khanates of sugar, manufactured goods, &c., has increased 94 per cent. It is also stated that in January, 1890, there were imported into Russia 4,078 tons of Central Asiatic cotton, and that the Russian factories will probably receive more than 48,387 tons in the course of the present year.

Women as Railway Servants in Russia.—The employment of women is about to be authorised on the Government railways in Russia. The Transcaucasian Railway Administration, having been invited to indicate the number of women which it believes can be employed, has replied that this number might amount to 25 or 30 per cent. of the total number of the employés.

The Forests of Europe.—The forests of Europe, according to a recent report of one of the State foresters of Prussia, cover the following areas:—Germany, 34,596,000 acres; Russia, 494,228,600 acres; Austria-Hungary, 46,951,700 acres; Sweden, 42,000,000 acres; France, 22,240,000 acres; Spain, 19,769,000; Italy, 9,884,570 acres; and England, 2,471,000 acres.

VIENNA, 28th April, 1890.

The Iron Market.—After a week of stagnation the accustomed activity has come back again to the iron market. The principal attention is being directed to constructional ironwork, for which the request is very great. There is great animation in Hungary. Tinned sheets have such a good sale as has not been the case for many years. Large orders, however, are only few at present, but all the works have so much to do that they do not feel any anxiety. The Prague-Dux and Dux-Bodenbach Railways are intending to give orders for 749 and 123 coal waggons respectively. The Alpine Montan Company will hold a general meeting this week. The balance-sheet shows a profit of 2·2 million florins, of which 1·5 million florins will be paid to the shareholders.

The Coal Market.—Threatening news comes from all the coal districts. The colliers are not willing to work for the wages paid up to the present, and strikes are advised from all sides. Principally in the Ostrau territory, from whence a great part of the Vienna consumption is obtained, the strike is a general one, and more than 5,000 men have ceased to work. The stock at Vienna will soon be consumed, and Prussian and Bohemian coals must be imported. Also in the Silesian and Galician works the labourers are very discontented, and there is a probability of a strike developing. The railways which carry large quantities of coals are completing their accounts for the year, and all show good profits. The Aussig-Teplitz Railway made a profit of more than 2·5 million florins, and pays a dividend of 13 per cent. The Bohemian Western Railway, which last year forwarded a quantity of 772,000 tons of coal and coke, 180,000 tons of iron, and 131,000 tons of ore, made a clear profit of 2·39 million florins, and will pay a dividend of 7½ per cent.

The Iron Gates.—The Hungarian Government are asking for contracts for the removal of the Iron Gates on the Danube. The work will comprise the blowing up of rocks at the rapids amounting in all to 212,000 cubic yards, two breakwaters containing 800,000 cubic yards of masonry and 137,000 cubic yards of paving, and a short ship canal. The works are to be finished in 1895, and bids must be accompanied by a guarantee deposit.

Petroleum Motors for Tramcars.—During the forthcoming Lands and Forests Exhibition in Vienna a tramway will be laid in the centre of the city, to accommodate a new car driven by a petroleum motor on the Daimler system.

DÜSSELDORF, 29th April, 1890.

Iron.—Notwithstanding the improvement which has appeared in the iron markets of Upper Silesia and, in some degree, in Belgium, the iron trade of this district continues languid. At least, there is languor in the markets for pig iron. Buyers restrict their dealings to the smallest possible scale, and as the merchants undersell the manufacturers, the latter receive but few fresh orders. This circumstance, however, is regarded with indifference, inasmuch as the whole of the production of the current year is already sold. The total production of pig in Germany, including Luxemburg, in the month of March amounted to 416,948 tons, against 380,500 tons in the same month of 1889. The total production in the first quarter of the year amounted to 1,153,040 tons, against 1,082,523 tons in the corresponding period of last year. There is still a fairly active current of business in finished iron and steel. Joists and plates are in good demand, and hoops continue to be bought freely, but wire and wire nails are neglected. Founders are not so busy as they were some weeks ago.

Coal.—For the present the coal market remains steady, but buyers are pressing hard for better terms. The demand continues good. It is said, on trustworthy authority, that the railway requirements for this district for the current year will exceed 2,000,000 tons. Last year the contracts amounted to 1,712,000 tons. The output of the Rhenish-Westphalian pits rose last week to 108,000 tons a day as an average. The total production of this locality in the first three months of the year amounted to 9,032,158 tons, against 8,756,225 tons in the corresponding portion of 1889, an increase of 3·1 per cent.

LILLE, 29th April, 1890.

Iron.—Much is being written and said about the firmness of the iron markets in this important district, and the inference invariably drawn is that trade is in a flourishing state. This conclusion is not correct. The firmness is due to the high price of coal, and not at all to an active demand. The truth is that business is languid. The demand falls so far short of the production that the manufacturers have called a meeting to discuss a proposal to imitate their Belgian neighbours, and to work but five days a week. But, after all, it may be doubted whether the firmness talked of really exists. The official quotations remain unchanged but concessions are made in another form.

Textile Manufactures.—Business continues fairly active in the linen goods trade. The demand has fallen off in the course of the last week, as usual at this season; but the amount of business done will compare favourably with that of the corresponding week of last year. A cheerful tone pervades the market. The textile trade of Rouen is disturbed by strikes. A conflict of this nature has occurred at the Union Commerciale de Tissage, an English company, whose mills are situate on the road to Caen. The woollen goods trade at Roubaix is slack compared with what it was a year ago, but the prospect is said to be encouraging.

Flax and Yarns.—The demand for home-grown flax continues brisk, and, as the stocks are being rapidly reduced, prices are very firm, with an upward tendency for the better sorts. Russian is in better demand. Prices are irregular, but on the whole they have not appreciably changed from what they were a week ago. There is not much doing in tows. Jute continues in brisk demand. A considerable amount of business is being done in yarns, sufficient to absorb the whole of the production. Prices are firm. Jute yarns are a little dearer.

Submarine Cable Manufacture.—The Société Générale des Téléphones is about to establish large works at Calais for the manufacture of submarine cables. The management will be entrusted to the firm of Ratier, who possess an important factory of a similar nature at Bezons, where they work solely for the Société des Téléphones. The site of the new works, to the east of the Carnot dock, covers an area of 17,566 square yards, of which some 6,000 will be roofed in. This is the first serious attempt to compete with the English firms, who have hitherto had practically a monopoly of this class of manufacture.

AMSTERDAM, 28th April, 1890.

New Margarine Factory in Holland.—Mr. Simon van der Berch, of Osch, already one of the largest margarine manufacturers of the Netherlands, will further extend his works by building a new factory at Rotterdam.

Navigation upon the Rhine.—The owners of all vessels navigating the Rhine have now to be provided with special licences, issued by the German and Dutch Governments for international use.

The Labour Strikes at Enschede.—The owners of factories at Enschede, suffering under the labour troubles have resolved to combine against the artisans. So long as the strikers do not resume their duties, the work in the factories where no strike exists will be confined to four days a week. All strikers who have not resumed work

Digitized by Google

within a week will not be taken on by any of the federated owners for a whole year. Every federated owner who violates these pledges shall forfeit 4,000 guilders. These strong measures appear to have been taken under the impression that the strikers receive help from England.

THE "ZONE" SYSTEM IN HOLLAND.—The State Railways Company will, it is reported, make a trial with the "zone" system upon their own lines. There will be three "zones" established, and both passenger fares and goods freights are to be materially reduced.

OYSTER CULTURE IN HOLLAND.—The prospectus of the Dutch Oyster Culture Company, Limited, has made its appearance. The object is to acquire, amalgamate, and combine certain oyster fisheries, carried on by different private firms on the Zuyder Zee and River Scheldt, under leases which will expire in 1915. The capital of the undertaking is close upon £200,000. In the last seven years the profits, including improvements on the different establishments, are stated to have been more than £100,000. The capital has all been taken up.

COPENHAGEN, 26TH APRIL, 1890.

BOOT AND SHOE MANUFACTORY.—A novel and extensive industry has just been inaugurated at Venersborg, Sweden —viz., a boot and shoe manufactory. The principal building is 90ft. long and 85ft. broad; the machinery is of the most approved style and the whole is lighted by electricity. As a beginning 170 hands are employed, and the daily production is about 700 pairs.

THE TON BREWERY AND MILLING COMPANY.—This company, at Stavanger, Norway, has now been reconstructed with a capital of 400,000kr. It is rather more than a year ago that the old concern suspended payments, although the assets, amounting to 802,000kr., showed a nominal surplus of 245,000kr. The net profits, while it has been worked in liquidation, amount to 42,000kr., but the annual net profits have amounted to as much as 80,000kr. The creditors will be paid in full, and there will, it is said, be a considerable surplus.

THE APATITE DEPOSITS IN SWEDEN.—The vast deposits of apatite in Northern Sweden have of late attracted a very considerable amount of attention, and hopes are entertained that they may prove of great industrial importance. The apatite is especially met with in the Norrbatten district, in the famous Gellivara iron ore mountain. Some five or six miles to the south of the Gellivara mountain is another huge mountain, which is called Gellivara Dundret, and which consists entirely of gabbro. During the year 1888 somewhat extensive examinations were made in this neighbourhood, with the result that deposits of apatite were met with in the gabbro, not only in the Dundret Mountain, but in the neighbouring mountainous districts for a number of miles along the Lulea-Gellivara Railway. This gave rise to some very sensational rumours about the apatite deposits, which, it was stated, had already passed into the hands of English capitalists. This is apparently not the case, but a Government commission was appointed to thoroughly investigate the matter. A report can be expected before long.

ENGINEERING IN SWEDEN.—Most of the larger engineering establishments in Sweden continue to be well employed. Orders for steamers are still coming in, especially from Russia, and those works which have made rolling stock one of their specialties are also doing a large trade. Prominent among the latter is the Kockum Engineering Company, Malmo, which has orders in hand from several railway companies. The Atlas Works, at Stockholm, are also very busy with railway carriages and tramcars for the home market and for export. Five large cars for the Abo Tramway Company, Finland. The construction of the tramcars contains several novel features; the bottom part is made of steel plates, and the springs are also of a new kind. To the town of Tula, Russia, six tramcars have been delivered; these have separate smoking compartments at the ends. For the Stockholm New Tramway Company eight cars are in course of construction. For the State railways a large number of goods carriages are in hand. The Mora-Venern Railway Company has ordered eight and the Gefle-Dalu Railway three bogie carriages, 60ft. long, and having eight wheels. Another firm that is doing remarkably well is the Laval Separator Company, at Stockholm. Their profits during 1889 amounted to close upon 400,000kr. This is not a bad result for a company with a capital of only 1,000,000kr.

MADRID, 28TH APRIL, 1890.

AN IRON ORE LAWSUIT.—A long pending lawsuit about the property of the San Antonio Iron Ore mine has ended in an agreement that the party keeping the mine shall pay £164,000 to the other. The mine is supposed to contain one of the largest deposits near Bilbao of Campanil ore.

SPANISH COGNAC.—One or two of the largest wine merchants of Jerez, in presence of the ungrounded disfavour with which sherry wine of old fame is now regarded in England, have turned their attention to cognac making with their good and strong wines. Their cognac has already acquired a good name, and it is fetching better prices than the finest French qualities.

MATURING OF WINE.—Experiments have been recently published on the action of light in ageing new wines. By exposing layers of the young wine in vessels covered with coloured glass to the direct action of sunlight, the flavour and quality of the wine are said to be considerably improved.

BEETROOT SUGAR IN SPAIN.—No less than ten factories for making beetroot sugar have already been established in the province of Granada, and thirteen more are to be erected in consequence of the success of those already at work. The soil and climate of that part of the country are highly suitable for the cultivation of the beet. The roots grow to exceptional sizes, and give a considerable yield of saccharine matter. These favourable results have only been obtained from one year's experience, and before the cultivation is pronounced a success and extended, the effect on the soil of several years' growth of the beet should be ascertained.

THE POPULATION OF SPAIN.—The Madrid Geographical and Statistical Institute, publishing some of the first results known as to the census taken at the end of 1887, reports that the total population of Spain at that date was 17,550,216, as against 16,634,345 at the census of 1877, this representing an increase of 951,901, or 0·54 per cent. per year; whereas in the period from 1860 to 1877 the increase was at the rate of only 0·35 per cent. per year. The Geographical Institute attributes this slight improvement to the public tranquillity which has prevailed since the close of the Carlist insurrection and to the better hygienic condition of the large towns. In the poorer of the provinces, such at Soria, Teruel, and Almeria, which are badly off for means of communication, the population has either diminished or has remained stationary; but there has been a great increase in the provinces of Huelva and Biscay, where industry has been developed so much lately, though the most densely populated provinces are those of Barcelona, Valencia, Madrid, and Corunna. The returns as to emigration from Spain during the ten years from 1877 to 1887 are not yet prepared, but the preliminary report mentions, as might have been expected, that it has increased very much.

NEW YORK, 19TH APRIL, 1890.

THE IRON AND STEEL TRADE.—The trade is generally very unsettled, and prices are lower in nearly all lines. In pig iron the pressure to realise, on Southern irons especially, has been very great, and prices are about a dollar per ton lower. The three grades can now be bought at $16, $17·50, and $18·50 per ton, and Southern irons bring about a dollar less. The impression is that prices are now about as low as they are likely to be during the present year, and that though some brands are at present bringing considerably more than others they will soon fall to the lower level, and the market will remain stationary for some time. In manufactured iron the prices are correspondingly irregular. A fair amount of business in small lots has been done. The decline in pig iron is of some assistance to manufacturers, but the trade is unsatisfactory and orders are only to cover present needs. Prospects are good for a large summer consumption, and as soon as prices settle down again a very active demand is expected. Bar iron is quoted at 1·9c. per lb., plates at 2·15c., and angles 2·25c., with an advance of from ·15c. to ·25c. for steel. Steel rails are dull, but prices hold their own. Sales of small lots have been made at $34 per ton, but prices are still considered too high for the placing of large orders. In other shapes steel is unsatisfactory. Quotations for billets vary from $30 to $31·50 per ton.

THE COAL TRADE.—The anthracite trade is demoralised The demand for domestic sizes is very light, but manufacturing and steam sizes can be readily sold. The large companies are doing all they can to preserve the prices, but the rates offered by the individual operators have to be accepted or the trade would vanish. As long as the low rates were confined to current orders, the state of things was not so serious, but coal is now being sold for future delivery at the same low rates, and the outlook is, therefore, not a very pleasant one. There is hardly a possibility of any improvement occurring in the situation until the 1st of August, but if the combination holds until that time there will be an active trade for the rest of the year.

CANAL AROUND NIAGARA.—The construction of a ship canal around Niagara Falls by the United States Government was favourably received in the United States House Committee on Railways and Canals. About $10,000 was ordered for the expenses of a Board of Designation, and $1,000,000 to begin the work. The Board will consist of two army engineers, two civil engineers, and one citizen, all appointed by the President. The canal will be along one of the surveyed lines, and its total cost will be $23,000,000. The route will be twenty-three miles long, and the locks 400ft. in length, by 80ft. in width.

THE GRAIN INDUSTRY AT BALTIMORE. Two new elevators are to be built in Baltimore to supply the needs of her growing grain trade. One will have a full working capacity of a million bushels, and it will be supplied with all the latest improvements for elevator work. It will cost $300,000. The other elevator is to be built principally for the storage of oats, and will supply a long-needed want as regards storage and weighing facilities. It will have a capacity of from 250,000 to 300,000 bushels, and will be built at a cost of $150,000.

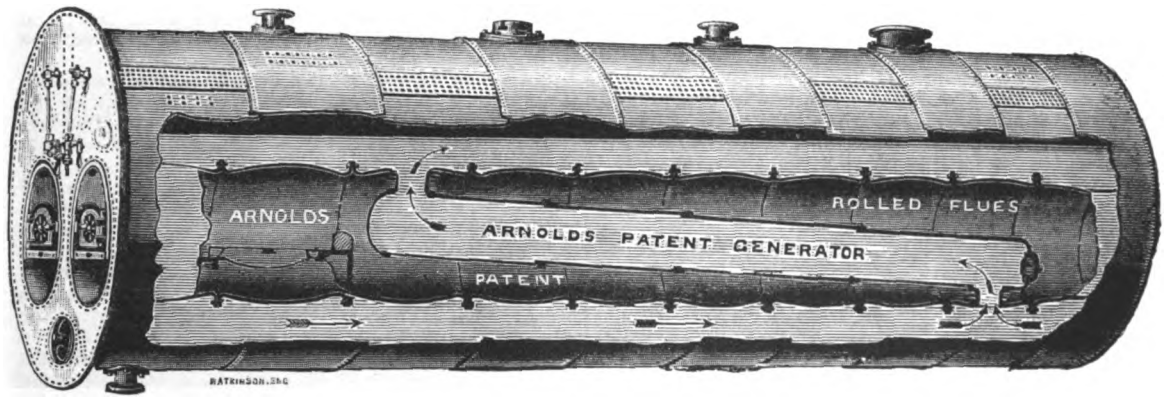
THE UNITED STATES' TORPEDO BOAT "CUSHING."—The report of the trial board of the "Cushing," built by the Herreshoffs, has been made public. After her trial on the measured mile the boat was taken outside and run around Block Island at a speed of about 16 knots. The boat behaved well with sea abeam and on either quarter. The boat was then loaded with sufficient coal for twelve days and again taken outside. There was considerable sea on but no water was taken aboard. The following is an abstract of the log: Speed, 22·5 knots; steam pressure, 245lb. per sq. in.; pressure in first receiver, 100lb. per sq. in.; in second receiver, 40lb. per sq. in.; in third receiver, 5lb. per sq. in.; vacuum, 24in.; revolutions, 370; revolutions of air and feed pumps, 130; revolutions of after blower, 500; air pressure, 2½in.; revolutions of forward blower, 825; air pressure, 3in.; revolutions of circulating pumps, 360; horse power, 1,720; coal, lbs. per hour, 3,446; coal per horse-power, 2lb. per hour; grate surface in use, 76·6 sq. ft.; coal per sq. ft. of grate per hour, 45lb.

STRIKE IN THE BUILDING TRADES.—About four years ago the first determined effort of the members of the American Federation of Labour was made in Chicago. During that winter, by agitation and organisation, probably 60,000 men were made ready to strike for an eight-hour day on the 1st of May, 1886. The movement seemed irresistible, when the explosion of the Haymarket bomb settled the matter temporarily. Since that time various attempts have been made to lessen the hours of labour, but no great success has been attained. The Confederation of Labour has confined the eight-hour battle for this spring to the building trades. Of these the most powerful—the Bricklayers' Union—has had the eight-hour day for two years, and several smaller unions also have it. The fight was begun in Chicago, on the 7th inst., by the Carpenters' Council, which includes representatives of about 6,000 men. They demand an eight-hour day, an advance of wages from 35 cents to 40 cents per hour, the establishment of an apprentice system, and a permanent arbitration committee to which all disputes shall be referred and whose decision shall be final. The association representing the contractors has refused to recognise the Carpenters' Council. The other building trades are fully organised, and will join the movement on the 1st of May. The trouble will probably be confined to these trades alone, as there is less possibility of filling the places of the strikers, and the federation is in better shape to carry on a winning fight with only a portion of its members on strike.

A HUGE COMPANY.—Negotiations are in progress for the sale of the Chicago Cattle Yards to an English syndicate for $30,000,000. The terms of this contract are as follow:—(1) A cash payment of $15,000,000; (2) bonds in the new company for $10,000,000; (3) the issue of preferred stock to the present stockholders in the sum of $5,000,000. The effect of the sale will be to send princely dividends to Europe, and to that extent it will not be hailed with any tempestuous evidences of approval by the people of Chicago. Thirty-five years ago less than 200,000 food animals of all kinds were slaughtered there annually, while last year 1,763,310 cattle, 87,392 calves, 4,211,867 hogs, and 1,121,154 sheep (7,183,724 animals) were thus disposed of. These figures tell a story of a business the growth of which is without a parallel. The sale of the yards will be the business sensation of the year on the American continent.

PHILADELPHIA, 18TH APRIL, 1890.

CAST STEEL GUNS.—The second cast steel gun, of open-hearth steel, has not been a success, just like that of a year ago. In that test the gun withstood ten service rounds, but showed signs of undue expansion and flaw, the significance of which was disputed. The second test was a repetition of the first, both in the number of rounds and the result. The expansion was doubled, and three serious flaws developed. As the Bessemer steel gun went to pieces at the first round, cast steel guns are for the present out of the question.



THE "BROWN" WIRE GUN.—The "Brown" segmental wire gun has been very successfully tested on a small scale. The dimensions are: Calibre, 1in.; length, 44in.; diameter at breech, 4in.; at muzzle, 3in.; weight, 70lb. It consists of 24 segments of steel wound with steel wire of $\frac{1}{16}$in. in diameter at a uniform tension of 100lb. At the breech there are 22 layers, and at the muzzle 9. There is no lining tube, the rifling—one turn in 25 calibres—being cut on the inner edges of the segments. The total pressure over the powder chamber is 7,000lb. per sq. in., and the pressure necessary to burst the gun would be about 150,000lb. per sq. in. The success of this gun has satisfied the inventor's friends, and a 5in. gun has been ordered and will be completed in July. The rapidity of construction possible in this design is one of the great advantages claimed for it, and if a 5in. gun, built in three months without even a special plant to do the work, equals in penetration the other guns now used in the navy, it is thought that it may supplant the forged guns, which require about three times as long for completion. The 1in. gun sent a steel projectile through three 1in. plates, developing an initial velocity of 2,570ft. per second, with a chamber pressure of 50,000lb. per sq. in. The wire for winding this gun was made at the Carpenter Steel Works, Reading, Pa., from a special grade of crucible steel costing $1 per lb. It showed a tensile strength of 328,000lb. per sq. in., with 4 per cent. elongation, and 3·32 per cent. reduction of area.

THE OKRA PLANT.—Considerable attention is being directed to the okra plant, an annual of South American origin, which, heretofore, has been known chiefly as an excellent vegetable for soups. It has recently been discovered, however, that this plant has an excellent fibre, and an inventor asserts that he has devised a process for extracting okra fibre at a cost not exceeding 1c. per lb. It is believed that okra fibre, especially if extracted at this price, will largely displace jute, and it is also likely to come into competition with henequen.

IMPROVED STEAM BOILER.

CONSTRUCTED BY MESSRS. WILLIAM ARNOLD & Co., ENGINEERS, BARNSLEY.

THE LATE PARIS EXHIBITION.

THE official report of the Executive Council of the British Section at the late Paris Exhibition has recently been issued, signed by Sir Polydor de Keyser, President, and Mr. H. Trueman Wood, Commissioner Delegate.

The first step taken by the Council on its election was to form a guarantee fund. Altogether £16,800 was subscribed, but fortunately none of this has been required, for the balance-sheet shows a small surplus. The expenditure up to the 18th of March amounted to about £29,000.

The chief source of revenue has been the money received for space, a charge for which was made at the rate of 5s. per square foot, the only exception to this charge being in the Agricultural Gallery, where there was no flooring, the charge being 2s. 6d. per square foot, and in the Photographic Section, where 2s. 6d. was charged for wall or screen space. One of the largest items of general expense was of necessity that for the decoration of the courts, which was under the honorary superintendence of Mr. Donaldson. The decorations in the Liberal Arts Section and in the Agricultural and Food Galleries were on a less expensive scale. Other heavy items of expenditure were the supplying of the necessary plant and fittings in the Machinery Hall, and the reception of exhibits at the commencement and their despatch at the close of the Exhibition.

The Council think it right to draw attention to the manner in which the space allotted to Great Britain, as to other foreign nations, was divided up. This division placed the exhibits of foreign countries at a great disadvantage as compared with those of France.

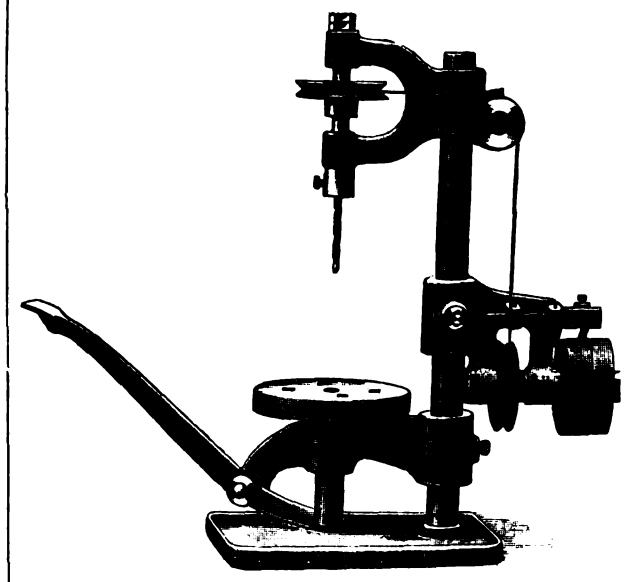
A total number of 673 exhibitors occupied space in the Machinery Hall, Industrial Gallery, Liberal Arts, Indian Palace, Food Products, and Agricultural Gallieries, and there were in addition to these, 47 exhibitors in the Social Economy Section, and 429 in the Fine Arts Section—of whom 297 were artists and 132 private lenders—making a grand total of 1,149 British exhibitors.

The awards granted by the French authorities consisted of Grands Prix, gold, silver, and bronze medals, and honourable mentions. The list of awards was given in *Industries* of the 4th and 11th of October, 1889. Throughout the Exhibition the average of awards was 50 per cent. In the British Section, it was 90 per cent., or in the Industrial Section alone, 120 per cent.—*i.e.*, 752 awards amongst 673 exhibitors.

For the accommodation of Indian exhibitors a special building was erected on a space of ground allotted for the purpose by the French Administration. The greater part of the cost of the erection and maintenance of this building was defrayed by the amounts paid by exhibitors for the twenty shops or stalls into which it was divided, and by a contribution from the Indian Tea Districts Association, in return for which the verandah of the building was placed at their disposal, and was turned into a restaurant for the sale of Indian tea. The deficiency, a little over £350, was made up out of the general funds. By the regulations of the Exhibition, the sale of objects of genuine Oriental manufacture was permitted in the Indian Pavilion.

The arrangements for the storage of empty cases have always been a difficulty at International Exhibitions. Following the example of the Royal Commission of 1878, the Executive Council determined to make their own arrangements for this part of the work. Accordingly they rented a piece of waste ground near the Exhibition, and employed Mr. Humphreys to erect on it an iron shed, his estimate for the purpose being lower than those of French contractors for the cheapest possible construction. As the cases were emptied at the commencement of the Exhibition they were removed as rapidly as possible, and stored in such a way as to ensure their being readily and quickly delivered at the close of the Exhibition. The delivery commenced the morning after the Exhibition was closed, November 7th, and was rapidly carried through without difficulty. The exhibitors were charged a fee, varying according to the size of each case, from 2s. 6d. a cubic yard downwards. There were very few complaints of loss or damage, and in these few instances the loss was made good. The work of clearing the galleries commenced on the 7th of November, the morning after the close, and within a fortnight, with the exception of the Industrial Gallery and the Machinery Hall, the British Section was practically cleared of exhibits. The whole of the British Section was cleared out before Christmas, including the Fine Arts, where great care of course had to be taken in the packing of the exhibits.

THE LEEDS EXHIBITION.



APATHY has given place to interest among the people of Leeds with regard to the International Exhibition which is to be held in that town from the 21st of this month to the end of October. The project did not at first obtain that amount of local support which was anticipated, but within the past few weeks circumstances have occurred which point to the complete success of the undertaking. The greater interest now manifested by Leeds business people in the Exhibition has led Mr. J. Davis, the promoter and manager, to telegraph to his Continental agents not to accept further proposals from intending exhibitors. Should it be found necessary, the management will erect further accommodation for local and national requirements. The venture is in the hands of a syndicate formed of gentlemen in prominent positions, and, though Leeds is not asked to contribute towards the expenditure, it will reap great advantage from the Exhibition.

As previously announced in *Industries*, the Exhibition is to be held at the depôt of the Leeds Rifle Volunteers, which is less than half a mile from the railways running into the town, and within easy reach of several excellent tram and 'bus routes. Five acres of grounds are available for the undertaking. Possession has been taken of the site, and much progress made in the work of preparation for the opening. The Exhibition will deal with matters engineering, mining, industrial, and commercial. The several sections embrace machinery, metallurgy, the production of precious metals, electricity, foods and drinks, architecture, rural industries, manufactures, education, fine arts, chemical industries, decorative art, hygiene, clothing, music, and domestic appliances. A special section is to be devoted to the question of the housing of the poor, with the object of assisting in the development of the best schemes to effect improvement in the condition of the dwellings of the labouring classes. Another specialty will be a "Leeds Court," under the control of a local committee. The centres of industry and places to be represented at the Exhibition include Bradford, Keighley, Pontefract, and other Yorkshire towns, London, Manchester, Liverpool, Birmingham, Newcastle, Bolton, Wolverhampton, Southport, Ferryhill, Blackburn, Wallsend, Keswick, Brighton, and Cornish towns, while many applications have been received from the Continent. During the course of the Exhibition competent jurors will be empowered to award medals and diplomas in those cases where the exhibits are deemed to be of sufficient merit. In the industrial department it is intended to have a series of exhibits illustrating a selected number of trades and handicrafts in operation, while in the engineering section a good display of steamship models is promised.

The Exhibition building will consist of wooden erections, having felt and glass roofs, and forming a series of parallel courts intersected by gangways 6ft. or 7ft. in width. The majority of the contracts connected with the preparation of the Exhibition are in the hands of local tradesmen. The woodwork is being erected by Messrs. Ives & Co., of Shipley. The building is to be coated with the specialty of the Anti-Flamme Company, London, for safety against fire, though there will also be available the hydrants of the Leeds Corporation and the appliances of Messrs. Shand & Mason, and probably those of Messrs. Merryweather & Co. Illumination lamps are to be supplied by Messrs. J. Russell & Co., Leeds; and the decorations, &c., will be fitted by Messrs. Pigott Bros., London. Arrangements are being made with the railway companies for the running of excursion trains and the issuing of cheap tickets. Mr. Davis, who has promoted the Exhibition, was connected with the enterprise at York last year, and had charge of the Anglo-Danish Exhibition at South Kensington in 1888.

PARKINSON'S DRILLING MACHINE.

IN the accompanying illustration we show a small drilling machine now being placed on the market by Mr. J. Parkinson, tool maker, Union Works, Chester Street, Bradford. It is intended for drilling holes up to ¼in. dia-

meter, and will admit work 7in. thick. The table on which the work is held is fed up to the drill by the front lever shown in the illustration, and the drill may be driven either by the cord and power pulleys, as shown, or by treadle. The height of the apparatus is 1ft. 10in. from the base to the top of the drill.

ARNOLD'S STEAM BOILER.

WE illustrate above the latest form of the now well-known steam boiler with rolled flues and circulating water chamber, manufactured by Messrs. William Arnold & Co., Victoria Works, Barnsley. There were two novelties in Messrs. Arnold's boilers, viz., the shape of the segments of the flue and the use of a water chamber within the flue in the place of the ordinary cross tubes. At first the ends of the water chamber were joined direct to the flue, but in the latest form, as illustrated above, the joint is made through the interposition of a flanged ring, so that freer expansion and contraction can be reckoned on. We understand that Messrs. Arnold have put down a large number of installations of this type of boiler, and that they give great satisfaction as regards heating power and economy.

A FRENCH SUBMARINE GUNBOAT.

IN *Industries* for 1st March, 1889 (page 209), we gave a short account of a submarine gunboat built in France, called the "Gymnote," and which had attracted considerable attention in England. We mentioned several experiments which had been made, but since that time considerable modifications have been effected in some of its parts. Recently further experiments have been carried out, from the reports of which we now give a few ex-

Digitized by Google

tracts. After the first experiments it was found necessary to modify the accumulator cases, and after patient research, fragile, non-conducting substances being set aside, cases were at length produced which have given entire satisfaction, made of a special kind of guttapercha. After having made a preparatory trip to ascertain that all was working properly on board, and taken some very satisfactory plunges, the boat re-entered the harbour and had her accumulators charged. At noon of the second day she was hermetically sealed by closing the panel giving admission to the interior, which was not to be opened till four hours later.

The "Gymnote" was accompanied by a steam launch, which had instructions to keep out of the way any boats which might come up. On getting to the place selected for the trials everything was put in order for the plunge, and at a given signal it slowly descended, and remained at a depth of 2 metres 50 centimetres below the surface of the water. It was found easy to remain at that depth, with variations of about 20 centimetres. The length of the course was estimated by the number of turns of the screw, and in this way it was known when the limit of deep water was reached. The "Gymnote" then returned to the surface, passed round a mark, and took a plunge in the opposite direction, and made various evolutions to show her powers of steering and of remaining at a given depth. She did not leave on the surface any trace of her passage, and is quite invisible when painted grey, but on the occasion of these trials she was painted white in order that her course might be seen under water. Altogether, the experiments were most successful, and seem to mark a decided advance on anything that had hitherto been attempted.

SHIPBUILDING NOTES.

On the 19th ult. the steamer "Kasara," built by the Ailsa Shipbuilding Company, Troon, for the British India Steam Navigation Company, made her trial trip on the Forth of Clyde. The distance between the Cumbrae and Cloch lighthouses and back again was accomplished at the rate of 14·1 knots per hour, the speed guaranteed being 13¼ knots. The dimensions of the vessel are:—Length, 240ft.; breadth, 34ft.; depth, 25ft. The engines, which are of the triple expansion type, are by Messrs. Dunsmuir & Jackson, Govan. The cylinders are 25in., 40in., and 65in. diameter, and the stroke 42in. The revolutions averaged 88½ per minute, and the power developed was over 2,200 i.h.p. Steam is supplied from two large double-ended boilers working at a pressure of 160lb. per square inch. The fittings include Weir's patent feed-heater evaporator and pumps, Bow McLachlan's patent steam steering gear, &c. The vessel has been supplied with an installation of the electric light by Messrs. William Harvie & Co., Broomielaw, Glasgow.

On the 19th ult. there was launched from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington-Quay-on-Tyne, a screw steel steamer, which has been built to the order of Messrs. Thomas Stephens & Sons, of London. She is of the following dimensions:—Length, 260ft.; breadth, 36ft. 8in.; depth, 19ft. 3ft. This steamer has water ballast right fore and aft on the cellular system, and is fitted with all modern improvements for the rapid loading and discharging of cargo. The engines, which are to be supplied by the Wallsend Slipway and Engineering Company, Limited, are of the triple expansion type, having cylinders 24in., 34in., and 54in. diameter, by 36in. stroke. On leaving the ways the vessel was named the "Manuka."

On the 19th ult. Messrs. Richardson, Duck & Co. launched from their shipbuilding yard at South Stockton a steel screw steamer of the following dimensions:—Length, 270ft.; breadth, extreme, 37ft.; depth, moulded 19ft. 5in.; and tonnage, gross, about 1,900 tons. The vessel has been built to the order of Messrs. Farrar, Groves, & Co., of London. She has a raised quarter-deck, a long bridge extending to stern, and a double bottom on the cellular principle, extending fore and aft, for water ballast. She will be fitted with four steam winches, steam steering gear, stockless anchors, and all the latest improvements for facilitating loading and discharging cargo. Her engines have been built by Messrs. Blair & Co., Ld. As the vessel was leaving the ways she was christened "Girdleness."

On the 20th ult. Messrs. Laird Brothers, Birkenhead, launched the first of two torpedo gun vessels which they have built to the order of the Government of the Argentine Confederation. This vessel (the "Espora") may be described as being of the "Rattlesnake" type, but has higher speed, lighter draught of water, and several structural improvements embodied in her design. Her dimensions are:—Length over all, 210ft.; beam, 25ft.; depth, 13ft. 6in.; and tonnage, 615 tons. She will be fitted with twin screws driven by two sets of triple-expansion engines having a collective power of 3,250 h.p. The hull is built entirely of steel, with a ram stem, and is divided into upwards of thirty water-tight compartments. The coal bunkers are arranged to afford protection to the machinery, and each set of engines and each pair of boilers are in separate compartments. The armament will consist of Nordenfelt quick-firing guns; two 14-pounders mounted one on each side of the forecastle, one 8-pounder at the after end of the poop, two 3-pounders at fore end of the poop; two Gatling guns; and five torpedo tubes, one in the bow and two on each broadside, fitted for discharging the new 18in. Whitehead torpedo.

Notices of Meetings.

Society of Engineers.—Monday, May 5th, at 7.30 p.m. A paper to be read on "Breakwater Construction," by Mr. F. H. Cheesewright, Assoc.M.Inst.C.E.

Society of Chemical Industry.—Monday, May 5th. Papers to be read: Mr. Watson Smith, "The Dinsmore Process"; Messrs. Cross and Bevan, "Some Considerations in the Chemistry of Bleaching"; Mr. M. L. Griffin, "Moisture in Paper Pulp."

The Institution of Civil Engineers.—Ordinary Meeting, Tuesday, May 6th, at 8 p.m. Paper to be read: "The Screw Propeller," by Mr. Syd. W. Barnaby, M.Inst.C.E.

Iron and Steel Institute.—Annual Meeting, May 7th, 8th, and 9th. Papers to be read: "On a New Form of Siemens Furnace, arranged to recover Waste Gases as well as Waste Heat," by Mr. John Head, London; "On the Robert-Bessemer Process," by Mr. Lynwood Garrison, Philadelphia; "On Some Critical Points in the Iron and Steel Manufacture," by Monsieur F. Osmond, Paris; "On the Carburization of Iron by the Diamond," by Professor C. Roberts-Austen, F.R.S., London; "Notes on the Action of Aluminium on Iron and Steel," by Sir Henry Roscoe, M.P., F.R.S., London; "On Aluminium in Carburetted Iron," by Mr. W. J. Keep, Detroit, U.S.A.; "On the Changes in Iron produced by Thermal Treatment," by Dr. E. J. Ball, London; "On Certain Chemical Phenomena in the Manufacture of Steel," by Mr. W. Galbraith, Willingworth; "On the Estimation of Phosphorus in the Basic Siemens Steel Bath," by Mr. W. Galbraith, Willingworth; "On the Rollet Process for producing Purified Castings," by Monsieur Rollet, Paris.

The Institution of Electrical Engineers.—Thursday, May 8th, at 8 p.m. Discussion on the following paper: "On a Lightning Guard for Telegraph Purposes and on the Protection of Cables from Lightning," by Dr. Oliver Lodge, F.R.S.; and paper to be read, "The Treatment, Regulation, and Control of Electric Light by the Legislature and the Board of Trade," by Major P. Cardew.

Chemical Society.—Thursday, May 8th, at 8 p.m. Extra Meeting. Exhibition of apparatus, &c.

The Junior Engineering Society.—Friday, May 9th, at 7.30 p.m. Paper to be read: "The Slide Valve and Radial Valve Gears," by Mr. W. J. Tennant.

PRICES CURRENT, 30th April, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.		Best. £ s. d.

„ English Sheet	14	7	6	„	14	10	0
Tin: Straits	91	15	0	„	92	5	0
„ Australian	92	0	0	„	92	10	0
„ English Ingots	96	15	0	„	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper has been much firmer during the past week, owing to the continued scarcity of Chili bars offering for prompt delivery and the better demand for consumption. Values are consequently higher. On the 23rd quotations for Chili bars were £48 7s. 6d. to £48 15s. cash. Moderate sales took place during the next few days at higher rates, £49 to £49 5s. being paid on the 28th for cash metal. To-day's quotations are £49 2s. 6d. to £49 10s, with quiet business reported. Manufactured has been advanced to £62 sheets, £65 bottoms, and there is more inquiry.

Tin: There has been a rapid rise in tin during the week, but the advance has not been maintained. The rise in silver, and the firmer market in the Straits, caused prices of foreign tin to advance from £90 to £90 10s. cash on the 23rd to £93 10s. to £94 on the 28th, after which values receded, quotations to-day being £91 15s. to £92 5s., with but little business doing.

Lead: Values are a shade easier than last week, with small demand.

Spelter has been rapidly advanced, chiefly by buying on merchant account. The stocks are small, and prices higher abroad than in England, where the low price for spelter is consequent upon the slackness of the galvanisers.

HOME INDUSTRIES.

LONDON, 1st May, 1890.

The Money Market.—The money market continues fairly easy in default of any great demand and in presence of a plentiful supply. Rates of discount, on the other hand, show a hardening tendency, principally through the drain of gold to the Continent. The Bank refused to sell any more French gold, and, as the French demand has now to be satisfied by the open market, the extent of the drain for that country cannot be exactly gauged. The German demand has been considerable this week. The stock markets have been very active. The announcement of an agreement as to the basis of silver legislation in America has caused a rapid rise in all American securities, as the increase of the currency must enliven trade and bring about a higher level of prices. The advance in the quotations of American securities has been quite sensational, and the revival of speculative activity has spread into all the markets. Securities depending directly on silver have been most prominent, such as Indian rupee paper and Mexican railway stocks, but the advance has been so general that it is impossible to single out individual stocks. The promised inflation of the American currency will certainly promote trade between this country and the States.

Companies.—The following companies have been registered since our last report: Buenos Ayres and Pacific Railway Equipment and Goods Depôt Co., Ld., with a capital of £700; Central African Co., Ld., with a capital of £50,400, to acquire land, mining rights, &c.; Persian Bank Mining Rights Corporation, Ld., with a capital of £1,000,000; Pullenger, Cheverton, & Co., Ld., with a capital of £10,000, to carry on the business of leather dressers, &c.; The Government and General Contract Co., Ld., with a capital of £100,000, to execute public works, &c.; The Pentremaur Colliery Co., Ld., with a capital of £10,000; Hanley & Co., Ld., with a capital of £100,000, to carry on the business of brewers at Oxford; The Burmah Explorations, Ld., with a capital of £200,000; Hartley & Aspinall, Ld., with a capital of £5,000, to acquire a boiler making business; Madagascar Concessions and Exploration Syndicate, Ld., with a capital of £5,000; Geffard Inventions Trust, Ld., with a capital of £6,528, to acquire certain patents; Cam Portland Cement Co., Ld., with a capital of £20,000; Stapleford & Sandiacre Water Co., Ld., with a capital of £20,000; Madagascar (Sumtava and Antalaha) Forests Syndicate, Ld., with a capital of £25,000; Vishnu Gold Co., Ld., with a capital of £200,000; Leedham & Heaton, Ld., with a capital of £25,000, to acquire a tool manufacturing business; Kelsey Patent Adjustable Hat Syndicate, Ld., with a capital of £6,000, to acquire certain patents; The Severn Tweed Co., Ld., with a capital of £150,000, to acquire certain mills; Mundesley-on-Sea Waterworks Co., Ld., with a capital of £3,000; The Knysna Mines, Ld., with a capital of £42,000; The Parker Gold Mines, Ld., with a capital of £150,000; Kingston Engineering Co., Ld., with a capital of £25,000; Imperial Oilcloth Co., Ld., with a capital of £60,000.

Hydraulic Lifts.—Messrs. Archibald Smith & Stevens have received instructions to erect one of their "Reliance" hydraulic lifts at the Badminton Club Chambers. They are also erecting similar lifts at Ashley Mansions, Victoria Street, Westminster; at chambers in Throgmorton Avenue, for Mr. J. Morris; at the Blue Hart Court, for Messrs. Cosh & Co.; at Chesterfield Gardens, for Mr. J. W. Beer; and for Messrs. Carruthers Brothers, of Luton.

Swan United Electric Light Company.—The directors of this company have decided to pay an *ad interim* dividend at the rate of 6 per cent. per annum for the six months ending 31st March, 1890.

Railways.—The gross receipts of the 23 principal railways in the United Kingdom for the week ending April 20 amounted, on 16,159¼ miles, to £1,297,712, and for the corresponding period of 1889, on 16,031 miles, to £1,328,911, an increase of 128¼ miles, or 0·8 per cent., and a decrease of £31,199, or 2·3 per cent., comparison being made with the week which included the Good Friday traffic.

The Iron and Steel Institute.—The Iron and Steel Institute some time ago decided to hold their autumn meeting in the United States at the invitation of the American Institute of Mining Engineers. The meeting will be held in New York on the 1st, 2nd, and 3rd of October, under the presidency of Sir James Kitson, after which an adjournment will be made to Pittsburg, where an international meeting will commence on the 5th of October. The chief bodies represented at this congress will be the American Institute of Mining Engineers, the Iron and Steel Institute, and the Verein Deutscher Eisenhüttenleute. Subsequently the visitors will attend the sittings of the American Institute of Mining Engineers. A large number of excursions have been arranged to most of the places of interest in the United States.

The Institution of Mechanical Engineers.—A distinguished company assembled at the annual dinner of this Institution, which was held last night, at the Criterion Restaurant, Piccadilly, Sir Michael Hicks-Beach being the principal guest. The engineers of the Forth Bridge came in for a lion's share of the compliments.

Prizes for Threshing Machines.—In connection with the Doncaster meeting of the Royal Agricultural Society, a first prize of £100, a second prize of £50, and a third prize of £25 will be offered for the best combined portable threshing and finishing machine, to be worked by steam, and adapted to the preparation of corn for market. The width is not to exceed 4ft. 8ft. inside the frame, and the width of drum must not be more than 4ft. 6in. The points, representing 100 per cent. of perfection, will be valued as under: Clean threshing, 30; clean shaking, 10; cavings free from corn, 5; chaff free from corn, 6; chaff free from cavings, seeds, and dirt, 5; straw unbroken, 5; corn uninjured, 15; cleanness of delivery from machines, 2; perfection of finishing, 5; construction and convenience of working, 6; power in proportion to results, 5; economy of attendance, 4; price, 2.

Electrical Engineering.—The steamship "Ilimoff," recently launched by Messrs. Craig, Taylor, & Co., of Stockton, for Mr. Alfred Suart, of London, has been fitted up with an excellent installation of electric lighting by Messrs. Hayward, Tyler, & Co., hydraulic and electrical engineers, London. This firm has supplied a large number of similar plant to Mr. Suart's steamers. The wiring is carried out on the double-wire system, and the wires are thoroughly cased and protected throughout the ship. Messrs. Hayward, Tyler, & Co. have also supplied all the pumping apparatus and valves for the delivery of petroleum on board these vessels.

MANCHESTER, 1st May, 1890.

The Iron Trade.—The tone of the market is very flat, and little business is offered. It is hardly possible to gauge prices at all, as quotations are only nominally given as a guide to buyers. There is still a disparity between the price of warrants and makers' quotations. A good deal of iron is, however, in the hands of middlemen, who are indisposed to hold it, and prices are, therefore, generally weakening. In bar iron the same tendency is observable, and in some cases makers are anxious for specifications. It is true that they are in many cases well booked with contracts, but the rapid rate of production and the diminution of demand have caused a little anxiety for the present. The price for bars is nominally £7 10s. per ton, but rather lower rates have been taken. Steel plates are not so readily sold at present, as boilermakers, although mostly well off, are not so pressed for business as they were a few months ago.

The Merchandise Marks Bill.—At the quarterly meeting of the Manchester Chamber of Commerce, held on the 28th ult., the proposed amending Bill introduced by Mr. Broadhurst into Parliament was condemned unanimously, with the exception of the clause appointing a public prosecutor. It was pointed out that the Bill, if it became law, would act prejudicially to the merchant who in many cases by prompt payments and advances enables the small manufacturer to establish himself in business.

The Manchester Ship Canal.—Despite the strenuous opposition of various authorities the House of Lords Select Committee has passed the Bill promoted by the Ship Canal Company. The alteration of the tidal openings proposed has been sanctioned, subject to the protective and penal clauses usual in such cases.

The Ribble Bill.—A Committee of the House of Commons has approved of the Bill of the Preston Corporation sanctioning the loan of £220,000 to complete the dock works as recommended by the Board of Trade Commissioners. It is reported that the depth of water at the bar has been considerably deepened, and it is proposed to commence running a regular service of steamers to Glasgow and the Isle of Man.

Type Writing.—The Manchester School Board has recently added type writing to the list of subjects upon which examinations are held. The Technical School Committee also include it in their list of subjects, and the first examination was held on the 28th ult. Ninety candidates came forward and were given sample letters to write. It may be here stated that the evening classes in commercial subjects promoted by the Manchester School Board have been very successful, over 300 students being at present on the books.

A New Bank.—A new bank is about to be established in Manchester by a limited company, under the title of the Lancashire Bank, Limited. The capital is fixed at £2,000,000, and a fair proportion of it is practically subscribed. The reasons for this new step are that the various existing local banks have paid good dividends in the past, and that there will be a great extension of business when the Ship Canal becomes an accomplished fact.

The Linen and Jute Trades.—Since our last week's report was written a somewhat unexpected activity has been noticeable in the wholesale distributing branch of the local dry goods trade, as far as the heavy departments are concerned. This is an unusual occurrence at such a period as the present, as fancy goods are now supposed to be the class of fabrics most suitable for the requirements of the season. Under ordinary circumstances this undoubtedly is so. The weather of late has, however, been so remarkably unseasonable that the ordinary condition of affairs has been reversed, and hence we find that fabrics like linens have had a fair run. As far as agents are concerned, however, there has not been much doing, and orders are difficult to obtain. This is somewhat discouraging, especially in view of the fact that certain classes of goods, such as black and finished hollands, are cheaper to-day than can be remembered for years. There is not much doing for shipment. As far as the South American market is concerned the recent further advance in the gold premium at the Plate tends to disorganise business, which was bad enough before, and with remittances so backward as they are at present new orders are things to be shunned rather than sought for. Yarns for the Lancashire market are in fair demand. In the manufacture of unions considerable quantities of linen and jute yarns are still consumed here.

GLASGOW, 1st May, 1890.

Pig Iron.—The sharp decline in prices has had the effect of bringing to grief one of the oldest houses in the trade. The return to low prices has, it is said, attracted the attention of foreign speculators, and it is reported that there has been considerable buying on account of German bankers in anticipation of an advance at no distant date. It may be, however, that in Germany it is difficult to find investments for capital in industrial enterprises. The report of purchases for abroad in this connection steadied the market in the beginning of the week, and there was a slight reaction upwards.

Utilisation of Waste Shale.—For many years the country immediately to the West of Glasgow has been greatly disfigured by heaps of waste shale, covering many acres. Many experiments have been tried to utilise this material, the mere removal of which, it was stated sometime ago in court, would cost upwards of £40,000. Hitherto the experiments have not been successful; but now, it is said, the problem has been satisfactorily solved. A company is being formed for the purpose of making the waste material into bricks. It is also intended to recover the ammonia which is present in small quantity in the refuse.

Glasgow Harbour Tunnel.—At the first half-yearly meeting of the shareholders of this company, a report was submitted showing that the total expenditure up to 31st January was £14,407 10s. 4d. Of this sum, Parliamentary expenses took £5,979 16s. 8d., and purchase of land and compensation, £8,007. The estimated expenditure during the current half-year was £90,000, and subsequent half-years £75,643 10s. 5d. The work of constructing a tunnel under the harbour was commenced on the south side of the Clyde in January last, and the 80ft. shaft has been sunk to a depth of about 25ft. The work on the north side will be commenced as soon as possession of the ground is obtained at Whitsuntide.

The Boundaries Bill.—This Bill, which is full of importance for Glasgow, both industrially and otherwise, seems likely to pass the preliminary stages before the close of this week. A large number of members of the Glasgow Corporation have been in London in connection with the Bill, but the examination of witnesses on behalf of the promoters was cut short on Monday in consequence of the manifest leaning of several members of the committee. The only point which practically remains to be settled is the question of terms; the ring of burghs outside the city, having enjoyed a low rate of taxation, claim to be exempt from certain of the city taxes for a period of years. The passing of the Bill will make Glasgow a homogeneous whole in point of municipal government, and will, other things being equal, diminish the rate of taxation within the city itself, when the period expires during which the differential rate for the annexed districts is to obtain.

Shipbuilding—A number of steamers which were laid down last autumn on speculation, and which are nearing completion, are being offered in the market at greatly reduced prices. In one case a cargo steamer has been offered at £8 10s. per ton, or 20s. below the quotations given a month ago, by Messrs. Angier Brothers; and in another case 25 per cent. has been taken off the price offered two or three months ago.—An order for a 46ft. steam launch has been secured by Mr. Thomas Orr, Jun., Greenock.—Messrs. James & George Thomson have converted their business into a limited liability company. The capital of £250,000 has already been subscribed and fully paid up. Under the auspices of the Realisation and Debenture Corporation of Scotland, Limited, they now ask for subscriptions to an issue of £150,000 mortgage debenture stock bearing interest at 5 per cent. The security for this debenture stock is the property of the company at Clydebank, valued by Mr. Bryce Douglas, of Barrow, and Mr. Smellie, of Glasgow, at £308,000.

(From our own Correspondents.)

LIVERPOOL, 30th April, 1890.

Technical Education.—Some three or four years ago a large committee was formed with the object of furthering the cause of technical education in Liverpool and the district, and arrangements were made for holding various classes for the practical instruction of the working men in the different parts of the city. The results, however, are not at all satisfactory, and the practical men of the committee are strongly objecting to the *modus operandi* and the consequent results. A large number of the committee appear to be quite satisfied so long as a number of articles such as paper knives, brackets, letter racks, &c., prettily carved in wood, are shown to them as the work of the students. As this kind of training is really not technical education, but more of a recreation, indulged in by both boys and girls, there is no doubt just cause for complaint.

The Liverpool Engineering Society.—After the adjourned discussion of the paper on the "Efficiency of Gas Engines," by Mr. Thos. L. Miller, which takes place at the next meeting, the present session will be closed. At the last meeting, Mr. F. Hudleston, Assoc.M.Inst.C.E., was elected president for the next year. Arrangements are now

Digitized by Google

being made for the summer excursion to the Manchester Waterworks in course of construction at Thirlmere, the Forth Bridge, the works of the Liverpool Electric Supply Company, and other places of interest.

SHEFFIELD, 30th April, 1890.

Iron and Steel.—A very quiet tone prevails throughout the whole of this district in the iron trades, although makers still continue to dispose of the whole of their production. One very large firm in this district, who consume 1,000 tons of coal every day in the production of pig iron, are quoting pig f.o.b. this week at 53s. 6d. The steel works continue to be active in all branches. Messrs. Charles Cammell & Co. are engaged upon the production of some extra long marine tunnel shafting for the English Government. The tubular form of shafting is yielding plenty of work. Messrs. Cammells are prepared, if necessary, to bore lengths of 100ft., and to guarantee accuracy.

Coal and Coke.—There is very little change to report at present. Fuel of all kinds is rather quiet, although there is a fair demand for steam-raising fuel. House fire coal still maintains the recent advance; a reduction is, however, shortly expected. Coke continues in fair demand.

Labour.—One of the greatest difficulties manufacturers have to put up with here is the constant demand for an advance in wages from their employés. Never was skilled labour paid better than now.

New Railway.—The contractors for the Beighton and Chesterfield branch of the Manchester, Sheffield, and Lincolnshire Railway are pushing the work forward with great vigour. A considerable portion of the boundary is fenced in.

Leeds Association of Foremen Engineers and Draughtsmen.—At the meeting on Thursday, the 24th inst, it was resolved that the association should meet weekly on Thursday evenings for the perusal of technical papers and for consulting the valuable reference works in the library, the ordinary meeting being held on the last Thursday in the month as usual. The new president, Mr. Alfred Atkinson, then gave his inaugural address, taking as his subject the history of the association from its formation in 1865. He afterwards gave an interesting account of his visit to the anniversary festival of the London Association of Foremen Engineers and Draughtsmen, and also of his visits to the works of Messrs. Maudslay, Son, & Field, to Woolwich Arsenal, and to the Mint.

NORTH STAFFORDSHIRE, 30th April, 1890.

A Birmingham-Liverpool Ship Canal.—Little has been heard for some time of the projected ship canal between Birmingham and Liverpool, but it is now understood that the scheme has been diligently pushed, and that considerable progress has been made in working out the details. A survey has been made by Sir James Brunlees and Mr. McKerrow, in co-operation with Mr. Edwin Clark. Among other alterations in the plans suggested by Sir J. Brunlees and Mr. McKerrow, the width is to be increased to 72ft. This will give a capacity sufficient to accommodate seagoing vessels of 300 tons burden, or barges of 400 tons. Instead of locks, the continental system of hydraulic lifts will be largely used. The estimated cost of the canal is between £2,500,000 and £3,000,000. The route is from Birmingham, through the Black Country, to Wolverhampton; thence, in a line almost due north, to Stoke-on-Trent, through the heart of the Potteries, and then, in a north-westerly direction, to Kidsgrove, Wheelock, and Winsford, where the canal will meet the Weaver at a place called the Top Flashes. The distance from Birmingham to this point is sixty-one miles.

An Improved Packing.—Mr. W. J. Mayger, of Burton-on-Trent, is introducing into this country an improved square packing for piston rods and valve stems. The packing consists of successive layers of cotton duck firmly cemented together by an elastic lubricating compound, and its mode of manufacture is such that the edges of the cotton fabric are brought into contact with the rods. Thus the friction is entirely on the ends of the threads, and, consequently, the wear is very slow. Some of this packing has already been supplied to the London and North-Western and the Midland Railways.

LEICESTER, 30th April, 1890.

Wool Spinning and Yarn Trades.—There is on the whole an improvement in the local wool market. Since last report a very fair amount of business has been done, and prices are firmer and more settled. The local spinners do not buy as freely as those elsewhere, and seem to have less confidence in the present quotations. Skin-wools sell very freely and at full rates. As the consumption is increasing a very fair turnover is being made. Spinners are getting busier, but there is no pressure. Cashmere yarns are slow in demand and under the average.

Hosiery Trade.—There is a gradual though slow improvement in this industry. The influx of orders increases and more workpeople are employed. The improvement is felt in almost all branches, and there are some good orders on offer, but prices are not very settled. Buying as a rule is very steady, and the wholesale houses seem loth to speculate.

Boot and Shoe Trade.—Though there is a slackening in the orders to hand there is sufficient business on the manufacturers' books to keep all hands fully employed. Scarcity of labour is the principal want, and to meet the demands many houses are running overtime. There is no doubt that the present activity in the trade will last till Whitsuntide. Leather merchants are doing a good steady business, but users buy very closely and the market offers no inducement to speculative buying.

Colour Printing.—Mr. Thomas Taylor, engineer and machinist, Leicester, is introducing an appliance called the "Radiant," for printing in several colours from a single forme at one impression. It is intended to be fitted to the inventor's "Favourite" platen printing machine, but it can be fitted equally well to any platen printing machine which has an ink duct as long as the diameter of the distributing disc. No new operations are introduced by its use, and no reduction is required in the working speed.

SWANSEA, 30th April, 1890.

Coal in South Wales.—For some weeks past boring operations have been carried out on the burrows about two miles east of the Prince of Wales Dock, Swansea, and coal has been struck at a depth of 80ft. An extensive area of land has been secured from the Earl of Jersey, and it is confidently anticipated that some twenty-six seams of coal will be eventually tapped, including all the well-known Aberdare measures. In addition to the land area, the workings will be extended out into the Channel. The available quantity of coal is estimated at sixty to seventy million tons.

Tinplates.—The Old Lodge Tinplate Works have commenced operations, and five mills have been re-started at Abercarne. The edict of the Tinplate Workmen's Association, that the first week in May should be observed as a stop week, is not likely to meet with unanimous obedience so long as the stocks continue to be reduced at the rate of 23,000 boxes per week. American advices are reassuring, and the recent reductions in the price of bars are enabling makers to better meet the views of buyers.

Labour Disputes.—The employés of the Taff Vale Railway Company, in seeking to fix the maximum hours of duty to ten per day except for shunters in busy yards, and signalmen at important boxes, whose maximum should be only eight hours, would appear to be studying as much the safety of the public as their own convenience.—The strike at the Cardiff works of the Tharsis Copper Company still continues, and a settlement has not been brought nearer by the introduction of new hands from Bridgwater who have left work.—Some 500 men and boys at Tredegar struck work against a charge of 6d. each weekly for their conveyance between Tredegar and the Pochin collieries, two and a half miles distant.

BARROW-IN-FURNESS, 30th April, 1890.

Hematite Iron.—The depression is more pronounced in the hematite pig iron trade this week, as although arrangements have been made to blow out several furnaces there is no improvement in prices, which are steady at 53s. 6d. per ton for warrants. Stocks of the latter have been further reduced during the week to the extent of 5,578 tons, and from the beginning of the year they have been decreased 38,050 tons. There are 47 furnaces in blast and 32 standing idle.

Steel.—There is next to no trade doing in steel, either in Bessemer or Siemens-Martin. Although large orders are still held the outlook is anything but assuring, and prices show a gradual depression. Heavy rails are at £5 per ton, ship plates at £7 10s., and angles at £6 15s. per ton. Tinplate bars are down to £5 5s. per ton. There is a movement amongst those makers who are not working on the sliding scale to effect a reduction in the wages of steel workers, in order to meet the altered condition of the market.

Shipbuilding.—Orders for shipping are not coming to hand from either home or foreign sources, but it is probable that local builders will be favoured with some large contracts which can be secured when the value of building material has been further reduced. In the meantime builders and engineers are very busy in every department.

Shipments.—During the past week shipments have been on a large scale. The total exports of iron and steel from West Coast ports were 27,201 tons, compared with 20,636 tons in the corresponding week of last year. The shipments this year to date have been 345,741 tons, compared with 354,930 tons in the corresponding period of last year, a decrease of 9,189 tons.

MIDDLESBROUGH, 30th April, 1890.

Pig Iron.—Since last report the tendency has been downward, with sudden fluctuations. Yesterday the market was firmer, however, and is now much the same as it was a week ago. Merchants ask 45s. 6d. to 46s. per ton for makers' No. 3 G.M.B. prompt f.o.b. delivery. Cleveland No. 3 warrants are 45s. cash, buyers offering 44s. 9d. per ton. The makers' price is 50s., but merchants shipping iron prefer to draw upon warrants. Grey forge is to be had at 46d. 6d. West Coast hematite is quoted at 54s. 10d. cash; East Coast hematite is quoted at 65s. to 70s., but with West Coast so cheap there is practically nothing doing in them.

Shipments of Pig Iron.—The shipments are improving as the season advances. Compared with last month they are better, but not so with the same month last year. Up to the 28th inst. the month's shipments are 66,689 tons, as against 53,006 tons to the 28th of last month. The shipments are disappointing when compared with those of last year, which for the month of April up to the 28th amounted to 92,918 tons.

Manufactured Iron and Steel.—Manufactured iron and steel are as dull as they were last week, and prices are drooping. The North Eastern Steel Company have stopped for the first time since they started for want of specifications. Of new orders there are none, and even inquiries have ceased to be made.

Wages.—Notwithstanding the sinister aspect of business, demands are being made for advances in wages. The Anderston Foundry men demand 15 per cent. on the top of a similar advance a short time ago, and the stevedores who are engaged in loading pig iron and unloading iron ore at the wharves demand 12½ per cent. advance. In a falling market neither demand is likely to be conceded.

NEWCASTLE, 30th April, 1890.

The Coal Trade. The demand for gas and steam coals is fairly active, but for household coal there is very little inquiry, and consumers may now count on getting their supplies at somewhat lower rates than they have been paying lately.

The Timber Trade.—There is still a lack of animation in the timber trade, but the season for importations is commencing, and the present state of dulness at the docks and wharves will soon be changed to one of considerable activity. In the meantime, the saw mills are very busy, and likely to continue so for some time.

Marble Works.—Messrs. Emley & Sons' marble work Gateshead, are very fully employed just now, the orders in hand being mostly from local builders whose requirements have, for some time past, been rather heavy.

Shipbuilding.—The evidences of slackening trade in the shipbuilding industry are daily becoming more strongly manifested, and there is now scarcely a building yard on the river which has not one or more empty berths. Sir W. G. Armstrong, Mitchell, & Co. have three berths vacant at their Low Walker yard, and Messrs. Hawthorn, Leslie, & Co. have four. At Messrs. Schlesinger, Davis, & Co.'s establishment, however, matters are much worse, as in that case only one berth out of seven is occupied, and the vessel on the stocks is nearly completed. Messrs. Wigham Richardson & Co. have still a large reserve of work besides the vessels in progress, and their establishment is likely to be kept busy up to the end of the year. The Palmer's Shipbuilding & Iron Company have ten vessels on the stocks at their Howden and Jarrow yards, and they are now busily preparing to lay down two line-of-battle ships at the latter establishment. Messrs. Readhead & Sons, of Tyne Dock, have their berths well filled; but the Edwards Shipbuilding Company have only two vessels on the stocks, four of their berths being vacant. The prices of steel and iron material having fallen to the extent of about 30s. per ton since the opening of the year, builders are now able to offer lower quotations for tonnage; but notwithstanding this incentive to speculation, new orders are scarce, and are likely to continue so until an all-round lessening in the cost of production enables builders to bring their prices more within the range of customers' requirements.

BELFAST, 30th April, 1890.

Shipbuilding and Engineering.—Business in all the yards both in Belfast and Derry is very good. A large number of ships are on the stocks, and although no new orders are reported, there is enough work in hands to ensure constant employment during the summer months. The boiler makers are fairly busy, and several large land boilers are in hand.

The Belfast Drainage Scheme.—The drawings and specifications for the pumping engines for the new Belfast main drainage scheme have been prepared, and are at present before the Council. The main engines will be two in number, and will be exact duplicates of each other. They will be of the compound horizontal condensing type, having cylinders 10in. and 18in. in diameter, by 3ft. stroke. The surface condensers will be so arranged that the sewage in the discharge pipe shall act as the cooling medium. The piston rods will be carried through the back ends of the cylinders, and will actuate the pumps by means of bell crank levers. The pumps themselves will be of the plunger type, the barrels being unbored. The engines will run ordinarily at 24 revolutions per minute, but will be capable of working up to 30 revolutions when required. In addition to the main engines, there will be a centrifugal pump, for use after a heavy rainfall. This pump will be driven by a separate compound condensing engine, coupled direct to the driving shaft of the pump, and will run at 150 revolutions. The estimated cost will be about £14,000, and the annual working expenditure, £800.

The Linen Trade.—Business in the linen trade still continues slack, and an improvement is much to be desired. Sales of yarn have not been large, but prices still remain firm. The stocks of handloom goods are poor; in fact, this industry is almost at a standstill. The supply of home-grown flax is nearly run out, and the foreign markets are not yet opened.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 2ND MAY, 1890.

THE HORSE-POWER OF MARINE ENGINES.

AT the end of the session of 1888, the Council of the North East Coast Institution of Engineers and Shipbuilders issued a Report on what they called the Normal Indicated Horse-power of Marine Engines, and sent it to the various Engineering Institutions for discussion. We gave a *résumé* of the Report shortly after its publication (see *Industries*, Vol. IV., page 642), and at the same time invited the opinion of our readers regarding it, but little or no interest seems to have been raised in the matter. Various incidental expressions of opinions have been given, but it cannot be said to have been fully discussed. In October, 1888, it was taken up by the Institution of Engineers and Shipbuilders in Scotland, but the general results of the discussion could not be considered favourable. Mr. Dyer, who introduced the subject, pointed out that in every department of scientific investigation the tendency has been towards the displacement of all merely nominal or qualitative measurements by exact quantitative measurements; and he was of opinion that until fairly convenient means were devised for measuring the brake horse-power, it would be better to be content with the power as given by the indicator. Dr. Kirk, the President of the Institution, was strongly against the proposal contained in the Report of the Council of the North East Coast Institution. He asked: "For what purpose was it desired to have a formula to ascertain the nominal horse-power of an engine? Was it for a commercial purpose? In all his experience he had never known the machines sold by nominal horse-power. Was it to be a substitute for the present rational method of computation in calculating the power of an engine? He thought that in the coming days of technical education, and even before those days, in the days of more general education, it would be simply deplorable to use a formula which, at the very best, put in an artificial state the practice of the present time. Now that practice was continually changing, and the ordinary rational formula, which covered all the calculations at present in use for discovering the horse-power of marine engines, could cover all those changes. And what more could a formula do? Perhaps it might be said that it would be useful in estimating the cost of engines. Then, he would say, the man who so used such a formula would soon be in the Bankruptcy Court." Dr. Kirk then went on to say that, although in some respects the proposed formula was an improvement over the old ones, "he thought a formula of the kind under discussion was of no use. The only thing which could be said in favour of nominal horse-power being computed was that it was in use for registration, and the Merchant Shipping Act required that every vessel with engines over 100 horse-power was bound to carry at least one first and one second class certificated engineer. They could not expect that the Parliament which passed that measure was composed of experts, and so the measure was passed by men who knew nothing at all about the question of determining the horse-power of an engine, for which no rule was wanted. He thought that nominal horse-power was fast passing into disuse, and was dying a natural death."

After such an authoritative opinion it might have been thought that the question was settled, but the recent paper by Mr. Weighton, read before the North East Coast Institution, has again brought it to the front. It is well known that Mr. Weighton took an active part in framing the rule, and it is a pity that his paper was not read along with it instead of nearly two years afterwards. He says that in many cases the scope and intention of the rule has been totally misunderstood, and he thinks that this was largely due to the fact that the Report appeared in a very condensed form. His paper was read at the request of the Council, in the hope that, by entering at greater length than was possible or desirable within the confines of a report into an exposition of the principles upon which the rule is based, such misapprehensions would be corrected and future ones obviated. Mr. Weighton still believes that, if properly understood, the rule will prove of great value, not only to shipowners, underwriters, and non-technical men generally, but that it may also be found of very considerable value in the practice of marine engineers themselves. We must admit that Mr. Weighton shows great ability in his paper, but we must also confess that we think his ingenuity might have been expended on a more useful purpose. He begins by inquiring if there is any need for a rule to take the place of the now obsolete horse-power? and, if there is a need, what is it intended to represent, and for what is it to be used? To the first of these questions he replies that there is a need—a very great need—to be able to estimate the comparative values of different engines and boilers, and different combinations of engines and boilers; and he points out that marine machinery may be said to have two kinds of value—(1) value to the owner, and (2) cost to the builder—and that these two values are not synonymous, and do not necessarily run parallel with each other for all sizes of even one type of machinery. He explains that it is the first kind of value with which the paper is chiefly concerned, although the relation of the second to the first is touched upon briefly. He then goes on to show that what is required is a rule which expresses, in convenient mechanical units or terms, the value to the shipowner, and states that from this point of view the rule must *not* represent the actual i.h.p. which will be, or is expected to be, developed in every case. It *may* give the same result as the actual i.h.p. in many cases, but it is not necessary that it should do so; in fact, it would not serve the purpose intended if it did do so in all cases; and Mr. Weighton complains that it is chiefly in this respect that the rule has been misunderstood. He says that it has been assumed by many that the intention was to produce a formula which would give the actually developed horse-power in all cases, and because it failed to do so when applied to particular cases, it has by some been condemned as worthless, and he is very much pained to find it said that the ordinary means of arriving at the powers of engines by the indicator was on the whole more correct and preferable in every way. To remove, what he considers, such deplorable misunderstandings as to the aim and meaning of the rule under discussion, he deals with this particular phase of the matter at some length. This, however, was surely unnecessary, at least to anyone possessing any knowledge of the subject, for nobody would have imagined that the i.h.p., or even the brake horse-power, was in itself a sufficient measure of the efficiency of one engine as compared with another, at least from the shipowner's point of view. As

Digitized by Google

Mr. Weighton points out, "to compare the values of two engines by comparing their actual i.h.p. is—in the absence of identical working conditions—like comparing the values of the numerators of two fractions without first reducing them to a common denominator. Any given size of engines can be made to indicate vastly increased power by simply running them at a greater number of revolutions, or by increasing the period of admission of steam in the high-pressure cylinder, or by both of these means combined; any given size of boiler may be worked very much beyond its normal power by forcing the fires. But this increase of power is obtained at the cost of increased wear and tear and increased fuel consumption, unless, indeed, it be possible to introduce some compensatory arrangements or devices in the higher power engines and boilers." He adds that, "apart from the question of the possibility of introducing such arrangements, it is distinctly to be borne in mind that no elements beyond size of engines and boilers, and working pressures, can possibly be included as factors in any general rule," and he illustrates his remarks by some arithmetical examples.

We must confess, however, that, notwithstanding all his ingenuity, Mr. Weighton has in our opinion failed to make out his case. We fully admit that the proposed rule is a great improvement on any of the old ones, because its data are more in accordance with modern practice, and also because it takes the boiler into account; but, notwithstanding all this, we think that, in the absence of the brake power, the indicated power is the most useful and most correct measure, alike to owners and builders. An expression which contained all the variables affecting the efficiency of a steamship, or even a marine engine, from the owner's point of view would be a very complicated affair, and when Mr. Weighton puts forward one, as he does, he only tends to give a wrong opinion, and lead to satisfaction with results which are capable of great improvement. The efficiency of the engines includes that of the boilers, the steam, and the mechanism, but each of these again have many factors depending on design, materials, arrangement, workmanship, pressure, speed, and many other things, and, among others, the skill and attention of the engineers and the stokers, and the efficiency from the owner's point of view extends over the whole life of the ship or engines. It is almost as absurd to measure this efficiency from a number of indicator cards extending over a year or more, as it is to do so from a single one. But these immeasurable factors are, in reality, the "personal equations" of the builders, and on them depend to a large extent their commercial success, for no shipowners would return to them with orders when they found that their work, while giving a high efficiency on the trial trips, very soon cost a great deal for repairs or renewals. It seems to us, therefore, that the common sense of the matter is simply this. The i.h.p. is the nearest approach to the actual power which we can conveniently obtain, and when a ship is wanted the naval architect should say to the engineer what number of i.h.p. he requires. The owner should further stipulate that the conditions under which the engines are to work are normal, that the materials and workmanship are good, and the design simple, and allowing of repairs. For the rest he must trust to the skill of the engineer and those who are advising him, and this cannot be measured by any factor in an equation, for it requires to be supplemented by careful working and skilful management to produce real economy. We think this matter should be settled once for all, and as some of our readers may differ from our conclusions we shall be glad to publish their opinions.

THE PROPOSED GREAT TOWER IN LONDON.

The promoters of the Great Tower for London announced some time ago that they would offer prizes of 500 guineas and 250 guineas for the best and the second best design and estimate for a tower of not less than 1,200ft. in height. The specification indicated a preference for steel, but left the question of material an open one. Should steel be employed, it was stipulated that the structure should be designed to withstand a maximum wind pressure of 56lb. per square foot, the stress on the steel being stated at a maximum of 7½ tons per square inch. The ultimate stability of the whole should be assured under an assumed pressure of double the above amount. The questions of the number of storeys and the type of lifts were left open. The following are the jurors:—Sir Frederick Bramwell, Sir Benjamin Baker, Sir Edward Harland, M.P., Professor Alex. B. W. Kennedy, Mr. Charles Liddell, Mr. J. F. Moulton, M.A., Q.C., Mr. Thomas Verity, F.R.I.B.A., and Mr. E. H. Carbutt, chairman. The promoters requested that the plans should be accompanied by a general elevation $\frac{1}{240}$th of the actual size of the proposed erection. Eighty-six designs in all have been sent in for competition. Of these, however, only sixty-eight fall within the scope of the specification. All of the designs, are now on exhibition to the public free of charge in the Hall of the Drapers' Company, Throgmorton Street, London, E.C. It would be premature to pronounce any opinion upon the merits of the designs, as the jurors have not yet delivered their award. The designs exhibit considerable range of style. The Eiffel Tower design, more or less modified, appears in several of them. Some are apparently suggested by the conventional pictures of the Tower of Babel, others are ecclesiastical towers whose proportions have simply been expanded, others are magnified screws, while some are glass furnaces of monstrous size. The lure of £500 has brought into the net not a few curiosities. There is the Chinese lantern design, the design on half a sheet of note paper, the factory chimney design, the gigantic mast design, the candelabrum design. More than one of the designers aim at a tower of 2,000ft. in height. One of these proposes that the base of his tower shall occupy sixty-four acres, or about twenty times the area of the Albert Hall. The competitive drawings have come from many quarters. Though the names of all of the competitors are not given, Jamaica, Canada, Constantinople, Hamburg, New York, Philadelphia, Paris, and Naples are represented. It is expected that the award of the jury will be made in a few days.

THE REPORT ON THE NAVAL AND MILITARY DEPARTMENTS.

The Report of the Royal Commissioners on the Civil and Professional Administration of the Naval and Military Departments, and the relation of those Departments to each other and to the Treasury, which has been so long expected, was recently issued, and although it contains many important proposals, and exposes many absurdities in the present methods of doing business, it does not seem to have attracted much attention, either on the part of the public or of the members of the Services concerned. We can easily understand why this should be, for the public, as a rule, only takes an interest in such matters when there is either a great panic or a grave scandal. As to the members of the Services, the *Times* recently remarked that "if the long-suffering taxpayers of this country are going to wait until a report of this kind is actively taken up by the persons whose failures it exposes, they will wait a very long time. The wasteful muddle of administration with which the country is burdened suits the existing administrators perfectly, otherwise it would not exist. They only want things to be left as they are, and they are wise enough in their generation to know that the less they discuss the Report, the better their chance of getting it quietly shelved. It is for the House of Commons and the country to see that the Report shall not be shelved." We think so too, and, therefore, we propose to give some of its most important points. We may say that the Report and its appendices are well worthy of careful study by all interested in the Navy and the Army, as they explain fully the present system of administration, without an understanding of which it is impossible fully to follow the recommendations of the Commissioners. They found, on entering on the inquiry entrusted to them, that a great mass of information bearing upon it had already been collected by Commissioners and Committees which had previously investigated the administration of the Navy and Army. Summaries of much of this is given, together with statements descriptive of the systems of administration prevailing in some foreign countries, which were drawn up by the Naval and Military Intelligence Departments. Not content with this, however, the Commissioners formulated certain questions to past and present Ministers and professional officers, who from experience were best able to form a just judgment on the various points submitted to them. The questions thus issued grouped themselves under two principal heads:—(*a*) Measures required to ensure closer administrative harmony between the naval and the military services; (*b*) matters of internal departmental administration, and the responsibility of departmental chiefs and their immediate subordinates.

The replies to these questions showed that a great divergence of opinion exists on some points, and serve to illustrate the difficulties of the task with which the Commissioners were called to deal. They state that much of the evidence on which their report is founded was given on the understanding that it would not be made public, and they consider that the publication of much of it would be most inexpedient. This may be so, but it places the public at a great disadvantage in judging of the evidence. The subject matter of the Report has been arranged under the following heads: (A) The measures required to ensure full and sufficient administrative harmony between the two Departments; (B) the internal administration of the Admiralty; (C) the internal administration of the War Office; (D) the relation of the Treasury to both Departments of State, and matters of financial control generally. We propose to make a few remarks, in the meantime, on the first two of those divisions. On the first of these it must be admitted that the arrangements have hitherto neither been reasonable nor business-like. The two Departments of the Army and Navy have, or ought to have, one duty and one combined work—viz., primarily the defence of the United Kingdom, its Colonies and dependencies, and the protection of its commerce, supplies of food, and other necessaries; and secondly, the organisation of the naval and military strength of the Empire with the view to the conduct of any hostile operations against foreign Powers in which the policy of the country may cause it to be engaged. What struck the Committee, and what must strike anyone who looks at the matter, is that, while in action, and even in the preparation for war, the two great fighting Departments must be largely dependent on each other, little or no attempt has ever been made to establish settled and regular inter-communication or relations between them, or to secure that the establishments of one Service should be determined with any reference to the requirements of the other, and that no combined plan of operations for the defence of the Empire in any given contingency has ever been worked out or decided upon by the two Departments. The naval authorities contend that it is essential to the efficiency of the fleet, and the success of naval operations, that absolute freedom of action shall be left to the naval commanders in time of war, and that this freedom of action would be impaired by any regulations or understanding involving the retention of certain ships at certain stations in order to aid in their military defence. On the other hand, the military authorities consider that it is essential to the completeness and efficiency of their preparations that they should be informed what amount of assistance they can definitely reckon upon from the Navy. The Committee mention several suggestions which have been made for bringing the Admiralty and the War Office into closer relation to each other. The first was that a Minister of Defence should be created, who would be the supreme and responsible head of both services, the immediate control of each service being entrusted to a professional officer. Another suggestion was that each Department should be entrusted to the supreme and responsible control of a professional head, the necessary link between the two services being provided by the appointment of a civilian Minister of high rank, whose principal duty would be to settle with the heads of each service the amount of annual expenditure required, to audit their accounts, and to form a channel of communication between them on all subjects of mutual importance. To both of those proposals the Committtee saw very grave objections, and they think that means might be devised for bringing about more regular and constant communications between the Admiralty and the War Office, and could be arranged by certain departmental changes, which might provide for very constant communication and consultation between two highly responsible naval and military officers on all questions where common action and preparation on the part of the two Departments are required. The Committee also suggest that there might be some advantage in the formation of a Naval and Military Council, which should probably be presided over by the Prime Minister, and consist of the Parliamentary heads of the two Services and their principal professional advisers, and they note that it would be essential to the usefulness of such a council and to the interests of the country that the proceedings and decisions should be duly recorded, as instances have occurred in which Cabinet decisions have been differently understood by the two Departments, and have become practically a dead letter.

The Committee do not propose any very sweeping internal changes. They recommend that the duties of the different members of the Board of Admiralty be more exactly defined and responsibility brought more directly home to them; and, in order that this may be done, they suggest that it would be an advantage if each

Digitized by Google

member of the Board were required to prepare annual reports of the condition and working of the branches of the Service placed unper his immediate control. These reports would form a useful foundation for the Memorandum which is now presented to Parliament with the annual Estimates by the First Lord, to the continuance of which in a complete form, as a record of past proceedings, the Committee attach considerable importance. They recommend that the First Naval Lord should be relieved from all duties except those for which he is specially qualified—such as, for instance, advising on the distribution of the fleet in time of peace or war; the relative strength of our own and foreign navies; the duties required of the Navy in the protection of our commerce and possessions; the number, class, and type of ships of war to be maintained or provided; the regulation with the War Department of all questions in which joint action or a definite understanding is required; and many other questions more than sufficient to occupy all his time. Further, in order to preserve the continuity which must at present be mainly maintained by the Civil officers of the Admiralty, the Committee are of opinion that the Naval Lords should be appointed for a definite period, subject to the right of the First Lord to select new Naval Lords when he considers a change desirable. The Committee state that Her Majesty's Navy is administered by civilians to a far greater extent than is the case with the navies of other Powers, and they recommend that the professional staff of the Admiralty be strengthened, and that naval officers be appointed to do some of the work now done by civilians. They think also that it would be an advantage if a naval officer were appointed as Permanent Secretary, provided that an officer can be found possessing the special qualifications for the post. The Committee's recommendations as to the administration of the Admiralty are summed up as follow:—1. Full recognition of the complete and individual responsibility to Parliament and the country of the Cabinet Minister at the head of the Department. 2. Constitution of the office of the First Naval Lord as that of Chief Adviser of the First Lord in all great questions of naval policy. 3. Clear definition of the administrative duties of each of the remaining Lords, and direct responsibility of each of them to the First Lord for his own duties. 4. The Board to be regarded as a Standing Council for Naval Affairs, but the existence of such council in no way to diminish the responsibility of the First Lord. There are several dissentients to some of the findings of the Committee.

LLOYD'S COMMITTEE ON SHIPBUILDING.

In a recent issue we referred to the advantage to be derived by Lloyd's Register from the proposed addition of technical members on the Committee. Our contention was that shipbuilding interests have not always been in accord with the laws emanating from that Society, and the system under which work was carried on, if a vessel were classed, as the majority are, in the Register. We expressed the opinion that the Committee would be considerably the gainers by giving outside scientific members some direction instead of relying wholly on the permanent staff, and that with such innovation it might be expected that many anomalies that had existed would be removed in the future arrangements of this body. Our remarks went even farther than this, and tended to show that virtually the paid servants of the Society were independent of any control whatever. They possessed the key of the whole situation by their professional knowledge, and were able to assume in consequence a sway that was not desirable.

Outside pressure was brought to bear, and the Committee eventually found it would be to the improvement of their own deliberations, as well as better for their officers, if extra-technical aid were introduced. They decided to reform themselves, in fact, and it is greatly to the credit of this old-established body that, the decision having once been taken, some vigour has been shown in carrying it into effect. Having advanced some distance on the road, however, it will come somewhat as a surprise that, in the forward movement set up at White Lion Court, serious revelations should have been brought to light respecting the engineering department. The charge is against Mr. Parker, and is that he has been pecuniarily influenced in his reports upon the fittings of ships. The result of the investigations of a sectional committee has been unfavourable to him, and suspension has followed. If there have been "considerations" paid by those who have benefited, it means that inferior articles have thus obtained undue notoriety, to the detriment of the mercantile marine generally. That shipping stands pre-eminent in England above that of any other country goes to prove in a great measure that no general action of this kind has been allowed to exist; but that there is a blemish at all connected with any of the Society's transactions is a serious matter, and shows that the resolution to admit professional men on the Committee was a very necessary one, and was adopted none too soon.

It is almost needless to say that the office which governs the constructive departments of all our shipbuilding yards wields an immense power. If, therefore, any section of it is not above suspicion, every report sent out partakes more or less of the same character. That the unhealthy spot has been discovered is satisfac- in so far as the public are partly assured that it is the only one. We may therefore presume that, under the new *régime* that has set in, greater strides than ever will be made. As we mentioned in our former remarks on the subject, success will be best attained by the Society confining itself to its own legitimate sphere of usefulness. It was established for certain purposes, and, with the vast proportions of the present shipping trade, it might reasonably be supposed that its surveyors always had their hands full in attending to the registration and classifying of ships.

THE FEDERATED INSTITUTION OF MINING ENGINEERS.

The second meeting of the Federated Institution of Mining Engineers was held in London, at the Institution of Civil Engineers, on Wednesday, the 30th ult. A paper on "Coal in Kent" was read by Mr. W. Topley, F.R.S., of H.M. Geological Survey. In this he briefly sketched the history of the question, showing that coal had frequently been found in the Wealden districts of Kent, Surrey, and Sussex. This coal was, however, a brown coal or lignite of the Wealden age, quite different from the carboniferous coal measures. He then passed in review the geological investigations as to the supposed underground range of the palæozoic rocks, with which coal measures are associated, from the North of France to the West of England, and described the various deep borings that have been made during the last thirty-five years in the South-east of England. All but two were in search of water. The two borings made especially for underground exploration were the Sub-Wealden boring (1874–77), and the search for coal at Dover, recently successfully completed. These bore holes have afforded valuable information as to the range and depth of the palæozoic rocks, proving that these rocks lie nearer to the surface than was expected, and that the overlying secondary rocks are thinner. The older rocks (Silurian) of the palæozoic series occur to the north of London at Ware, Devonian rocks further south; whilst red rocks of uncertain age have been found at Kentish Town, Crossness, Richmond, and Streatham. It was inferred that the coal measures would occur to the south of London, probably near the North Downs or under the northern part of the Wealden area. A comparison of the coalfields of the West of England with those of the North of France and Belgium indicates that in the south-east of England the coal would be found in detached basins, each separated from its neighbour on the east and west by older rocks. The coal, too, would be much disturbed and faulted, as is the case in the Bristol coalfield and in the North of France. In the latter district the development of the coalfields has been extraordinarily rapid, a result that is partly due to the fact that the French mining laws are very favourable to mining enterprise and to mineral researches. Now that public opinion is plainly directed to the subject, systematic exploration will doubtless be made in the south-east of England, and a great source of wealth for the district opened up. In conclusion, the author noted certain localities where explorations might well be carried out in the first instance—places where geologically low beds are brought to the surface being especially suitable. At Chatham Dockyard a boring is already 965ft. deep, and this could be carried much deeper at a comparatively small cost.

The discussion that followed the reading of Mr. Topley's paper was well sustained. A letter from Mr. G. C. Greenwell was read by the secretary, Professor Lebour, in which the probable state of things in the south-east of England was deduced from a comparison of the Somersetshire and North of France coalfields. Professor Hughes, of Cambridge, in his usual eloquent style, gave an exposition of the theory of faults. Mr. Bauerman, the Examiner in Mining to the Science and Art Department, contributed valuable details of the structure of the French coalfields, derived from information he had collected at the Paris Exhibition. Mr. Emerson Bainbridge thought that the results of the Chatham, the Sub-Wealden, and the Dover bore-holes indicated that further exploration would show that it was improbable that coal existed to any great extent. Mr. W. Whitaker, F.R.S., who had recently contributed a paper on the same subject to the Society of Arts, spoke at considerable length, and expressed very sanguine views. He urged the importance of continuing the Chatham bore-hole, and was of opinion that if coal is found in the south-east of England it will be at distinctly workable depths—say, 800ft. to 1,300ft. Water, if met with, would be a possible source of profit, and is not likely to occur in sufficient quantity to seriously interfere with the working.

At the conclusion of the meeting Mr. A. Smith, M.Inst.C.E., exhibited and described a patent adjustable automatic fire alarm and heat indicator brought out by a Birmingham company. The appliance is somewhat similar in construction to an aneroid barometer, and consists of sensitive diaphragms for electrically giving an alarm when the temperature of a building in which it is placed rises to that indicated by the adjustable index finger, which has a range of from 32° Fahr. to 200° Fahr. if required. It was thought that this instrument might be of considerable value to mining engineers, as affording an indication of increased heat due to imperfect ventilation. It might also be placed in the centre of coal heaps, so as to indicate overheating due to spontaneous combustion.

THE EDINBURGH EXHIBITION.

The Exhibition which was opened yesterday by T.R.H. the Duke and Duchess of Edinburgh is *the* Exhibition of the year. The indifference with which it was regarded when it was first proposed soon passed away, owing to the energy of the Executive and of Mr. Lee Bapty, and the result has been that a large number of important firms have taken an enthusiastic interest in the Exhibition, and made it a most successful show of electrical and other machinery.

On Wednesday evening the members of the press were entertained by the Executive to dinner, and were allowed a private view of the Exhibition. The exhibits individually will afford material for further detailed description; but it may be said that they represent as a whole the high-water mark of applied electrical science. It might go without saying that the halls and grounds are brilliantly lighted, arcs, sunbeams, and small incandescent lamps being used in profusion. The opening on Thursday was attended by the ceremonials usual on such occasions. After the formal proceedings were over the Royal party made a tour of the buildings and a general examination. In our issue of the 25th ult. we gave a general view of the Exhibition, and shall follow this up by detailed descriptions and illustrations of the most interesting of the exhibits.

Letters to the Editor.

THE BREAKDOWN OF THE "CITY OF PARIS."

To the Editor of "Industries."

Sir,—The particulars of the breakdown of the "City of Paris" naturally make engineers ask if the modern triumphs of shipyard construction are quite what they are supposed to be. Certain it is that but for the strength and subdivision of the hull, which saved the vessel in the emergency, the ship must certainly have foundered.

There can be no longer any doubt that the breaking of the propeller shaft was what happened first. In the anxiety to have the propeller as far aft as possible, to get solid water in which to turn, and at the same time to present as few obstacles as possible along the ship's run, it seems there was no support given to the shaft from the stern tube down to the boss held up by the usual brackets just forward of the propeller itself. This was for a length of between 50ft. and 60ft. At one end the shaft was 20in. diameter, and at the other 15in.; there would, therefore, probably be about 20 tons weight to carry outside the ship. This would be borne by the boss alluded to. The liners of this boss have worn down about 8in., proving what happened. Either, then, the original design of this detail must have been faulty in some particular, or, what is more probable, the bearing surface was not large enough for such a weight. However this may be, the shaft in dropping this depth broke off next to where it was held up forward, that is, outside the stern tube. Such a result was certain to follow from the first defect, as it is clear there would be a bending moment tending to fracture of over 500 foot-tons. That such an accident is novel may be accounted for in two ways. First, there are very few twin screw vessels built at all, and fewer still of this size and power. Conditions that apply to small types are of no avail when the dimensions become increased. Is it not just possible then that this is where the mistake has crept in? Instead of taking a big problem, like this undoubtedly is, as a new one, deductions were made from previous examples with the subsequent evil consequences. It is safe only to draw conclusions from what has gone before, when there is ample material to hand on which to work. There can be no doubt that a temporary blow has been struck against twin screws on ships, and the opponents of the system will be professionally jubilant for a time. It may be taken for granted, however, that boats under a certain tonnage are safe when built in this way. It is when the powers and weights are excessive, as in the large liners, that a new set of circumstances come into play

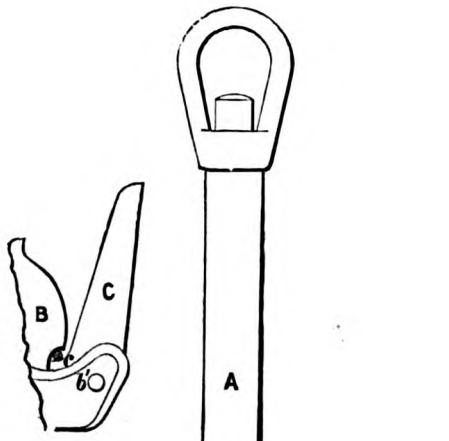

Fig. 2.

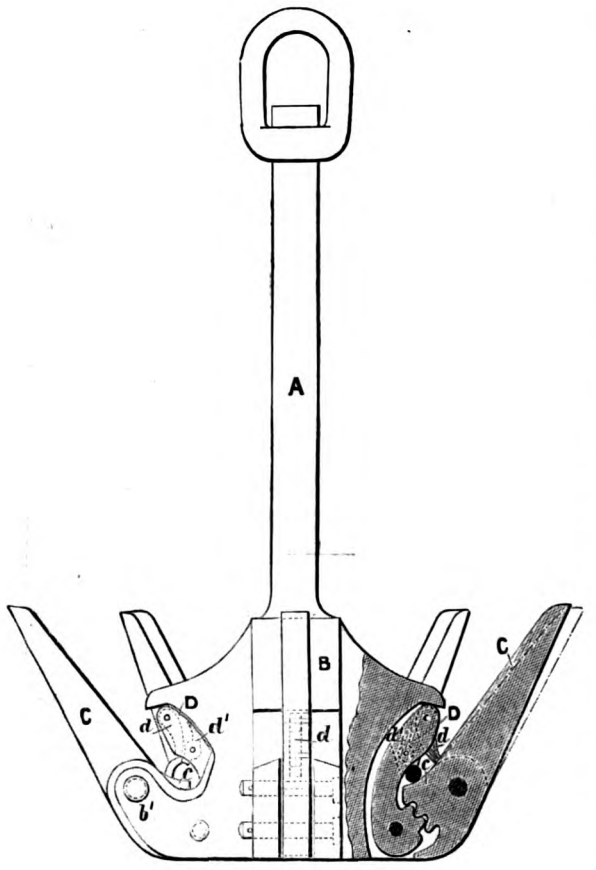

Fig. 3.

altogether, and it is not rash to predict that the design of the after parts in the shafts of these double-screw leviathans will be somewhat modified in future. Detailed suggestions would be out of place without drawings, but they will occur to every engineer.

When attention is paid to the engine-room, where the effects of the racing of the shaft, small though it may have been, were felt immediately, the peculiar feature is that only the low-pressure engine gave way. The high and intermediate engines remain intact. As all three engines drive the one shaft, the racing should affect them alike. The obvious difference is in the diameters of the cylinders, which are 45in., 74in., and 113in.—that is, 9½ft. for the largest. Now any sudden strain on the low-pressure piston requires to be specially provided for. As in the boiler one safety valve is not depended upon, so in a structure of these dimensions, even if a good governor be fitted to the engines, it is unwise to look to a small relief valve for full security. It is not known what the size of the valve in the present instance may be, but clearly it was inadequate for what was required of it. Probably it will be found that as the engine increased in area, if the valve did likewise, it was in an arithmetical rather than a geometrical ratio—in short, allowance was not made for any catastrophe such as the one that has occurred. It is a costly experiment to demonstrate that when we get to these very large engines dangerous ground is being trod upon, and that what are minor matters in a small engine become magnified to considerable importance under other conditions; but if a purpose has been served in this way, perhaps consolation may be derived from the fact that the engineers who were in charge of the machinery have withstood the ordeal and escaped with their lives.

Yours, &c.,

Marine Engineer.

London, 28th April, 1890.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

Sir,—We should have thought our letter in your issue of the 11th inst. was sufficiently plain to require no further explanation from us. The statement of your correspondent, "Car," was that our system required "a new roadway," which we denied. By "a new roadway" for a tram system we should imagine that anyone would understand the taking up and relaying of the rails in some different manner. Thus, the cable system requires a new roadway; so also do the electrical systems with underground cables, and the storage system also, in cases where the gauge is different.

On our system the existing roadway is in no way altered or interfered with, beyond the few feet occupied by the valve boxes at intervals of from a quarter of a mile to a mile or so apart, according to the gradients. We cannot understand how anyone could consider the laying of an air pipe, which seldom exceeds 4in. diameter, under the foothpath as "a new roadway." Even the laying of a gas or water main does not involve "a new roadway."

We have laid some hundreds of miles of air mains in the streets of towns in connection with the Shone drainage system, and we know "the distinction between pulling up the centre of a street and pulling up the sides" or footpaths, which your correspondent would soon find out if he had the work to do, especially if he had paved streets to deal with.

The Electric Traction Company's contract to run cars at 4½d. per mile has been persistently dinned into the ears of the public in a manner which would lead them to believe that that is the actual cost. The papers have lately been teeming with paragraphs about the great success of the electrical traction system, with the view of "educating" the public up to the point of subscribing largely for shares in electric traction companies. Those who are behind the scenes in regard to electric traction in America are aware that it cannot hold out much longer in that country; hence the strenuous efforts that are now being made to get up a "boom" in this country before the anticipated *exposé* in America, and to smother and hush up as much as possible the utter collapse of the electrical system in Brussels.

We have only to add that the conditions of working vary so greatly on different lines that it is altogether misleading to take the average cost of working several lines on our system, including one colonial line, and compare that with the charge on a London line which is merely contracted for by the Electric Traction Company.

The question is, Would it pay the Tramway Company in London to work its own electric traction any better than it did the Brussels Tramway Company, who worked their line long enough to learn something about the cost of maintenance and renewal of plant which the short trial on the Barking line was not sufficient to test?

Yours, &c.,

Hughes & Lancaster.

City Road, Chester, 24th April, 1890.

STEATITE AS A PIGMENT FOR ANTI-CORROSIVE PAINTS.

To the Editor of "Industries."

Sir,—In your issue of the 11th inst., which absence from England has prevented my seeing sooner, you reported some remarks made by me on the paper read by Mr. F. Goodall at the recent meeting of the Institution of Naval Architects on "Steatite as a Pigment for Anti-Corrosive Paint." The short notice in question, however, does not quite convey the real object of my remarks, and I should, therefore, feel extremely obliged if you would kindly grant me space to explain more clearly what I stated.

With regard to steatite itself, I merely pointed out that the Maritime and General Improvement Company, of which I am the chairman, has been employing it successfully in ships' coatings for about twelve years; but that it was found only to combine well with naphtha and not with oil. My reference to gas factories was in no way in relation to the above subject; I only incidentally called the attention of the members of the Institution to the extremely interesting sight then to be seen at the Mansion House Station, where the iron girders were being coated with a kind of cheap black varnish obtained from the gas factories and mixed with naphtha, the original coating of oxide paint mixed with boiled oil having proved an utter failure, as far as the preservation of the girders was concerned. Quoting from one of the addresses of Mr. J. Head, delivered as President of the Institution of Mechanical Engineers, I maintained that corrosion resulted solely from the oxygen contained in the oil—an opinion which is every day more and more confirmed by experience. The stations at the Temple, Charing Cross, &c., which were coated a long time back with the black varnish above referred to, present a striking contrast to those where oil paint is employed.

Yours, &c.,

Charles Fairholme.

30th April, 1890.

AN IMPROVED SUBMARINE GRAPNEL.

The disadvantage of an ordinary submarine grapnel is that it does not grip the cable or other body to be raised. The consequence is that the cable can easily slip off the flukes, especially if it is a loose end that is being raised. In order to remedy this defect, and to make the grapnel more sure in its operations, Mr. Henry Benest, of the India Rubber, Gutta Percha, and Telegraph Works, Silvertown, London, has devised the apparatus which we illustrate above. The essential feature of the invention is the conversion of the flukes into automatic gripping jaws.

In Fig. 2 we show a grapnel, in which one of the jaws is fixed and the other movable, Fig. 1 being a view of one of the flukes in the gripping position. The stem A of the grapnel carries at its lower end a boss B. The ribs *b* of the boss form inclined shoulders, which constitute the fixed gripping jaws. Below these ribs the boss extends laterally and forms five forks, which serve as supporting arms for the pivoted flukes C. These flukes form the pivoted gripping jaws; they take the shape of a bell-crank lever, their rear ends extending inwards beyond the centre of motion of the fluke, and, when depressed, causing the upper part of the fluke to advance towards the fixed gripping surfaces. The upper surface *c* of the tail end of the fluke is intended to receive the cable. As the cable slides over the flukes it will press upon the surface *c* of the tail end of the fluke, and by so pressing it will tip the fluke into the position of Fig. 1; by this means the cable will be automatically gripped between the fluke C and the boss B of the grapnel. On hauling in the grapnel the bite on the cable will be not only maintained but increased, and thus the tendency of the cable to slip, even though a loose end only is caught, will be removed.

In some cases, however, where the hauling in is irregular, the grapnel may drop suddenly and lose hold of the cable. To avoid this Mr. Benest has devised the form shown in Fig. 3. In this arrangement, instead of the fixed gripping surfaces forming part of the boss, there is a second movable jaw D, which, like the fluke C, is pivoted within the supporting arms b^1 extending horizontally from the boss B. The jaws D are connected with their flukes C by interlocking teeth, which ensure the simultaneous approach of the jaws C and D. Each jaw D is slotted longitudinally to receive a locking pawl *d* and a tumbler d^1. These pieces *d d* are pivotally connected to the jaw D, and the end of the pawl, when in its locking position, enters a nick in the gripping face of the fluke C. The tumbler is so formed that, when not in action, its lower end will project somewhat from the gripping face of the jaw D, as shown on the left hand side of Fig. 3. This is for the purpose of enabling the cable, as it slides in between the gripping surfaces, to tip the tumbler D^1, and thus bring the locking pawl *d* into position, as shown at the right hand side of Fig. 3. In order that the cable, whilst being hooked, may not be caught by and lodge upon the top of the jaw piece D, the boss is formed with a web which projects so as to cover the jaw piece. It will be seen that the cable when caught by the grapnel, and brought within the grip of the jaws C D, will be entirely prevented from escaping.

Reviews.

Electric Transmission of Energy. By Gisbert Kapp. Second Edition. London: Whittaker & Co. 1890.

Whatever Mr. Kapp writes cannot fail to be of value to the electrical industry, and considering the strides which have been made since the date of the first edition, he is to be congratulated that in revising this work for the present issue he has not found it necessary to eliminate as antiquated, from the descriptive portions, more than the account of the experiments of Marcel Deprez and one or two dynamos. On the other hand, it is to be regretted that more care has not been expended on the theoretical portions, which cannot be expected, in a book of this size, to form a complete introduction to the subject. Several pages might have been spared from those

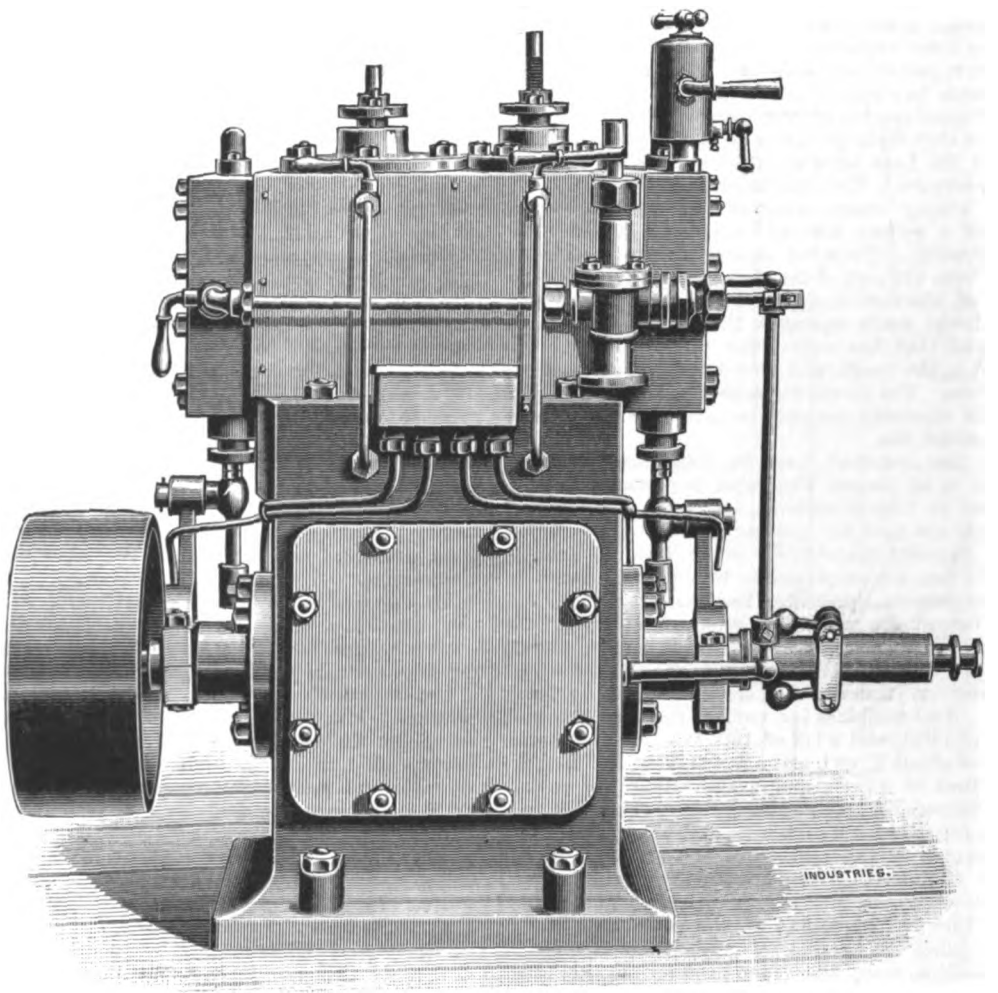
Digitized by Google

devoted to absolute measurements and to the theory of magnetism, in exchange for a few paragraphs on those quantities which are commonly designated by the symbols **B H I** and μ. On page 61 we find the somewhat loose statement, "Roughly speaking, we may take it that air offers to the lines of force about 800 times the resistance of iron," and this is not qualified by any remarks about the varying permeability, until after reading some forty pages, when it is only alluded to in the course of the discussion of magnetic resistance. There are a few mistakes of more practical importance, such as the statement that a compound dynamo will run at constant speed as a motor on a constant potential circuit if the series coils demagnetise. It would really run much too fast, unless Professor Ayrton is right in saying that the armature current strengthens the field in a motor.

The method of constant current regulation given on page 170 is particularly ingenious. Mr. Kapp still adheres to inch lines, and perhaps he is wise in doing so. He also goes with the times in using the idea of magnetic resistance. His magnetic resistance of 1,440 for air and copper must be wrong; it should be 1,880, or a trifle over, as copper is diamagnetic. If it were so magnetisable as that, a piece would stick strongly to a field pole. Some six pages of rather involved calculations are devoted to the discussion of the effect of a leak due to imperfect insulation on the efficiency of a dynamo and a motor, and it is suggested that the assumption generally made in text-books, that the insulation of the line is perfect, is to be discouraged. But a few pages later an example is worked out in which leaks are neglected. Bearing in mind that in such a case as the one cited, viz., two miles of copper wire, presumably on poles, 6·2 ohms, 14·5 amperes, 900 volts, the Board of Trade will not allow a leakage of more than one twenty-fifth of an ampere, 36 watts would be lost out of 22,500. A loss of 2,500 watts is put down to mechanical and magnetic friction of the dynamo.

Although we have dwelt somewhat fully on these faults, they detract but little from the value of this eminently useful and practical book, which can be recommended to all engineers who have to do with the subject, and to such students as can find time to read books other than those written to suit the syllabus of some examination.

HANDBOOK OF QUANTITATIVE ANALYSIS. By John Mills and Barker North. London: CHAPMAN & HALL. 1889.



We recently had occasion to praise the recent work of the same authors, entitled "Introductory Lessons in Quantitative Analysis," but from a perusal of this larger book we must conclude that Messrs. Mills and North would have done well in waiting before attempting any fresh publication. Such subjects as practical quantitative chemistry cannot be crammed by the student in the way the authors seem to imagine, and we should be very sorry to present ourselves for examination before the examiners of the Institute of Chemistry relying on the present volume as our only guide. The authors have added to their former book matter on the analysis of alloys, minerals and ores, commercial products, assaying of silver and gold, water, gas, and organic analysis in a very poor fashion, but obviously in order that the subjects mentioned in the Science and Art, University of London, and Institute of Chemistry respective schedules may be included in their book. We do not believe in books written on this plan, and feel confident that any student who relies on such teaching will not find his knowledge of much practical use to him in after life. The authors themselves apparently have only had experience of the first of these three examining bodies, and seem to forget that the conditions of success at the examinations of the other institutions are different.

COMPOUND HIGH-SPEED ENGINE.

WE illustrate above a high-speed compound engine recently constructed by Mr. A. W. Richardson, "The Electric Light and Engineering Works," Stretford Road, Manchester. This engine has been specially designed for dynamo driving, direct or otherwise, but it is equally suitable for any other purpose where great power in small space is required. It has been constructed to run at high speeds continuously with safety and economy, and without excessive wear. The cranks run in oil, and have wipers to prevent the oil from working out of the bearings. The wearing surfaces are very large, and are adjustable. No exhaust steam enters the crank box. These engines are made single or double acting, and when made double acting the piston glands have metallic packing. The cranks are effectively balanced, every part is fitted with efficient means of lubrication, and all parts are easy of access.

COMPOUND HIGH SPEED ENGINE.

CONSTRUCTED BY MR. A. W. RICHARDSON, ENGINEER, MANCHESTER.

THE GERMAN TESTING STATION AT CHARLOTTENBURG, NEAR BERLIN.

SOME articles have been written lately respecting the various fuel testing stations which have been established in Germany and elsewhere, and urging their adoption in England. With the penetration and scientific insight that distinguishes them, the Germans were among the first to perceive that the introduction of steam and machinery had revolutionised industry, and that it was, therefore, essential that the working conditions of a boiler, for instance, should be as perfect as possible. The relations between the steam and the combustible generating it having been determined, it has for many years been within the power of every coal consumer in Germany to have his fuel consumption tested at a small cost, and its heating value ascertained. And of late a fresh step has been taken. The Germans have succeeded in arranging for daily tests, on a large scale and by accurate scientific methods, on the strength and quality of iron, wood, steel, paper, oil, &c.—in short, of all materials used in machinery and construction.

About six years ago a testing station was established at Charlottenburg, under the auspices of the Prussian Government. The institution has been organised on a strictly scientific and commercial basis. A series of instruments have been devised, chiefly by the officials who conduct the tests, for carrying the trials out as perfectly as possible; and a fixed scale of charges has been drawn up. Any manufacturer, wishing to have a product of his mill or factory tested, is supplied with a tariff of prices, a list of the different methods by which the article specified can be tested, and precise instructions regarding the proper size of the samples to be sent in. Although the establishment is still in its infancy, it will be seen at a glance how important a place it may hereafter occupy in commercial industry. All disputed questions between buyer and seller as to strength or quality of goods delivered can be settled at once, and the interests of both equally protected by an appeal to the authorities at Charlottenburg. A still more critical function is there performed, by testing with scientific precision the strength of materials employed in bridges, buildings, &c.

The institution is under the superintendence of Herr Martens, a distinguished engineer. It is connected with the Technical and Mechanical High School at Charlottenburg, and has an engineering workshop attached to it, which forms an indispensable adjunct to the work undertaken, and a training school for the students. The substances tested are divided into four sections, viz.:—

I. Metals, wood, ropes, driving straps, chains, and al materials used in construction.
II. Lubricating oils.
III. Paper of all kinds.
IV. Gauging and testing machines.

I. As may be supposed, the work done in the first division is the most important. The usual method of determining the strength of metal is to test sample bars of a given size, but the actual parts of any structure can also be experimented upon. The station possesses the appliances necessary to determine the resistance to tension, pressure, percussion, bending, twisting, and buckling; also the tensile strength of leather straps and cords, sheet iron and corrugated plates. Wire is tested for its bending and twisting capacity, oil for its lubricating properties, and paper for strength and quality of material. Iron and other metals are also tested by weights falling vertically, and by an ingenious arrangement, to be described hereafter, these experiments can be carried out at a distance from the testing station. The tests applied are of two kinds:—1st, single experiments upon the tensile and ductile strength of the material; 2nd, repeated trials continued for a long time, and intended more especially to test for power of prolonged resistance. The metal bars generally used are from 1½in. in diameter and upwards. An ordinary simple test comprises: Determination of the limit of elasticity, breaking weight, the elongation of the metal, and diminution of area after fracture. Sleepers, girders, and iron columns are tested for resistance to sudden pressure, and the limits of elasticity obtained. Samples of iron for carriage and locomotive axles are tested, duly loaded and while revolving. The hardness of sheet iron and buckled plates, the strength of telegraph wires, and the tensile strength of wood, driving straps, steel, iron, and hempen ropes are also carefully proved and tested. To all these operations a regular tariff of prices is attached.

A complete trial of cast iron comprises the following processes:—(*a*) Three separate tests of the resistance

Digitized by Google

of the metal to bending. The size of the bars experimented on must be 3ft. 7in. × 1¼in. × 1¼in. (*b*) Tension and torsion tests, without determining the limit of elasticity, upon some of the bars already tested for bending. (*c*) Six pressure tests, made upon cubes 1¼in. side, cut from bars already tested.

In even the smallest experiments it is desirable to test not less than five bars of a certain prescribed size, as the average quality of the metal cannot be determined from fewer experiments. If special strength and solidity are required more elaborate trials are necessary. By these tests two important points are ascertained:—(1) The original quality of the materials used, and (2) the changes they undergo in the process of manufacture. The size of the bars experimented upon is a matter of much importance. The instruments for carrying out the tests are of course adapted for working upon material of a certain size, and are with difficulty adjusted differently. Tools for separating the portion to be tested from the rest of the metal are provided in the workshop of the station. It is so necessary that this portion should really represent the average quality of the material that the authorities prefer to have the metal sent in the rough, and to cut the test pieces from it themselves. The proper experiments for determining the limit of elasticity can only be carried out with bars of the standard size.

Testing the materials used in construction and in machinery is at present the most important function undertaken at Charlottenburg, and a large number of instruments are used for this purpose. Four machines, having a capacity respectively of 98 tons, 49 tons, 39 tons, and 1 ton, are employed to test the resistance of metals to tension, pressure, bending, breaking, &c. The two largest are worked by an automatic hydraulic accumulator, and are regulated by levers, screws, moving weights, and springs. Wire up to one-third of an inch in diameter is tested in a small machine specially designed. Two machines for vertical pressure, one with a weight of 110lb. and a fall of 14ft. 9in., the other with a weight of about 12 cwt. and a fall of 32ft., are used for sleepers, tires of wheels, and axles. Measuring instruments, a furnace for testing the elasticity of red-hot iron, crucibles for alloys and cast iron, and a forge complete the appliances in this section of the station. Eleven machines of different types are used for repeated and long protracted experiments. In each of them from four to eight bars can be tested at the same time, and in other machines the bending of loaded bars is repeated continuously so many times per minute. Ropes, cords, driving straps, and wood can also be tested in almost all these machines, and it is intended shortly to add appliances for percussion.

II. These, although the most important, are by no means the only experiments undertaken by the institution. Oil for lubricating machines is analysed and tested under ordinary working conditions. Nothing, perhaps, is more essential to the proper driving of machinery than to determine the quality of the materials used to prevent friction. The chemical laboratory, which forms one of the chief departments of the station, here becomes of value. The oil is subjected to twelve tests. The most important are the determination of the specific gravity and visible properties of the oil, as colour, transparency, iridescence, taste, and smell; its power of liquefaction at a temperature varying from 68° Fahr. to 302° Fahr.—for this the mean of ten experiments is taken. The coefficient of friction for a given speed and pressure is also ascertained, as well as the point at which the oil congeals and burns. The boiling point, the residuum after boiling, the quantity of acid contained, and the chemical analysis of the oil form part of the investigation. These experiments are easily and accurately carried out with various appliances, some of them automatic. Where a new vein of oil is struck, and it is desirable before working it to know the quality of the oil, the value of this systematic and scientific testing can scarcely be overrated.

III. Paper may be, and is, frequently subjected to the same exhaustive tests. All paper supplied to the Prussian Government must be tested and properly certificated before it is accepted; the value of other paper is ascertained at the wish of the buyer or seller. For these experiments the paper is divided into two sections, comprising (I.) strength of texture, and (II.) quality of material used. Each section is subdivided respectively into six and four classes, and every kind of official paper must pass a certain standard prescribed by Government. In Section I. the strength of the paper is tested according to a theoretical quantity called the "tearing weight." The weight required to break the paper is first ascertained, and then reckoned in so many thousand feet of paper of the same width. Thus the tearing weight of a first-class paper will generally be about 5,466 yards of paper. The paper is also tested for its elasticity, resistance to creasing and crumpling, material of which it is composed, and especially for any admixture of mechanical wood-pulp, which is rigidly excluded from the composition of all good paper. The tests usually applied to a paper are: Determination of its tearing weight and elasticity, of its resistance to friction and crumpling, quantity of ash left after combustion, chemical examination to detect wood-pulp if present, microscopical examination of the fibres and other materials in the paper, and chemical analysis of the colouring matter, acids, chloride, &c., in the paper and sizing. The shape and quantity of paper to be sent in is fixed by the authorities, though it is not so strongly insisted on as in the case of metals.

IV. A fourth branch of the institution, which has not yet assumed large proportions, is that of testing the instruments and appliances used to prove the strength of metal. These machines are either completely tested in all their parts, or the accuracy of certain important sections, as weights, scales of measurement, levers, &c., are carefully verified. Attached to this branch of the establishment is a department for enabling manufacturers to make practical use of those methods of testing which have here been reduced to a science. Small copper cylinders 2in. in height and ¾in. in diameter are sent, if desired, with a copy of the testing certificate. The cylinders are subjected to the same heavy vertically-falling weight as the metal to be tested. Their power of resistance to pressure being accurately known, the effect produced on them is calculated, and the resisting strength of the iron deduced from it. This forms a simple and convenient method of testing iron. It obviates the difficulty and expense of conveying heavy blocks of metal to the testing station, while at the same time it ensures the same scientific accuracy as in the experiments there undertaken.

Another useful branch of the institution is devoted to photography. Views are taken of exploded boilers, broken bridges, and other iron structures, and of large pieces of wrecked machinery, and afford a valuable record of the condition of the iron at the actual moment of fracture. Many of these interesting photographs were shown at the section allotted to the Charlottenburg Testing Station in the Berlin Exhibition of 1889. A valuable and instructive collection of objects was also exhibited, comprising fragments of iron from exploded boilers, the exact point in a girder where it had given way, the piece of defective metal which had caused the collapse of a building, together with models or photographs of the various apparatus and appliances used in the testing operations of the station.

YEADON & ADGIE'S GAS RETORTS.

From the earliest days of gas manufacture the great desideratum has been a mechanical method of charging and discharging the retorts. In the first place, the employment of a machine would reduce the amount of wages paid to hand labour, and would place the industry beyond the influence of strikes. Again, no time would be lost between the charges, nor could any gas escape while the retort was being filled and emptied. Further, the operation of distillation would be conducted more rapidly, for each particle of coal would stay for a shorter time within the retort, and during the whole time it was there it would be subjected to the heat of the furnace instead of lying stationary for a certain period buried among its neighbours. It has been known for some time that the greater the rapidity with which the distillation is effected the greater is the quantity and illuminating power of the gas given off. Until recently, perhaps, Brunton's and Scott's retorts were the only successful embodiments of these principles, but of late years many forms of apparatus have been introduced with greater or less success.

A new machine is now being introduced by Messrs. Yeadon & Co., engineers, Leeds, which promises to leave all its predecessors behind, for, in addition to its possessing all the usual advantages of a mechanically charged retort, there are a number of remarkable points in its design. Their retort differs from all previous ones by being arranged to revolve instead of being fixed, and by being able to deal with the very smallest coal, even breeze. We will now proceed to give a description of the plant, but before doing so we may remark that several leading gas companies in England have already recognised its advantages, and have decided to adopt it at their works.

In the illustrations on the opposite page, Fig. 1 is an elevation of the feeding end of the retort, Fig. 2 is a side elevation, Fig. 3 is an elevation of the discharging end, and Fig. 4 is a longitudinal section through the centre. The body of the retort A is made of fireclay, and of cylindrical conical shape; it revolves inside the furnace B, and rests at each end in the metal sockets C C^1, to which it is secured by bolts. These sockets are made to revolve smoothly on bearing rollers D D, which revolve in the metal boxes E E^1. The retorts are suspended, with no brickwork underneath them, and thus, in revolving, the heat of the furnace comes in direct contact with the whole of the fireclay body. The interior of the retort has a number of continuous blades Y Y, extending nearly the whole length. The object of these blades is threefold—viz. (1) to work the coal through the retort; (2) to raise the coal constantly from the bottom of the retort to a point nearer the top, and then to allow it to fall over; and (3) to strengthen the shell of the retort so as to make it better able to carry the weight of the coal. These blades are made of a tapering form, deepest at the front or feeding end, where the coal requires to be broken up most, and gradually tapering to nothing about the point, thus preventing the coke from being unnecessarily broken after the gases have been liberated. The retorts are conical and widest at the discharging end. At each end there is a fixed end-plate in a recess, in which the ends of the retort revolve. A steam chamber at the back of these recesses keeps the necessary packing rings up to the retort ends, and makes a gas-tight joint. The front end-plate F has a hopper G, into which the coal is fed from the conveyer V (Figs. 1 and 2) after being delivered there by the elevators W. At the bottom of the hopper G there is a cylinder H, of smaller diameter than the retort, and this cylinder is fitted with internal shaft I, on which adjustable blades are fixed. The speed of this internal shaft is regulated by the change chain wheels K and K^1. As the cylinder is always kept full of coal, any escape of gas or ingress of air is prevented. The cylinder delivers the coal into the interior of the retort. On arriving here it falls on the bottom, and is caught by the blades, which operate on the coal as described before. The annular ring in the interior of the retort prevents the coal from working back into the recess L. This constant turning over of the coal promotes rapid distillation. The back end-plate S, like the front one, is fitted with grooved recess, packing rings, and steam chamber. A scraper X guides the coke into the discharging outlet pipe U, which is fitted with two discharging valves. By means of these valves and a swing door, the hot coke can be delivered right into the furnace B, or into a water cistern, or into an endless conveyer. The retorts are driven at each end by spur wheels M M^1, fixed on the metal sockets. This arrangement avoids any torsional strain on the body of the retort. These wheels receive their motion from the pinions N N^1 on the shaft O, which again is connected by the bevel wheels P P^1 to the main driving shaft R. The gases which are the result of the distillation escape up the ascension pipe T, which is purposely arranged at the hottest end of the retort, in order to prevent choking.

THE QUALITY OF ROOFING SLATES.

H. Brunner, in a communication to the *Schweizerische Wochenschrift für Pharmacie*, has recently showed how useful information on the quality of tiles can be obtained from their physical and chemical properties. In the first place, he points out that the colour of a roofing tile does not afford any safe indication of its durability, but that uniformity in the direction of the surface markings, which should be parallel to the length, is a desirable quality. A good slate should also be hard and not easily indented with the nail. He finds that the hardness varies between 2 and 3·5 in slates from various localities. The mechanical properties, such as its freedom from splitting into thin plates on sawing or hitting, should also be first noticed. The determination of the specific weight gives no useful information. Good slates give a clear ring when struck, while inferior qualities have a dull sound. From a microscopical examination of a thin section it is easy to recognise the presence of calcium carbonate, iron pyrites, and marcasite in the slate. A large amount of any of these is deleterious, and especially the last, as, from the readiness with which it undergoes oxidation, slates containing this sulphide of iron soon become friable and worthless. The porosity of slates can be readily determined by imbibition of water. A piece 12cm. long and 6cm. wide being stood in a beaker which is filled with water to the depth of 1cm., the beaker is then closed with a glass plate, and after standing for twenty-four hours the height to which the water has ascended in the slate above the water level is noted. Good qualities allow the water to rise only a few millimetres, while porous slates and those liable to split give a much greater height. The chemical analysis is of great importance, as it supplements the microscopical examination and gives the percentage amount of calcium and magnesium carbonates and iron sulphides present, all of which have an important influence on the weathering properties of the slate.

Fresenius many years ago pointed out that the presence of iron pyrites and other sulphides in slates influence their quality, and described in his *Zeitschrift*

für Analytische Chemie (VII.,72) the experimental results obtained by a chemical examination of several different kinds, and which are fully supported by this investigation of Brunner. The behaviour of slates towards sudden changes of temperature has also been the subject of direct experimental examination, Brunner suggesting that the quality in this respect may be estimated by first saturating the slate in water by allowing it to remain immersed in water for some days, and then placing it in a mixture of salt and ice for 24 hours. Its behaviour on heating can also be ascertained by warming a sample to 250°–300° C. for five to six hours, and then suddenly plunging it into water. A rough approximation of the quality of a slate may be obtained by immersing the broken fragments in hydrochloric acid, when a bad quality material will at once be recognised by the amount of carbonic acid gas evolved from the limestone present. By heating some chips in a glass tube closed at one end, a sublimate of yellow sulphur and a smell of sulphurous acid will be observed in most inferior kinds of roofing slates.

Notes.

MIXED FUEL FOR STEAMERS.

Some experiments have recently been made at Spezzia on the Italian man-of-war "Messaggiero," with a view to ascertaining the speed attainable with coal and petroleum mixed for fuel, and they seem to have resulted in producing a high speed at a given moment. The "Messaggiero," which never before surpassed fifteen knots an hour, reached almost seventeen with the new process of combustion, so that the increased speed supplies a very valuable assistance to a ship imperfectly defended. It is stated, however, that the immense heat generated affects the boilers injuriously, but arrangements are being made for obviating this in the future.

PROPOSED CANAL IN RUSSIA.

The latest proposal which we have heard for a canal is one for connecting Lake Onega and the White Sea, for which we understand all the preliminary arrangements have been made and laid before the Minister of Public Works. The advantage of connecting the White Sea with St. Petersburg and the centre of the Empire by means of a waterway has long been recognised both by the Government and in commercial circles. A port is to be constructed on the White Sea, and, according to present proposals, the canal will be 145 miles long, of which, however, only about one-half will have to be artificially constructed, and it will be wide enough and deep enough to admit vessels drawing 10ft. of water. It is expected that when the scheme has been carried out it will greatly help to develop Russian trade.

SEA FISHERIES OF THE UNITED KINGDOM.

According to the annual report of the Board of Trade on the sea fisheries, which has just been issued, the quantity of fish landed on the coast of England and Wales in 1889, exclusive of shellfish, amounted to 6,465,000 cwt. The value was £3,862,000, which, with the addition of £307,000 for the shellfish, gave a total value of £4,169,000. These figures have been about practically the same for several years past. The corresponding figures for Scotland show a total quantity of 5,416,000 cwt., exclusive of shellfish, valued at £1,431,000, while the total value, including shellfish, was £1,494,000. The aggregate result for the United Kingdom was a total of 12,678,000 cwt., exclusive of shellfish, valued at £5,608,000. Adding to this the value of the shellfish, amounting to £386,000, there was a grand total of £5,994,000 as the return of the sea fisheries of the United Kingdom, as valued at the place of landing, in the year 1889.

WEST OF SCOTLAND ENGINE KEEPERS' ASSOCIATION.

When we hear of proposals for the Government examination of engine attendants it is satisfactory to find a voluntary association which, for the district in which it is situated, appears to be doing very good work. The West of Scotland Engine Keepers' Association recently held its third annual meeting in Glasgow, at which the secretary was able to report very satisfactory progress. He stated that the object of the association was not to advocate legislative interference in the management of engines and boilers, nor for sinister purposes against steam users, but to cheerfully lend their best assistance to the development of sound instruction in the management of engines and boilers, enabling them to look forward with greater certainty to a considerable diminution, if not a prevention, of those calamitous explosions which so frequently plunge whole families into mourning by unexpected and instantaneous death. The association, which was formed three years ago, has now a roll of two hundred members, all of whom have passed the Board of Examiners. This Board is composed of professional engineers, who assign first and second class certificates on proof of testimonials of good character and a knowledge of elementary principles. It is further satisfactory to find that numbers of important steam users are recognising the aims of the association, and have shown a desire to employ its members in preference to others, as it was found that their good conduct and superior knowledge entitled them to confidence, and were at once a guarantee of public safety and of prosperity to the public.

HARBOUR WORKS AT YOKOHAMA.

Ever since foreign intercourse has been carried on with Japan, one of the greatest wants has been found to be proper harbour accommodation at Yokohama. The Bay of Yedo (Tokio) covers a large area, but it is so shallow that all ocean-going steamers have to discharge their cargo at Yokohama and send it by rail to Tokio. The harbour at Yokohama is unprotected, and has no appliances for the shipping and discharge of cargo, and everything has to be done by small boats, a system which is both troublesome and expensive. Very many schemes have been from time to time proposed, but it is only recently that definite plans have been made out and agreed to, and at present there is a representative of the Japanese Government in this country engaged in making contracts for the materials to be used in the construction. The works will include two breakwaters nearly two miles in length, together with beacons, dredgers, and all other requirements of first-class harbour works.

FRENCH RAILWAYS IN AFRICA.

We recently mentioned the French proposals for a Trans-Sahara Railway. This is only a small part of what is being done to promote French interests in Africa. A French company is now being formed for the purpose of constructing a railway from the coast to the Congo, and thus developing that region; and as the sanction of the Government has been obtained, the work will be actively pushed on. In Tunis considerable speculative activity is being shown, and a bank under French auspices has been formed for the purpose of assisting industrial enterprises, and railways have already been extended in several directions. Several French travellers have penetrated into various parts of Africa, and have strengthened old stations or established new ones for the purpose of extending French commerce. The effect of these various efforts has been to bring a considerable amount of trade and commerce to France.

THE CULTIVATION OF PISTACHIO NUTS AT ALEPPO.

The last *Kew Bulletin* contains a report from the Consul at Aleppo on the method of cultivating the pistachio tree prevailing there. It is produced only from the seed, which is steeped in water for two days and then planted in the nurseries and watered at least twice a week for two years, when it is grafted from a good fruit-producing tree. After another year it is transplanted to the pistachio gardens, where it is again watered for a year, or until the roots are well fixed. It is then left to nature, no more water being given. The gardens are ploughed up twice a year—in spring and winter—and the spade is used round each tree as with the olive. The tree does not naturally reproduce itself, although when the ground is exceptionally moist the seed sometimes, though rarely, fructifies itself. Two years after being grafted it begins to produce fruit. The distinction between the male and female trees is not understood, but those producing fruit of good quality are supposed to be female. It is not until the tree is seven years of age that it begins to give a good crop. Like the olive, the pistachio has alternate years of good and bad crops, and ordinarily good trees bear for sixty to eighty years. Excessive frost sometimes dries up the trees, and then they are cut down and uprooted, as shoots never appear. The tree is 12ft. to 15ft. high, and thrives best in a whitish chalky soil which retains moisture. In this and many other respects it resembles the olive.

TRAFFIC OF THE SUEZ CANAL.

In a recent issue (*Industries*, 14th March, 1890) we published a table showing the traffic through the Suez Canal during the past three years. The following table, which has been prepared by Messrs. F. W. Allen & Co., Buchanan Street, Glasgow, shows the percentage of steamers and tonnage belonging to the six leading maritime nations, and from which it will be seen that that belonging to Britain tends to increase:—

	1887.		1888.		1889.	
	Stmrs.	T'nage.	Stmrs.	T'nage.	Stmrs.	T'nage.
British	74·28%	76·52%	76·31%	78·65%	76·23%	78·91%
French	5·90	6·51	5·44	5·83	4·91	5·33
German	5·07	3·72	4·74	3·58	5·66	4·27
Netherland	3·92	3·75	3·52	3·28	4·26	3·87
Italian	4·40	4·28	4·24	4·03	3·01	2·76
Austro-Hungarian	2·61	2·39	1·69	1·85	1·58	1·72

BASIC SLAG AS AN ARTIFICIAL MANURE.

We have several times pointed out the importance of basic slag as an artificial manure, and have suggested that more attention should be paid to its qualities in this country, where they do not seem to be so highly appreciated as on the Continent. From the annual reports of the Sussex Association for the Improvement of Agriculture, and the Agricultural Research Association, we gather most emphatic support of the value of basic slag as an artificial manure. The experiments show that the phosphate in basic slag is clearly of a nature that can be assimilated by the plant, and that the power of the plant to make use of insoluble mineral phosphate is not, therefore, limited to the forms of it found in nature, termed coprolite, but extends to this artificial or manufactured form, and further that the prejudicial effect which was apprehended from the action of iron in basic slag has not been experienced. These conclusions are very satisfactory, and show that a very important bye-manufacture can always be connected with that of basic steel.

THE EMERY MINES OF GREECE.

The French Consul at Syra, in a recent report on the emery mines of Naxos, supplies some interesting information about the emery which is found in Greece. Naxos emery is universally known, and has a high reputation; it is the hardest and finest in the world. The ferruginous elements which it contains are so covered that the magnet exerts no appreciable action on it. Its composition is 80 parts aluminium, 3 parts silica, 4 iron, and 1 part not separated. According to the classification adopted by savants and, among others, by Mr. Tennant, the plain and red Naxos emery, which contains neither gold nor silver, comes from copper mines. It is therefore superior to that met with in iron mines, and which is of a blackish colour. By reason of its exceptional qualities it answers best to the needs of the arts and industries. In England and America it is used to polish gold, to cut and polish glass, marble, and the hardest stones. In some countries even it is combined with gold to increase the hardness of that metal. The consumption of this emery, both in America and Europe, is estimated to be nearly 20,000 tons.

THE SILK TRADE OF JAPAN.

The silk industry of Japan promises to become the most important in the country. We learn from a recent issue of the *Japan Weekly Mail* that new plantations are being laid out, new filatures and re-reeling establishments being started, new firms and companies beginning business, and constant improvements being made which are making the Japanese product more popular with manufacturers in Europe and America. Not only is the exportation of the raw silk being largely increased, but the goods woven in the Japanese looms are finding their way to Europe and America, where the beautiful fabrics of artistic Japan are greatly appreciated. In 1889 the value of the raw silk exported was $26,332,900, as against $25,899,700 in 1888. The export of waste silk was valued at $2,509,500, against $2,794,700 in 1888. The trade in manufactured silks grows year by year. Large factories, with new and improved machinery for warping, winding, weaving, and dyeing are being constantly erected, and the industry is fast developing. The United States is at present the best customer for these goods, but England, France, Germany, Canada, and Australia are rapidly entering the field as competitors in the purchase of these fabrics. At the present rate of progress the value of woven silks will soon exceed the value of tea annually shipped from Japan.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

14th April, 1890.

5603. Proctor, J. ..... Mechanical stokers.
5606. Marsden, H. M. ..... Manufacture of nails.
5607. Weight, W. H. ..... Machine for heeling boots.
5616. Fraser, W. ..... Furnace bars.
5618. Wishart, T. G. ..... Governor for steam engines.
5625. Sutcliffe, J. ..... Looms.
5627. Rome, J. C. ..... Metallic flooring for bridges.
5633. Stratton, J. M. ..... Steam generators.
5641. Howard, H. (of the Firm of Lloyd & Lloyd) ... Iron and steel tubes.
5643. Newton, H. E. ..... Rotary engine (*Jones & Green*).
5648. Bessonoff, S. ..... Regulating supply of feed water.

15th April, 1890.

5654. Allison, H. J. ..... Heating apparatus (*Edgar*).
5658. Wattie, W. ..... Turning and drilling machines.
5659. Marble & Simons ..... Forging metals.
5661. Rogers & Paramor ..... Revolving boilers.
5663. McKenzie & McKenzie Self-detaching gear for boats.
5665. Malmstrom, K. K. ..... Quick-firing guns.
5669. Palmer, J. H. ..... Car starter.
5675. Brearley, A. ..... Mules.
5676. Van Fleet & Graff ... Typewriter.
5680. Weber & Mayer ..... Wood screw machines.
5684. Henderson, C. ..... Sheet metal boats.
5685. Kidman, J. ..... Furnace doors.
5690. Beetlestone, R. ..... Doors of lift wells.
5692. Smallman, J. W. ..... Revolvers.
5697. Seabury, S. ..... Breechloading cannon.
5698. Newton, H. E. ..... Sewing machines (*National Machine Company*).
5702. Hansen, G. E. ..... Boiler tubes.
5704. Butman, T. R. ..... Flue scraping rods.
5706. Hall, Whittaker, & Fallows ..... Jacquard apparatus cards.
5709. Longmore & Watson ... Spinning machines.
5710. Löfström, L. ..... Typewriting machines.
5711-2. Longmore & Watson Spinning machines.
5713. Brickley, W. H. ..... Sewing machines.
5714. Mewburn, J. C. ..... Looms (*Campion*).
5717. Godfrey, A. ..... Boring tools.
5720. Kneen, W. ..... Utilisation of pressure for the obtainment of motive power.
5724. Lake, H. H. ..... Locking nuts (*Knapp*).
5725. Bowen, J. H. ..... Mechanical movements.
5729. Weiss, F. J. ..... Governors for steam engines.
5731. Imray, O. ..... Coupling metallic pipes (*Hogan Engineering Company*).
5732. Imray, O. ..... Partitioned pipe (*Hogan Engineering Company*).
5733. Imray, O. ..... Promoting circulation in boilers (*Hogan Engineering Company*).
5734. Imray, O. ..... Boiler furnaces (*Hogan Engineering Company*).

16th April, 1890.

5739. Cresswell, C. ..... Sewing machines.
5741. Chadburn & Findlay ... Ships' boats.
5743. Starkey, T. ..... Machinery for bending hay forks.
5749. Whalley, C. ..... Looms.
5755. Heath, G. ..... Firearms.
5766. Ellams, G. ..... Steam boilers (*Ellams*).
5774. Mellor & Mellor ..... Knitting machines.
5778-9. Roberts, G. C. ..... Reversal gears.
5784. Marley, H. ..... Winding machinery for textile materials.
5785. Lake, H. H. ..... Apparatus for heating and cooling fluids (*Joennson & Berg*).
5786. O'Donnell, F. H. ..... Lifeboats.
5787. Dunbar, A. ..... Machinery for manufacture of casks.
5789. Mayor, P. H. ..... Cylinders and pistons. (21st October, 1889.)
5795. Cooke, E. W. ..... Roller bearings.
5799. Reid, J. ..... Governor for steam engines.
5801. Corrigall, W. E. ..... Mounting ordnance.

17th April, 1890.

5808. Pritchard, Snape, & Sherratt ..... Lubrication of axles.
5811. Simpson, J. ..... Pipe-welding apparatus. (18th October, 1889.)
5813. Mynsbrugge & Mynsbrugge ..... Typewriting machines.
5814. McGrady, H. ..... Typewriters (*Crandall*).
5826. Aylmer, P. ..... Hoists.
5828. Womack, C. ..... Machines for extracting carbonised burr from woollen cloth.
5829. Ewen & Mitton, Jun. ... Machines for drying sand.
5834. Smith, J. R. ..... Pipe wrenches.
5840. Strathern, A. G. ..... Reversing and steam brake engines.
5844. Leachman, W. B. ..... Boiler furnaces.
5848. Wardle, W. W. ..... Apparatus for moistening air.
5851. Reid, J. ..... Self-lubricating valve spindle.
5853. Beechey, C. G. ..... Gas governors.
5854. Capel & Ladd ..... Apparatus for weighing and baling peat.
5855. Osenbrück, J. A. ..... Utilising exhaust steam.
5857. Boyle, R. K. ..... Utilising the force of railway trains whilst stopping.
5865. Hutchens, W. ..... Mitreing machine.

18th April, 1890.

5869. Wright, G. ..... Looms.
5872. Dale & Dale ..... Heel-paring machines.
5877. Duncan & Latta ..... Apparatus for making corks.
5878. Wild, J. ..... Valve gear.
5879. Riley, J. H. ..... Machinery for folding fabrics.
5881. Marsden, H. M. ..... Circular saws.
5887. Golding, W. ..... Spinning machinery.
5891. Kerr, J. ..... Evaporating salt water.
5894. Boult, A. J. ..... Converters (*Bookwalter*).
5897. Brown, A. G. ..... Steam generators.
5899. Robinson, T. N. ..... Wood planing and moulding machines.
5904. Lange, O. ..... Signalling on railways.
5908. Turnbull, Stockdale, & Carr ..... Calico printing machines.
5915. Bonne, C. R. ..... Preventing loss of water in water-pipes in case of bursting (*Herrnberg & Zipperling*).
5917. Mackie, S. A. ..... Washing machines.
5918. Ellis, E. ..... Boats.
5921. Thomas, H. M. ..... Sheep shearing machines (*Blanks, Lefebure, & Bird*).
5922. Oriolle, P., Fils ..... Steam boilers.
5926. Pitt, S. ..... Machine for covering electrical conductors with lead (*Atherton*).
5929. Carbonnier & Molié ... Spinning machines.
5930. Perry, F. J. ..... Embroidery machines.
5933. Dheyne, De Nydprück, & De la Hault ..... Gas engines.
5934. Nisbet, W. R. ..... Detaching ships' boats.

19th April, 1890.

5941. Adnams, F. J. ..... Raising sunken vessels.
5942. Holden, H. C. L. ..... Firing ordnance.
5943. Moore, A. S. ..... Casting cylindrical vessels.
5949. Leverkus, K. ..... Horse-power gauges.
5950. Freeman, J. G. ..... Grinding machine.
5952. Darroch, J. ..... Condensing engines.
5962. Maynard, R. ..... Elevators.
5963. Thomson, W. ..... Axles.
5966. Pullman & Smith ..... Machinery for finishing skins.
5969. Baldwin, B. J., Jun. ... Bending sheet metal. (18th November, 1889.)
5972. Otto, N. A. ..... Gas engines.
5985. Edwards, B. J. ..... Speed regulating pulley.

ELECTRICITY.

14th April, 1890.

5640. Watson, C. ..... Electric safety fuses.
5645. Odell, J. B. ..... Electric railway apparatus.

15th April, 1890.

5678. Kalb, J. ..... Electric regulators.
5716. Manville & Madgen ... Producing currents.
5728. Lake, H. H. ..... Regulating dynamos (*Foote*).

16th April, 1890.

5748. Jamieson, A. ..... Galvanometers.
5750. Crompton, R. E. B. ..... Dynamos and motors (*Fritsche*).
5764. Thompson, W. P. ..... Electrical inter-communication (*Berne & Taylor*).

17th April, 1890.

5804. Pollak, C. ..... Electric miners' safety lamps.
5810. Rawson, F. L. ..... Galvanic battery (*Hartmann & Braun*).
5836. Radcliffe, J. ..... Regulating dynamos and motors.

18th April, 1890.

5910. Jarman, A. J. ..... Insulating conductors.
5916. Bonne, C. R. ..... Electric alarm (*Mix & Genest*).
5920. Schoop, P. ..... Accumulators.
5925. Kellogg, M. G. ..... Telephony.
5938. Boettcher, K. E. ..... Secondary element.

CHEMISTRY.

14th April, 1890.

5608. Letcher, J. ..... Recovering tin from slag.
5620. Bowden & Hern ..... Soap.
5638. Teague, T. ..... Extraction of tin from slag.

15th April, 1890.

5721. Hall, J. ..... Colouring matters.
5722. Willcox, B. ..... Diquinoline derivatives (*Farbenfabriken vormals Friedrich Bayer & Co.*).
5723. Willcox, B. ..... Phenacetine derivatives (*Farbenfabriken vormals Friedrich Bayer & Co.*).
5736. Imray, J. ..... Colouring matters from azoxyamines (*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, Poirrier, & Rosenstiehl*).
5737. Imray, J. ..... Colouring matters from fluoresceine (*La Société Anonymes des Matières Colorantes et Produits Chimiques de St. Denis*).

16th April, 1890.

5777. Imray, O. ..... Colouring matters (*Farbwerke vormals Meister, Lucius & Brüning*).
5780. Imray, O. ..... Colouring matters (*Farbwerke vormals Meister, Lucius & Brüning*).

18th April, 1890.

5937. Loe, W. C. ..... Recovery of metals.

19th April, 1890.

5971. Dewar & Redwood ..... Distillation of oils.

MISCELLANEOUS.

14th April, 1890.

5605. Livesey, J. F. ..... Shuttles.

15th April, 1890.

5719. Taylor, W. R. ..... Manufacture of cement.
5730. Lake, H. H. ..... Insulating compound (*Knudson*).

16th April, 1890.

5762. Rocke & Prosser ..... Shuttles.
5775. Veasey & Brough ..... Packing for stuffing boxes.
5776. Gottschalk, R. ..... Fire escape.
5790. Patton, H. B. ..... Fire escape.
5793-4. Puskas & Schlenker Submarine blasting.

17th April, 1890.

5815. Raudnitz, S. ..... Substitute for glass.
5816. Hall & Kay ..... Sliver cans.
5823. Perry, J. ..... Signalling.
5827. Rigby, A. B. ..... Concrete blocks.
5833. Tall, G. ..... Refining cotton oil.
5838. Pielsticker, C. M. ..... Mineral oils.
5847. Wood, C. ..... Manufacturer of fibrous material from slag.

18th April, 1890.

5886. Thompson & Thompson Shuttles.
5898. Howat, A. ..... Miners' safety lamps.
5927. Lloyd, E. W. ..... Sights for ordnance.

19th April, 1890.

5948. Moffitt, G. ..... Time fuse for shells.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Milling Machines.—*G. Collett, Ashton-under-Lyne, and J. Hollingworth, Dobcross, Yorkshire.*—In the usual form of this class of machine tool the cutter spindle is carried at one end by a headstock, and at the other by a fixed radial arm cast to the headstock. To obviate the impediment of the radial arm in cutting certain forms and shapes of work, the inventors make the arm so that it can be revolved or oscillated, and its position altered to suit the work. The radial arm and headstock are cast separately, and the headstock has a flange with an annular groove formed in it. A flange corresponding to that on the headstock is formed on the radial arm, and T-headed bolts, sliding the groove of the former, pass through holes in the latter, and so provide the means of clamping the arm in any position. Claims: In milling machines for cutting metals the use of an adjustable radial arm such as that herein described and shown for the purpose set forth.—No. 7236. May 1st, 1889. 6*d*.

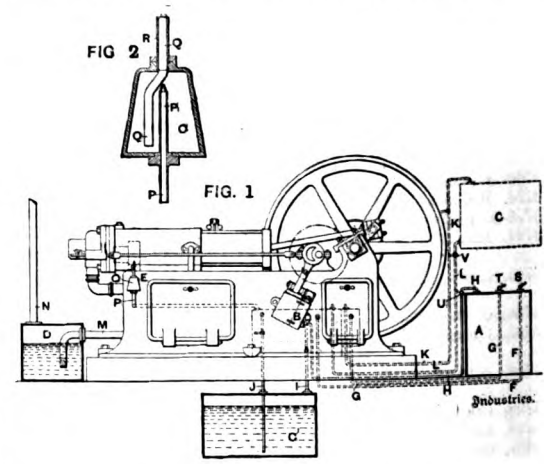
Moulds for Bricks.—*J. G. Parker, London.*—Instead of making the pressure mould of a brick machine with solid sides and bottoms, the inventor makes the lower parts of the sides and the bottom perforated. A body of grit sand or gravel is placed in the mould of sufficient height to cover the perforation in the sides. Above this body of grit is placed a perforated or porous slab of the internal dimensions of the mould and resting upon the body of grit. Over this slab is spread a piece of fine calico. The object of thus preparing the mould is to provide passages for the escape of moisture from the clay as the brick is being formed in the upper part of the mould. The brick is delivered from the mould in the usual manner. Claim: The method described of making moulds with perforated sides or bottoms to be filled with granulated filtering material in the manner described.—No. 4881. March 20th, 1890. 6*d*.

Gas Engines.—*H. H. Lake, London.* (*J. C. Beckfield & A. Schmid, Pennsylvania, U.S.A.*).—The principal object of this invention is to ensure the more uniform expenditure of the driving power in gas engines. The three illustrations show respectively a sectional front elevation, a side elevation, and plan of an engine constructed according to the invention. The engine has two cylinders D and E of different diameters; the larger, E, is termed the power cylinder, and the smaller, D, the explosive cylinder. Communication is made between the two cylinders, between the cylinder D and a series of pipes N, and between the cylinders and pipes R and S by the valve R¹. The engine is first started by the admittance of steam to the cylinders. The steam is supplied through R, and exhausted through S. When speed

has been obtained, gas and air is passed to the engine through K, and is drawn into the lower part of the cylinder E. Upon the descent of the piston H, the explosive mixture is compressed and discharged through the valve U and pipe M to storage pipes N, which are surrounded by water. From the storage pipes the mixture is drawn into the cylinder D, and when the piston G is at the bottom end of its stroke, and the piston H at its top end, communication is made between the cylinders, and the charge is exploded. The piston H is thus driven down again, compressing a fresh supply of gas and air, and the piston G ascends ready to take in a fresh explosive charge. Nine claims are made.—No. 2647. February 18th, 1890. 8*d*.

Signalling Apparatus.—*J. Fletcher, London.*—This apparatus is designed for the purpose of indicating the position of the helm of any vessel to one approaching it. A large lamp with circular front made of opal glass is fitted with a diaphram or circular piece of metal so arranged that it will travel across the larger front by the action of the helm. The disc of metal is smaller than the semi-transparent front of the lamp, and therefore when the helm is amidship a circular white ring is visible. When the helm is moved over to port or starboard side a half moon is shown either to the right or left, as the case may be. The metal disc may also be connected to engines of a steamer to show whether the engine is going astern by lifting the disc to the top, or going ahead by lowering it. By the semi-transparent nature of the front of the lamp the device may be seen in the day and at night. Claims: (1) Apparatus for signalling in which a disc or other shaped screen is, on the helm being moved, caused to traverse across an illuminated space; (2) apparatus for signalling as described.—No. 6923. April 25th, 1889. 6*d*.

Steam Engine Governors.—*J. W. Brown & W. W. Sutcliffe, New Orleans, U.S.A.*—This governor is arranged on the steam supply pipe of the engine. It consists of a turbine, situated in the steam pipe, and rotated by the passage of the steam to the engine. To the axle of this turbine are fitted centrifugal governor balls, whose sliding collar is connected to a valve regulating the supply of steam to the engine. Thus, as the rate at which the steam flows to the engine varies, the turbine varies directly in speed, the centrifugal balls rise or fall and the regulating valve is opened or shut. Seven claims are made.—No. 2691. February 19th, 1890. 8*d*.



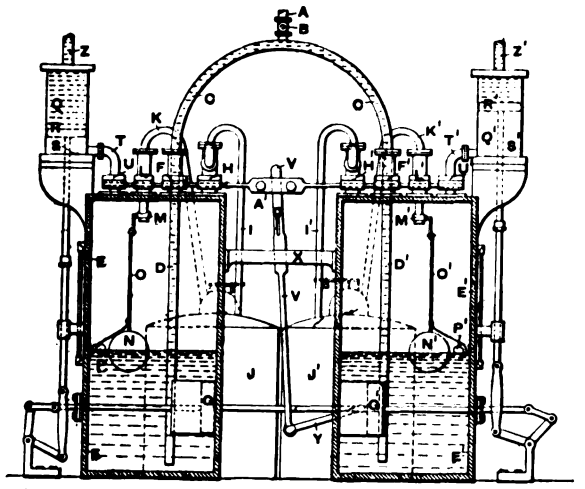
Manufacture of Clear Ice.—*W. L. Wise, London.* (*Escher, Wyss, & Co., Zurich, Switzerland*).—A rotating motion is given to the water to be frozen by external means. The freezing cell is surrounded by the freezing mixture, and it is fitted so as to turn on a vertical, horizontal, or slanting axis. The revolving motion is made continuous in one direction or reciprocal. This motion of the cell in the freezing mixture induces an active friction between the walls of the cell and the liquid to be frozen within the cell. The friction is so great that the liquid is quite freed from air during the operation of freezing, and freezes into a transparent crystal-like block. Three claims are made.—No. 5592. April 2nd, 1889. 8*d*.

Cushioning Parts of Machinery.—*A. Gibb, London.*—In applying this invention to cylinders filled with liquid to form a resistance to the movement of a piston from end to end of the cylinder, a second cylinder is arranged upon the side of the first to receive the liquid as it is discharged by the piston in the first. The second or receiving cylinder has two pistons situated at each of its ends, and they are pressed apart by two coiled springs supported upon a rod concentric with the axis of the cylinder and between the pistons. The liquid, as it is discharged from the first cylinder, passes into the receiving cylinder between one of its ends and one piston against the resistance of the springs between the pistons. The force of the springs and the suction of the piston in the first cylinder returns the liquid from the receiving cylinder to the first as its piston makes a return stroke. Claim: That by the present arrangement only one receiving accumulating cylinder is used instead of two, thereby effecting a saving of half the number of springs and tension rods, besides having the springs enclosed and the whole taking up less room.—No. 5151. March 26, 1889. 6*d*.

Water-Heating Apparatus.—*T. Bradford, Salford.*—This apparatus is constructed somewhat in the manner of a feed-water injector. The object of the invention is to make use of steam for the purpose of heating water supplied to public baths and steam laundries. The appliance is attached to the water supply pipe, and consists of a cylindrical chamber having three openings, one at each end of the chamber opposite to each other, and the third at the centre of the side of the chamber at right angles to a line drawn through the others. The water is supplied through the opening upon the side of the chamber, and steam at one of the end openings; the resulting hot water from the mixture of the two is discharged at the other end opening. The steam entrance terminates in a steam nozzle within the chamber, and the discharge opening is made smaller than the water inlet. By this construction the steam mingles with the water as it passes through the device. Claim: The improved apparatus as described for heating water by means of a jet of steam introduced into the supply pipe between the cold supply and the hot outlet.—No. 8392. May 20th, 1889. 6*d*.

Steam Boilers.—*J. F. A. Schnarrendorf, Hamburg, Germany.*—The invention is especially applicable to high-pressure boilers. Its objects are to increase the calorific effect of the burning gases and to facilitate the cleaning of all those parts liable to be fouled by the products of combustion. To withstand a high pressure the boiler is made of spherical form, the shell being composed of two semispherical parts. The fire-boxes—four in number—are arranged in the lower part of the boiler symmetrical about its vertical axis. At the junction of the pipes is attached the uptake, which is here a vertical tube. The lower part of the tube forming the uptake constitutes with the four large radiating tubes the fire-box of the boiler; the lower part of the vertical tube is divided from the upper by a damper. From the vertical tube a number of small tubes radiate to the boiler shell. The products of combustion, as they leave the fire-box, pass by these small tubes to an annular smoke-box upon the outside of the boiler shell, and then back again through similar tubes to the uptake above the damper, when they ascend and are discharged. Claims: (1) A boiler which is spherical or concoidal in form, and provided in its lower part with a number of fire-boxes developed at their junction on the upper surface of the latter into a socket connected to a fire-box plate which is adapted to receive the inner ends of boiler tubes radiating towards an annular chamber or smoke-box; (2) in combination with a boiler, the shell of which is spherical or concoidal in form, and provided in its lower part with a number of fire-boxes developed at their junction on the upper surface of the latter into a socket connected to a fire-box plate, which is adapted to receive the inner ends of boiler tubes radiating towards an annular chamber or smoke-box, a damper within the fire-box, and adjustable in any desired position.—No. 13711. August 30th, 1889. 6*d*.

Hydrocarbon Engines.—*W. D. & S. Priestman, Hull.*—This invention relates to motor engines operated by the combustion of inflammable vapour, such as petroleum or other liquid hydrocarbon mixed with air, and consists of improved means for heating the vapour-chamber preparatively to starting the engine, means for replenishing the supply of oil in the petroleum reservoir whilst the engine is running, means for purifying the exhaust gases previously to their discharge into the atmosphere,



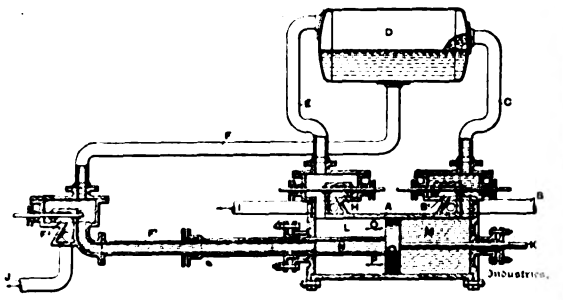
and means applicable for use in connection with firing the working charge when the ignition thereof is effected by means of a flame. In the illustrations Fig. 1 represents a side elevation of an engine embodying the improvements, and Fig. 2 a section upon the ignition lamp. Instead of employing an air-pump actuated by hand for creating sufficient pressure in the petroleum and compressed air reservoir to operate the vapour lamp before the engine is started, the inventors employ a storage vessel A, which is supplied with air from the reservoir through the pipe F or by means of a subsidiary pump B whilst the engine is in motion. When the engine is restarted it is thus only necessary to turn the cock T, and form communication between the vessel A and the petroleum reservoir, to supply the lamp with air and oil. To replenish the supply of oil in the petroleum reservoir whilst the engine is running the reservoir is connected by an air-pipe K with a closed storage tank C. The tank C is placed at a height about the reservoir to equalise the pressure in the two. By opening the cock V the oil flows by gravitation to the reservoir. The exhaust gases are purified previously to being discharged into the air by leading the exhaust pipe N to a cistern D containing water. The pipe is so arranged that the gases before

Digitized by Google

escaping pass through the water and the heavier products are thereby condensed and arrested. The lamp employed for igniting the charge is a petroleum lamp E provided with an oil tank O and supplied with air from the petroleum reservoir through the pipe P. Q is the lamp-wick. Six claims are made.—No. 6682. April 18th, 1889. 8*d*.

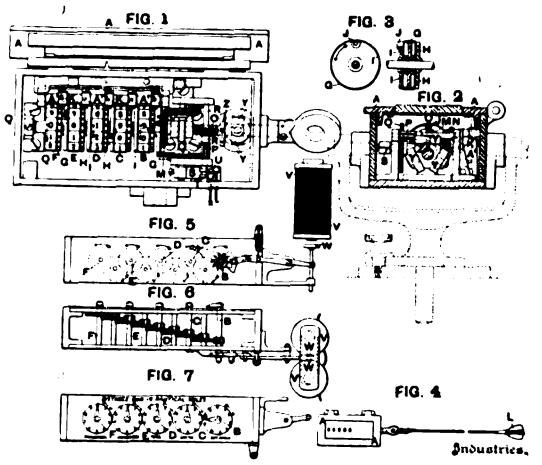
JOURNAL LUBRICATORS.—*J. T. Kirby, London.*—This lubricator works by capillary action. Under the shaft to be lubricated is a flat-bottomed vessel containing the lubricant. In the vessel is a wick-holder made of a thin sheet of metal bent into the shape of a U. The upper ends of this U-shaped holder is bent to fit the shafting, and they have cut in them serrated edges, which are bent inwards, and hold up the wicks against the sides of the shaft. The wicks consist of sheets of asbestos or woollen felt. One edge of the wicks dips into the lubricant, whilst the upper edge is held against the sides of the shaft. Six claims are made. —No. 1218. January 23rd, 1890. 6*d*.

COMPRESSED AIR GENERATORS.—*A. J. Boult, London. (L. Bontemps & P. Bontet, Paris.)*—The energy utilised for the purpose of compressing the air is that due to a constant column of water. The machine is of duplex form, and the pressure of the column of water transferred from one compressing chamber to the other alternately. The illustration shows a sectional elevation of the machine. E E¹ are the compressing chambers; J J¹ the reservoirs for compressed air; Q Q¹ air cylinders for supplying air to the compressors; G G¹ pistons for compressing the air; A the pipe sustaining the column of water, and having branch pipes C leading to each compressing chamber; U, F, H, and U¹, F¹, H¹ are valves controlling respectively the supply of air and water to the compressing chambers, and the escape of air from the compressing chambers to the reservoirs: the valves are actuated by the tappets and rods A¹ V. The machine works in the following manner: The various parts being in the positions illustrated, air will be passing from the cylinder Q to the chamber E whilst water enters from the pipe A, and by the pressure due to its



height forces the piston G to the right. The motion of G is transmitted to G¹, and the latter thereby compresses the air in E¹, and causes it to escape to the reservoir J¹, whose valve H¹ is open. At the same time the piston R descends and passes air into the chamber E, whilst the piston R¹ ascends and draws a supply of air into its cylinder through the flap valve S¹. The tappet arrangement is also operated by the motion of the piston G, and as it approaches the end of its stroke shifts the valves so that those previously open are shut. An action now commences upon the right side of the machine similar to that upon the left side. When the water exceeds a certain height a float arrangement N and N¹ opens a valve and discharges the water from the chambers E E¹. Eight claims are made.—No. 1893. February 2nd, 1889. 8*d*.

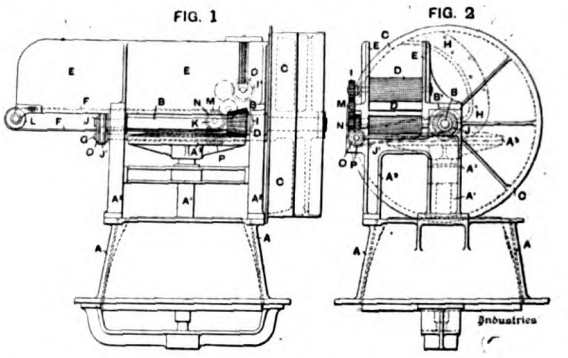
LOOMS.—*G. Thomson & J. Hampshire, Huddersfield.*—The object of this invention is to diminish the shock caused by the momentum of the shuttle of a power loom at each end of its traverse or pick, and is chiefly applicable to under pick looms. The two picking arms are connected by straps which are looped upon the arms and connected by wire provided with one or more screw couplings for adjustment. The wire or rod is strained sufficiently to cause the picking arms when at rest to be drawn a slight distance towards the centre line of the loom in order that when either of the pickers is struck by the shuttle a small space is left in which the picker springs back. The leather loops by which the check wires are attached to the picking arms are on one side of the loom secured to the picking arm above its pivot and upon the other side below its pivot. By this arrangement the lower part of the picking arm moves outwards when the shuttle is struck, and draws the non-striking picking arm inwards a short distance; in this position the non-striking picker receives the shock of the shuttle. Claims: (1) For the purpose of checking or diminishing the force of the blow given by the shuttles of power looms at each end of their traverse or pick a connecting wire or rod provided with screw couplings for adjustment, each wire being attached to a picking arm by means of a strap and loop of leather upon one side of the loom above the fulcrum upon which the picking arm is hinged, and the same wire is connected to the picking arm upon the other side of the loom below the fulcrum; (2) in a check motion for the shuttles of looms the combination of the check-wire or rod, the screw couplings, and the straps and loops of leather, with the picking arms and the springs for returning the arms into their striking position; (3) the general arrangement of the parts comprising the check motion as described.—No. 3149. February 27th, 1890. 6*d*.



STEEL.—*M. F. Coomes & A. W. Hyde, Louisville, U.S.A.*—The object is to effect a rapid carburisation of malleable cast iron or of low carbon steel by the use of certain carbon compounds which are readily decomposed by contact with heated metal. Suitable carbo-hydrates for the process are sugars, syrups of any kind, molasses, treacle, and honey. As an equivalent and substitute for the above any of the organic acids which result from the oxidation of glycols may be employed. Any of these substances are dissolved in water or milk, forming a bath into which the metal to be carburised is placed at a white heat. The metal parts with its heat, which decomposes the carbo-hydrate, setting free the carbon, which is absorbed and chemically united with the metal. Four claims are made.—No. 2981. February 25th, 1890. 4*d*.

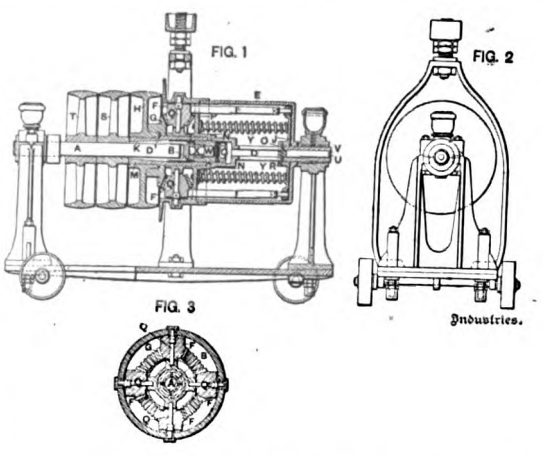
ALTERING THE PROPORTION OF MIXED GASES.—*S. Fox & E. Blass, Leeds.*—The proportion of the gases is altered by compressing the mixture in the presence of a suitable absorbent, such as water, and thus eliminating quantities of the respective gases. A longitudinal sectional side elevation of the apparatus

used for this purpose is shown in the illustration; it works in the following manner:—The piston O, when moving in the direction of the arrow P, draws in through the pipe B and valve B¹ a charge of the gas and water. On the return stroke of the piston this charge is delivered under pressure through the pipe C to the reservoir D. The water, with the gases it has absorbed, are drawn from the reservoir D through the pipes and valve F F¹ and F² into the hollow prolongation N of the piston O as the latter makes its stroke to the right. Upon the return of the piston to the left, the water and contents are forced out through the pipe F¹ and valve F² to the delivery pipe J. The gases in the altered or purified state are removed from the reservoir through the pipe E and valve H, and discharged through I by the action of the piston in the back of the cylinder L. Claims: (1) The altering the proportions of gaseous mixtures by compressing them intimately mixed with water substantially as herein set forth; (2) the apparatus or its equivalent substantially as described and illustrated for the purpose specified.—No. 6129. April 10th 1889. 6*d*.



LOG OR CURRENT METER.—*D. McGregor, Jun., Glasgow.*—This log or meter is an improved instrument for recording the distance a vessel travels through the water, or it may be used for ascertaining the speed of currents of water or other like purposes. The movement or wheelwork is contained in a strong metal case which by suitable fittings accommodates itself to and neutralises any motion due to the rolling or pitching of the vessel. The illustrations show Fig. 1a plan of the meter with case open, Fig. 2 a sectional end elevation, Fig. 3 views of a recording drum; Fig 4 shows a plan of the meter on a reduced scale; Figs. 5, 6, and 7 show an indicator with dials and pointers provided with electrical means for communicating the state of the meter on the bridge of the vessel or other parts. Referring to Figs. 1, 2, 3, and 4, the lid A is provided with apertures through which one figure upon each drum is alone visible at a time. Five recording drums are shown; the first B makes one revolution in one mile; the second C one revolution in ten miles; the third D one in a

hundred miles; and so with E and F, increasing by multiples of ten, ten being the number of divisions on each drum. Each drum G (Fig. 3) has secured to it a driving toothed wheel H and a disc I having a single-toothed recess J. The drums are supported upon a shaft in the centre of the box, and the toothed wheels and discs are made to gear with double-toothed pinions K loose upon a counter-shaft A¹. At each revolution of a disc H the recess J engages with a tooth of a pinion K and turns the pinion sufficiently to rotate the toothed wheel I on an adjacent recording drum a distance of one recording figure. The first disc is revolved by means of a rotator L (Fig. 4) whose motion is transmitted to the disc through the bevel gearing M and N. Upon a transverse shaft R is a worm wheel O, which, with the pinions P and Q, revolve a projection S, and by the spring contacts T U connect up an electric circuit containing the electro-magnet V. The magnets V actuate by the armature W, the levers X and Y, and the wheel Z, the indicating mechanism shown in Figs. 5, 6, and 7 which is placed on the bridge or other parts of the ship. Claims: (1) A recording log, for indicating the speed and distance of a ship's motion or the velocity of a water current comprising the combination of a speed counter having a series of indicating edge numbered drums or wheels directly connected to wheel gearing which receive motion from a revolving spindle attached to a tow rope and propeller or motor rotated by the motion of the vessel or current, substantially as described in reference to and shown in Figs. 1 to 4 of the accompanying drawings; (2) in combination with the mechanism of the above-claimed recording log, an electrical make and break contact mechanism actuating speed and distance indicating dials or drums substantially as described in reference to and shown in Figs. 5, 6, and 7 of the accompanying drawings.—No. 6137. April 10th, 1889. 8*d*.



SHIPS' GANGWAYS.—*C. Townson, Montreal, Canada.*—The steps of this gangway or companion ladder are so constructed that they always assume a horizontal position. The hand rails are also automatically adjusted so that they are convenient for the hand notwithstanding the variation of the inclination of the frame. The steps are pivoted at the centre of each end to the side frame of the ladder, and upon their rear edge to two sliding rods. One end of the ladder and the sliding rods are secured to a platform, either of a trolley form when the ladder is to be transported, or to a horizontal extension of the ship's deck when it is permanently fixed to the ship. The ladder is hinged to this platform, so that it can be raised. When the ladder is raised the sliding rods hold the steps in a horizontal position. The upright standards of the rails are pivoted to the side frames of the ladder and the lower or upper part of the rails attached to the horizontal platform, so that the rails always remain parallel to the frame of the ladder. Three claims are made.—No. 3237. February 28th, 1890. 6*d*.

BARK MILLS.—*E. V. Brown, Exeter.*—In this bark mill the bark is cut transversely to the length of fibre, and, dropping from the cutting knives, is received between the grinding surfaces of the mill, where it is reduced to a condition suitable for the tanner. Fig. 1 is a side and Fig. 2 a front elevation of the machine. The driving pulley C is cup-shaped in cross section, and has fitted to its hollow sides the cutting blades H, similar to those used in chaff-cutting machines. To the shaft B of the pulley C is keyed the bevel wheel B¹, which gears into a crown wheel A³. The wheel A³ transmits rotary motion to the conical runner of the

mill. The bark is fed to the machine by laying it in the trough-like casting E. It is then advanced towards the corrugated rolls D by an endless apron F. The rolls D seize it and deliver it to the knives. The rolls D and apron F are driven off the counter-shaft G by the worm P and wheels M N I and I¹. The counter-shaft is driven off the main shaft by an endless chain J¹. The bark as it leaves the knives falls to the conical bark mill A of ordinary construction. Claim: The arrangement of cutting and grinding mechanism described constituting the improved compound bark mill.—No. 7724. May 8th, 1889. 8*d*.

DYNAMOMETERS.—*A. Ackermann, Grellingen, Switzerland.*—A rotating dynamometer is here described, for transmitting and indicating power between the driving shaft and the machine, whose power it is desired to measure. It consists of a drum E carrying bevel pinions F arranged radially within it. The pinions F gear with a bevel wheel G fixed to the loose pulley H, and they are connected by bands I to a disc J movable upon the mandrel D. A resistance to the motion of the plate is caused by spiral springs Y, and the plate is connected to a rod in the interior of the mandrel D. The power transmitted by the dynamometer to the machine is measured by the winding of the bands

on the bevel pinions and the displacement of the plate J. A graduated scale is introduced into the hollow mandrel, and indicates in horse-power the work performed by the displacement of a rod connected to the plate. The pulleys T and S are those used to drive the dynamometer, whilst the pulley H is that used to transmit motion to the machine whose consumption of power is to be tested. In the enlarged part of the hollow mandrel is arranged a coupling device for bringing the machine into work as required. Three claims are made.—No. 8318. May 18th, 1889. October 20th, 1888. 8*d*.

Digitized by Google

Bottle Washing Mechanism.—*G. Burges, Jun., Sheffield.*—The machine consists of an intermittently rotating bottle-carrier having recesses in which the bottles are soaked and automatically brushed, and of mechanism for brushing the bottles internally and externally, and finally delivering them on to a table by the side of the machine. In the illustrations Fig. 1 is a side elevation, Fig. 2 a back elevation, and Fig. 3 a front elevation of the machine. The bottle-carrier A is a drum-like casting, having cylindrical chambers B for the bottle. The carrier is supported by tubular journals in a water tank C. A ratchet wheel D is secured to the side of the carrier A, the number of teeth corresponding to the number of rows of bottle chambers B, so that by rotating the carrier the distance of one tooth a fresh row of bottles are brought under action. The mechanism for driving the carrier by the ratchet wheel consists of the parts E, F, G, H, I, J, K, and L, operating the pawl M, and causing it to advance a

FIG. 1

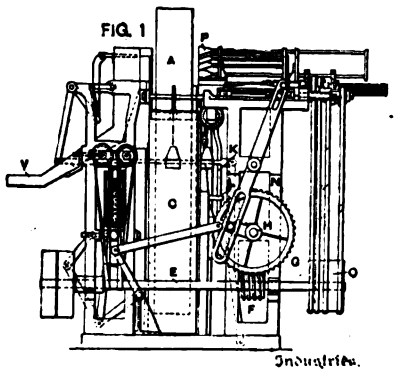


FIG. 2

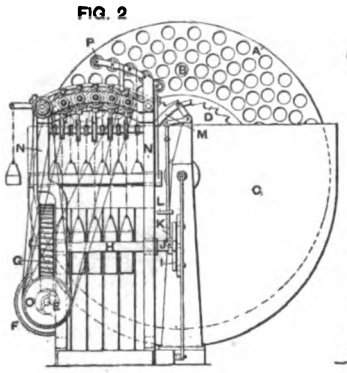

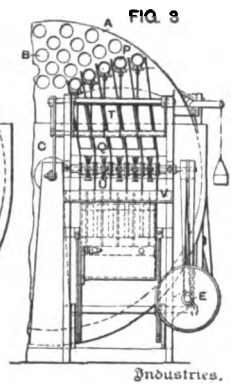

FIG. 3

tooth each revolution of the crank plate I. At the back of the machine is a frame N which carries a series of rotating brushes corresponding to the holes in the carrier. The brushes are rotated by bands upon the pulley O, and they are intermittently advanced in the direction of their lengths for brushing the interior of the bottles in one row of holes when the carrier is at rest, and are retired prior to the next movement of the carrier. Above the brushing mechanism is arranged an equal number of bottle-ejectors P, which are advanced in the manner of the brushes and eject the previously washed bottles. The bottles as they are ejected from the carrier are conducted mouth downwards through the channels Q to the externally brushing brushes, and then to the rinsing pipes. Each of the channels Q is provided with a shutter T, which are simultaneously opened to pass the bottles to the brushes, and also to simultaneously press the bottles, previously brushed and rinsed, over into the front continuation U of the channels Q down which they slide to the delivery table V. Nine claims are made.—No. 19801. December 9th, 1889. 8*d.*

Hydraulic Presses.—*C. A. Piat, Paris.*—According to this invention the actions and reactions take place in the interior of the press, and the press is suspended from the extremity of a swing arm instead of a jib or ordinary crane; it can thus be readily manipulated and can be used in connection with several platforms or tables. Or the press may, with the same object, be

FIG. 1

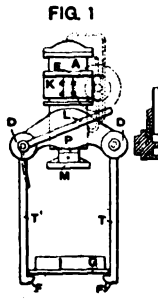

FIG. 3

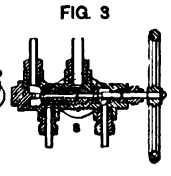

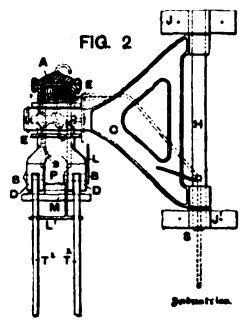

FIG. 2

carried by rails. The support, whether swing arm or rails, has only to withstand the mere weight of the apparatus, and is not affected by the internal strains which may be developed, as is the case in ordinary presses where the action takes place between a bed-piece or support and a head-piece. In the accompanying illustrations Figs. 1 and 2 are respectively side and end elevations of the apparatus. A is a hydraulic cylinder supported by a shoulder E upon the collar K of a pivoted frame C. In this cylinder works a piston P carrying a compressing plate M. The ascent and descent of this piston are effected by means of water under pressure distributed by distributing apparatus which may be of the kind described in the specification of a former patent, No. 7026 of 1886, and of which a longitudinal axial action is shown in Fig. 3. The hydraulic distributor is shown in position by the dotted lines. The lower end of the cylinder is formed with a cross-head which carries the hooks T T^1 T^2. These hooks engage with the underside of a table G, upon which the material is placed to be pressed. A hand lever L enables the operator to throw out the two hooks T^1 T^2 from under the table, to facilitate the removal and placing in position of the table. The vertical axis or pillar H, which supports the frame C and turns or travels therewith, is provided with a stuffing box at one end for the reception of the pipe supplying the pressure water. The exhaust pipe may in like manner pass out through the same end or through the other end, or it may freely eject the exhaust water whilst following the motion of the apparatus. Claims: (1) Tie-bars such as T T^1 each provided with a hook such as F and freely suspended from an axis such as B passing through a lug such as D on the cylinder A, in combination with an operating lever such as L and a press table G; (2) the cylinder A with collars E E in combination with a frame C, having a collar K fitting loosely between the collars E E, the said frame turning with the axis H, which has a stuffing box S, through which passes the pipe that supplies the pressure water to the distributor S of the press; (3) the combination of the piston P, the hydraulic distributor S, and the collar K surrounding the cylinder A, the whole so arranged as to permit of the rotary movement of the apparatus in conjunction with the up and down movement of the piston.—No. 16686. October 22nd, 1889. 8*d.*

ELECTRICITY.

Dynamos and Motors.—*James Swinburne, Wimbledon.*—This invention refers to direct and to alternating current dynamos and motors. A sort of subsidiary armature core, consisting of a ring of wires or discs, is placed inside the connections to the commutator, so that the commutator connections are on its outer surface, or in grooves milled out of the discs. A little field magnet is arranged so that the connections come under it so as to have the necessary electromotive force induced at the right time or place. An alternating current motor is designed so that at any instant its back electromotive force is just less than the electromotive force on its terminals by enough to cause the armature current needed to give the power. At no load such a motor should give a back electromotive force which at any instant is almost exactly equal to the terminal electromotive force. At full load the field is weakened enough to let the necessary current pass, so that the motor does not need to lag much and weaken its field by the reaction of its armature current. In the case of a motor, the exciting circuits are so arranged that at no load the field excitation gives a back electromotive force approximately equal to the electromotive force in the mains. If it has very nearly the same back electromotive force the motor at no load becomes cophasedly synchronised and takes just enough current to drive it and give power for excitation. When load is put on the motor begins to lag. The armature current then reacts on the fields and weakens them; this weakens the field excitation, as the exciting coils are influenced by the same field magnets, and the field can thus be weakened enough without much lag. The exciting armature circuits are coupled up to a commutator, as in an ordinary closed or open armature circuit direct current machine. The field excitation is then affected by the main armature current's reaction on the field magnets. The field excitation may be lessened more directly at full load by passing the main current of the motor round the field magnets after commutation. All these methods depend

FIG. 1.

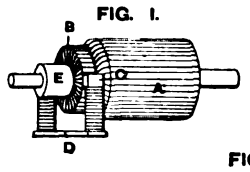

FIG. 2.

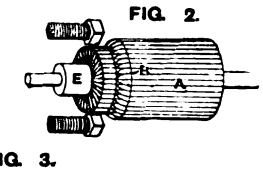

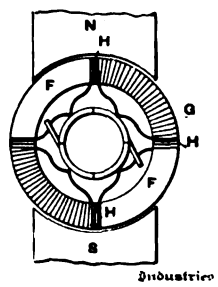

FIG. 3.

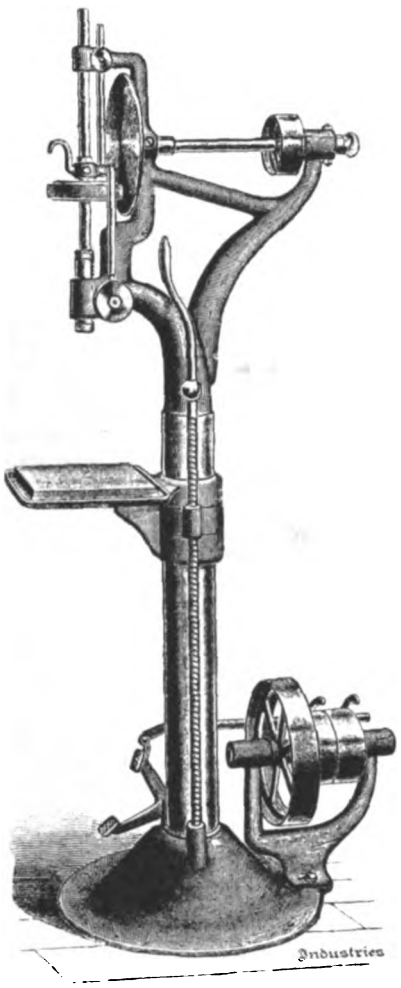
for their final adjustment on the lagging of the motor as the load increases, but instead of being considerable the lag is small, because the current turns round the field magnets are fewer at full load than at light loads. To start an alternating motor, the inventor uses one of the methods already mentioned by him in earlier patent specifications—namely, starting by connecting batteries with the direct current exciter; starting by turning the alternating current into the exciter, which has, preferably in this case, laminated magnets; or starting by connecting the armature and field magnets of the motor with the alternating current. Fig. 1 is a diagram of a reversing armature and magnet attached to an armature and commutator. A is the armature of the dynamo or motor and E the commutator. B is the reversing armature core, in the periphery of which the commutator connections are embedded, and C is one pole of the reversing magnet. A yoke D is shown, but in practice the vertical parts of the magnet are mounted on the bed-plate. Fig. 3 is a diagram showing the commutator sections and connections of alternating current motors. F is a ring armature. For the sake of simplicity a two-pole machine is taken, though in practice it is better to have six or more, so that the speed is not too great. G are the active coils or main coils of the machine. They are connected to collecting rings as usual, which are not shown in the diagrams. H are the exciting coils of the armature. In Fig. 3 the exciting coils are connected up as in a Gramme ring. Claims: A generator or motor for direct currents, having—(1) A reversing armature core with the commutator connections embedded in it; (2) a reversing armature with the commutator connections thin where they pass through the reversing field; (3) a reversing armature core with each commutator connection passing over the outside only once, substantially as set forth (4) reversing magnets adjustable as to position substantially as described. A synchronising alternating current motor—(5) in which the current turns on the field magnets are decreased when the load increases; (6) excited from its own armature; (7) a self-exciting alternating generator or motor with two or more exciting coils on the armature giving currents differing in phase, substantially as and for the purposes set forth.—No. 3424. February 26th, 1889. 8*d.*

Electrical Firing Apparatus.—*R. Morris, Blackheath, London.*—The firing is effected by a blow from a spring striker on a percussion cap. There is attached to the breech of the weapon a tube containing a spring striker, which can be drawn back by a handle at the breech end of the tube. When the striker is drawn fully back, compressing the spring, a sear in the form of a stud, sliding in a hole of the tube transversely to the striker, is caused by a spring to engage in a recess of the striker and hold it back in a cocked position. The sear is connected with certain freedom of motion to the armature of an electromagnet which is fixed on the side of the tube. One end of the armature is hinged to one end of the core of the electromagnet, and the other end of the armature is held by a spring at some distance from the other end of the core. An arm projecting from the armature has a pin entering a circularly slotted hole in the sear. The coil of the electromagnet is connected by two insulated wires to a battery through a contact key which may be at a distance. On depressing this key a current passes through the coil of the electromagnet, and the armature is attracted. During the first part of the movement of the armature its pin moves freely in the slot of the sear, but at the last part of its movement this pin, meeting the end of the slot of the sear, pulls the sear outward, releasing the striker, which is thereupon forced forward by its spring, and, striking the cap, explodes the charge. Claim: Electric firing apparatus for ordnance, consisting of a tube attached to the breech of the gun, having within it a sliding spring striker, in combination with an electromagnet, armature lever, and transversely sliding sear constructed and operating as described.—No. 7780. May 9th, 1889. 6*d.*

CHEMISTRY.

Extraction of Gold.—*J. H. Pollok, Glasgow.*—This invention consists in the continuous application of hydraulic pressure to a rotating vessel, in which the process of chlorination is being conducted, by means of a pipe leading from an accumulator, pump, ejector, or other water-forcing device to the cylinder. The pipe passes through the centre of rotation of one end of the cylinder, to which it is attached and kept tight by a suitable packing box. In operating, the ore is first crushed, concentrated, roasted, or otherwise prepared, and is then placed in the cylinder with the necessary reagents. The air is next removed from the cylinder, and the water supply turned on. When the cylinder is completely filled with ore, reagents, and water, it is closed and revolved. The water maintains a constant pressure in the cylinder during chlorination. When the chlorination is completed the valve on the hydraulic press supply pipe is closed, and the excess of chlorine blown off by a valve provided for the purpose. The contents are next discharged from the cylinder to a filter, when the solution of gold is drawn off and the gold precipitated. Claim: The application, as described, of continuous hydraulic pressure to the revolving cylinder wherein the wet method of extracting gold by chlorine, bromine, or iodine is conducted by means of a pipe passing through the centre of rotation of one end of the cylinder, and connected to the said end of a suitable packing box so as not to interfere with the revolving of the cylinder.—No. 5578. April 2nd, 1889.

MISCELLANEOUS.



Speaking Tubes.—*G. King, London.* (*H. A. Cutmore, Melbourne.*)—The mouth-piece of this speaking tube is of the ordinary construction, but it is used only as a transmitter. In the tube, close behind the mouth-piece, is a cock of usual form, which closes normally the end of the tube. The cock is made hollow, and its interior communicates with a branch pipe, which answers the purpose of a receiver. The branch pipe is secured to the plug of the cock, and by its weight the pipe normally hangs downwards and closes the cock. When the branch pipe is raised, however, in a horizontal position to the ear of the operator the cock is opened, and communication formed between the speaking pipe and branch tube and between the pipe and its transmitter or mouth-piece. Behind the cock is situated, on the upper part of the tube, a compressible bulb, having communication with the tube, and provided with a signalling whistle or call. To use the tube, the operator first attracts the attention of the recipient by pressing the flexible bulb. This action blows the whistle in the bulb at the other end, and conversation can then be carried on by raising the branch pipes to the operators' ears. Claims: (1) In a speaking tube the combination with a cock plug of a hollow branch or arm, communicating with the interior of the plug, and carrying an ear-piece and a mouth-piece; (2) in a speaking tube the combination with a stop-cock or equivalent device, adapted to close or unclose the tube of a signalling device; (3) in a speaking tube the combination with a stop-cock adapted to close or unclose the tube of an ear or mouth piece connected with the interior, and movable with plug of said cock, and a mouth or ear piece upon said piece; (4) in a speaking tube a cock with a parallel plug and stops, adapted to allow of the plug being inserted into the barrel from either side; (5) the combination with a speaking tube of a cock or equivalent for closing or unclosing the tube, and operated by an arm or tube which carries the mouth or ear piece; (6) the combination and arrangement of parts described; (7) in a speaking tube the combination with means for stopping the tube of a call-whistle or equivalent.—No. 4787. March 18th, 1889. 8*d.*

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

SENSITIVE DRILLING MACHINE.

The drilling machine here illustrated is specially adapted for delicate and accurate work, where exact adjustment and rapid and effective operation are essential. The machine is made by the W. F. & John Barnes Company, of Rockford, Illinois, U.S.A. All the adjustments of power and speed can be made without removing the belts or stopping the machine. By means of the hand

screw shown, the table can readily be moved and fixed at any required height. The principal dimensions are: Extreme height from the base to the drill spindle, 46in.; the greatest space between the table and spindle, 36in.; diameters of column and spindle, $3\frac{1}{2}$in. and $\frac{3}{4}$in. respectively; vertical motion of spindle, $3\frac{1}{2}$in. The machine weighs 170lb., and is capable of running at any speed up to 1,600 revolutions per minute.

THE S.S. "PRINS WILLEM II."

On pages 436 and 437 we illustrate the engines of the steamship "Prins Willem II.," the general arrangement of whose engines and boilers we illustrated in last week's issue. We need not repeat the description of the engines which we then gave, but we give as follows their leading dimensions and particulars:—Diameter of cylinders, 22in., 34in., and 56in.; stroke, 40in.; initial steam pressure, 160lb. per sq. in.; indicated horse-power, 1,235, at 72 revolutions per minute.

THE INSTITUTION OF MECHANICAL ENGINEERS.

The spring meeting of this Institution was held on Thursday and Friday, the 1st and 2nd inst., at the Institution of Civil Engineers, Great George Street, Westminster, Mr. Joseph Tomlinson, President, in the chair. After it had been announced that the Prince of Wales had been elected an honorary life member of the Institution in recognition of the interest he has always taken in mechanical progress, the President delivered his inaugural address, which we publish herewith in full. There is no man living, with the exception, perhaps, of Mr. Edward Woods, who has had such a long experience in railway work as the President, and the reminiscences which formed the substance of his address are therefore of special interest.

PRESIDENT'S ADDRESS.

As I have been a railway man nearly all my working life, I think the best subject I could choose would be "Railway Locomotion" of the past and present. My recollection and practice lead me back to the early days of the locomotive engine, though not to the very earliest. My first knowledge of them as a boy dates back to the year 1837. My father being at the time passenger superintendent of the Stockton and Darlington Railway, it was nothing extraordinary that, with my predilection for mechanics, my desire to go to the old Shildon Works should be gratified. Timothy Hackworth, the then locomotive superintendent and also the contractor for the working of the railway, was pleased to agree that I should have the "run of the shops"; and thus I began my working life.

The locomotive engines in use in the early days of the Stockton and Darlington Railway differed widely in every respect from those of to-day. Nearly all, I daresay, have seen old "Locomotion," now on the pedestal in front of the North Road Station at Darlington. This engine was one of three which were first placed on the railway. Two only survived to the time I first knew it. It is now as it was delivered to the railway; but the boiler *is not* as I knew it at first. When first put to work it would not make steam; and the fire tube had to be taken out and replaced by a return tube, similar to what is now, or was until lately, used in the boilers of north-country tug boats. When this had been done its load was composed of 16 waggons, weighing empty about 27 cwt. each, or about 22 tons for the train. This was its load from Middlesbrough up the hill to Shildon; and down the hill from Shildon to Middlesbrough it took the same number of waggons loaded, each carrying 53 cwt. of coal, or about 64 tons for the train. The weight of engine and two tenders loaded with coal and water was about 15 tons. There is unfortunately no record of the consumption of coal for this early period; but I think I may say, from having helped to put the coal on the tender, that 16 cwt. to 17 cwt. were consumed in 48 miles, or about 40lb. per engine-mile, the principal part of which was consumed on the up-hill journey. This engine had two cylinders of 10in. diameter and 24in. stroke, half of each being inside the boiler. It had a cross-head to each cylinder, and thus four connecting-rods and two coupling-rods. It had four wheels of 4ft. diameter coupled. There were only two eccentrics, which had to be changed in position for back and forward gear, and the engine had to be started by hand-gearing. There was no brake on either engine or tenders. The steam pressure was from 30lb. to 35lb. Necessarily the engine had no springs; and the axles ran in cast-iron plummer-blocks. The pistons were packed with a spun-yarn gasket plaited square, which was tightened by a piece of box-wood and a hammer whenever required; this was done by the driver and fireman themselves.

The next type of engine was the "Royal George," with six wheels coupled, 4ft. diameter. Like its predecessors, and many types besides, it had vertical cylinders, of about 11in. diameter, 18in. stroke, and steam pressure about 40lb. The boiler was of the return-flue type, the fire-door and chimney being at the same end. It had two four-wheeled tenders, with ordinary chilled-face waggon-wheels keyed on their axles with wooden and iron wedges. One tender, working first up-hill, carried the water in one or two large barrels; the other tender carried coal with which the firing was done. Like the first engine, this also had only two eccentrics. The leading axle, to which were connected the cylinders, had no springs; but there were springs to the two other pair of wheels. The engine was carried, like its predecessor, in cast-iron plummer-blocks. The heating surface would be about 120 square feet, not counting the underside of the grate. The load up the hill from Middlesbrough to Shildon was 24 waggons empty, or about 33 tons; and down the hill the same number of waggons loaded, or 96 tons. The speed both up and down was about seven to eight miles an hour.

The next type was, like the earlier engines, made with vertical cylinders, but with a new class of boiler. It had a boiler partly of tubes and partly a flue, similar to what is now used for small engines, half the boiler having a flue, and then the tubes carried on to the end into a smoke-box. This brought the chimney to the same end as the cylinders. These engines, of which I think there were six, were, as far as I remember, not favourites, and the load had still to be limited to twenty-four waggons. Instead of the ordinary wheels of cast iron, it had wheels made with a cast-iron boss and wood spokes. The tires were of iron, and of the same size—namely, 4ft.

The next type was also a departure from the old type in many respects. The boiler was greatly improved, and went by the name of the "Napier" boiler; it had one straight flue for containing the grate, about 9ft. long; at the end was a combustion chamber, from which about a hundred tubes came back by the sides of the main flue to the chimney. The engine, too, was very much modified. The cylinders were still vertical, but worked on to an independent shaft fitted with cranks, and from thence the power was carried to the wheels by three coupling-rods on each side. The cylinders were about 14in. diameter and 16in. stroke. The steam pressure had also increased to 60lb., and the load was increased to thirty-two waggons, or 44 tons up hill and 128 tons down. This engine had no slide bars, the piston-rod being guided by a parallel motion. The principal defect was that, owing to keeping the centre of gravity low, very short connecting-rods had to be used, not more than three lengths of the crank. Nevertheless, this class of engine was always used to run the passenger trains when any accident or shortness of power rendered it necessary. This engine also had two tenders and only two eccentrics.

The next type of engine was made with inclined cylinders of somewhat larger diameter and stroke, but with the same size wheels. This enabled springs to be used, and many engines of this class were added subsequently. The boiler was longer, though of the same type. This engine took the increased load of 32 waggons. Like the earlier engines this had two tenders, one for water and the other for coal, but no brake.

The wheels of all the classes I have described were of cast iron, and were made in two parts—namely, the boss, which was keyed on the axle, and outside a cast-iron ring to take the tire. This ring was secured to the boss by oak filling-pieces; and after being wedged tight with steel wedges, the wood was covered by a cap inside and out, and a small bolt was put through to prevent the wedges from coming out. This style of wheel was used nearly to the year 1850, and on some old engines after that date.

I have hitherto spoken only of mineral and goods engines; I now come to the class of passenger engines in use at the time I was a lad. Several of the early engines were somewhat similar to the engines of the Liverpool and Manchester Railway, on four wheels; one pair of drivers, with 11in. to 12in. cylinders by 16in. to 18in. stroke, and about 4ft. 6in. to 5ft. wheels; but there was one engine, built, I believe, by Kitching, of Darlington, which has been seen by very few of the engineers now living. It was called the "Swift," and was of small power, about 10in. cylinders by 18in. stroke, with 4ft. wheels coupled, and steam about 50lb. The cylinders were vertical between the two pairs of coupled drivers, and worked on to an independent shaft. When I knew it, the trains between Middlesbrough and Stockton were worked with it. It seemed to me to have been the model from which Mr. Crampton took the idea for his engines of the "Lablache" class, which were put by him in later years on the Great Northern, the South Eastern, and the London, Chatham, and Dover Railways, though he used a crank-shaft and large wheels and greater power; but the idea of the designer of the "Swift" had doubtless been to take the shocks of working away from the power-shaft.

I have now also to describe another engine for passenger train work, designed by the late Timothy Hackworth, and the only one of its class ever made for England, though a somewhat larger one was made and sent to Russia. This engine, the "Arrow," was the first made at Shildon, with what may now be taken as a locomotive boiler—that is, with a fire-box and tubes. The peculiarities of its construction were that it had cylinders of 17in. diameter by 9in. stroke, and 5ft. driving wheels. It was a six-wheeled engine, with single drivers. It was supplied with a cross shaft, on which were hung two solid cast-iron wheels. On each end of this shaft a lever was attached, by which the driver and fireman could pull down the solid or friction wheels between the periphery of the driving and trailing wheels, thus temporarily connecting by friction the large drivers and the small trailing wheels; in other words, converting a single engine into a coupled one, when needed by greasy rails. The engine, as will be clearly understood, was a bad starter, and never did any good service. Many years after it was built I happened to be in the North, and inquiring about my old friends I was informed that the "Arrow" was still at work, but that the short crank had been taken out, and a 9in. put in, and this had been done while still keeping the same cylinders. It was effected by putting in a lever, the top end of which was fixed on the boiler bottom; the piston-rod took hold of the middle of its length, and from the bottom end the small end of the connecting-rod was worked. I need hardly say that such a scheme did not emanate from the brain of Timothy Hackworth, but was, as I heard, the idea of a draper in Darlington.

All the engines up to and including the "Swift," which was built in 1836 or thereabouts, had only two eccentrics, which of course necessitated hand-working to start in either direction. This of itself required a practised hand to do, and would bother nearly every engine-man of to-day. There was no brake of any kind on engine or tenders, and the only way of controlling the trains down the banks was to put the engine out of gear, or for the fireman to drop off the engine, and let down as many waggon brakes as he thought necessary; and when they had to be taken off, he had to repeat the operation of getting off and lifting them, he himself then getting on the last waggon of which the brake had been down, and walking along the top of the coals back to his engine.

In my early days the engines were worked by contract by the driver, who found coal, oil, and every requisite, and was paid by ton of coal moved. The driver had two men in his pay, one a "driver-fireman" and the other a "fireman." The steam was got up on Sunday night by the fireman; and the driver and he ran the first train on Monday morning from Shildon to Middlesbrough, the then port of shipment. On the return to Shildon in about eight or nine hours, the fireman went home, and the driver with his "driver-fireman" ran the second trip; and on the completion of the second trip the "driver" went home, and the "driver-fireman" took charge as driver, and the "fireman" who had been resting resumed duty as fireman, and this system was followed day after day. The other duties of these men was somewhat as follows:—On the return after a trip the engine was taken to the coal depôt, and coaled with a shovel by the men themselves ready for the next trip. If traffic was plentiful the stay was short, and after a meal the engine was off again. There was no time-table. After going about a mile from Shildon all the waggons had to be oiled, as there were no grease boxes; the engine was slowed down on the level to about three or four miles an hour, and the two men got down, one on each side, with his oil-can and a hazel stick about three feet long, at the end of which a piece of oakum was tied; and with this the underside of each journal running in a cast-iron plummer-block was carefully oiled. After all were done, they got on the top of the last loaded waggon and walked back to the engine, and away they went. This was repeated after about twelve miles, when going in both directions. There was no guard and no brake-van, and so all depended on themselves. As there was no van, it was necessary in the day-time to put a board up on the last waggon, so as to be sure they had not lost any of the train. At night a large pan of fire was affixed to the front of the tender and to the last waggon for the same purpose; and it was the duty of the fireman to keep both alight. There were no signals and no pointsmen, each man taking care of himself and his train, and keeping out of the way of the few passenger trains run.

No passenger trains were run on Sundays, except between Darlington and Stockton once each way, which were worked by a horse. The carriage was on four wheels without springs, and was made to carry six inside and fourteen outside, including the coachman. It was like an old ordinary road stage coach with two front ends. The ordinary passenger trains on week-days had one first-class with three bodies, which could carry eighteen passengers; and one second-class, also with three bodies, which could carry twenty-four passengers; these two were attached at Darlington to the train which came from Shildon, and were put off at the junction at Stockton. The engine coming from Shildon brought a composite carriage with one first-class and two second-class bodies, or twenty-two seats, which was run on to Middlesbrough. The speed, including stoppages, averaged, say, 16 miles per hour for the whole journey of 24 miles.

One engine not already described, which was also put on the old line, was the first goods engine with a crank-shaft, a fire-box proper, and a tubular boiler. It was built by Kitching, of Darlington, about 1838, and was called the "Queen." It had four

Digitized by Google

wheels only, with cylinders below the level of the axles and inclined upwards, 13in. diameter and 18in. stroke, and outside frames. All the wheels were coupled, and were of wrought iron. This engine was very similar to engines made about 1839 and 1840, and put on many other railways; it was used for years, but with a pair of small wheels added behind.

The "Clarence" Railway, which is now a part of the present "North Eastern," had mineral engines at starting very similar to those I have described. This line ran from Coxhoe to Port Clarence, with a branch to the old line, and was a rival to it; and hence any coal from Shildon to Simpasture, the junction, had to be worked by horses, as it had no running powers, and the Stockton and Darlington would not supply engines. Four waggons were drawn by one horse, and there was attached to the end what was called a "dandy cart," into which the horse was trained to put himself when the loaded waggons would run by gravity. The first outside cylinder engine ever made with horizontal cylinders was put on this Clarence line, and was built by Hackworth and Downing on Shildon bank top. This Hackworth was a brother of Timothy, and afterwards started with Mr. Fossick the works at Stockton now known as "Blair's." The engine had the usual return-flue type of boiler, with six wheels coupled, and cylinders of 13in. or 14in. diameter and 20in. or 22in. stroke. Up to this time all the mineral engines were innocent of framing as it is now understood; all the parts for doing the work of drawing and carrying were attached to the boiler, and hence all were as light as could be made.

About the time I first began to work a stir was being made in the matter of railways, and several were almost simultaneously opened in England. All the various locomotive superintendents of that day having had the advantage of studying the three parent lines—the Stockton and Darlington, the Clarence, and the Liverpool and Manchester—it was not strange that many variations should be introduced, which it would be impossible to describe in detail in such an address as this. Sufficient to say that some, like Bury, adopted four-wheeled engines with inside cylinders; some, like Alexander Allan, John V. Gooch, and Francis Trevithick, adopted outside cylinders; some had small drivers, and some had large; but all of them adopted, like Allan, single drivers for passenger trains, and for many years all adopted four wheels coupled for goods.

We have now arrived at 1841 to 1842, when railways had assumed proportions never dreamt of by the early pioneers and engineers, and the work was done by different types of engines, according to the ideas of the different men who had the control. The revolution in size of engine was begun with the "battle of the gauges," in 1845, with great diversity of design, and against all sorts of difficulties, chiefly those arising from want of endurance of material in rails and tires, and was carried on at all costs till the age of Sir Henry Bessemer, followed by Sir William Siemens. The relief came by the success realised in making durable, strong, and reliable material.

I now purpose to show by a few examples how in a locomotive engine, as in other things, history has repeated itself. The first example I will give is the bogie. Every modern engineer, I think, would say that this part of an engine, in its most simple form, was first adopted by Mr. Daniel Gooch in the engines built about the year 1848 for the South Devon Railway, as detailed in Mr. D. K. Clark's volume on "Railway Machinery." That is not so, however; for the earliest bogie, in this country at least, was on an engine built by Carmichael, of Dundee, in 1833, for the Dundee and Newtyle Railway. The old engine was found by Mr. Alexander Allan when he was locomotive superintendent of the Scottish Central Railway about 1855, and before it was broken up it was photographed.

Next we come to the radial axle-box as used by Mr. Webb, Mr. Worsdell, and others. This was invented without doubt by the late Mr. William Bridges Adams, and was applied by Mr. Cross, on the St. Helen's Railway, in an exactly similar way to what Mr. Webb and others are now doing. The engine was called the "White Raven," and was on eight wheels, like Mr. Webb's, the two end pairs of small wheels being free to move radially. I need not say it was by no means so perfect as it has been made at Crewe and copied by others. The fact of the modern engine having inside bearings has greatly facilitated improvement and the making of a compact and useful design.

The position of the frames has passed through many changes, beginning with inside and then to outside, and then backwards and forwards from one plan to the other; until at last it has become almost universal that they should be inside, although in his last design of single engine Mr. S. W. Johnson has once more come to the outside and inside frame combined, as was for so long generally adopted. This double frame has undoubtedly the merit of enabling less weight to be carried by each square inch of bearing surface of the journals.

In 1851 Mr. McConnell put on the London and North Western Railway a class of engine called "Bloomers," which is without doubt exactly similar in general design to those made by Mr. Stroudley and known as the "Grosvenor" class, the only difference being that the latter designer was not hampered as Mr. McConnell had been by the necessity for keeping down the weight. Some of these engines are still, after thirty years, doing useful duty on the North Western Railway.

The battle of the gauges brought to the front various types of engines. Every engine builder and locomotive superintendent made the greatest possible efforts to *do something*, and sometimes with conspicuous success. In 1851 Mr. D. Gooch produced his "Lord of the Isles"; and this class of engine may be regarded as one of the most successful, for it continues to this day in its original form down to the minutest detail, and now working all the broad-gauge expresses between London and Bristol. New boilers these engines have had, and a higher pressure of steam has been the only change. The express is run now, though of much greater weight than in 1846, at *precisely* the same speed—namely, 53¼ miles per hour between London and Swindon. Stephenson & Co. also came to the fore with long boiler type and outside cylinders; the drivers of the single engine being placed in front of the fire-box, and two pairs of carrying wheels leading. Mr. Crampton, too, added his contribution in the shape of the "London" and "Liverpool," both of them with the driving wheels behind the fire-box and the carrying wheels in *front*, and with outside cylinders placed about midway along the barrel of the boiler. This class of engine was largely used on the Western of France and the Northern of France, and some survive to-day. Mr. Francis Trevithick produced at Crewe the "Cornwall," with 8ft. single drivers, 18in. cylinders, and 24in. stroke. To keep the centre of gravity down the boiler was placed wholly under the driving axle, which plan necessitated that the axle of the trailing wheels should pass through the fire-box. It was not a good engine for steam, and about 1863 was supplied with a new boiler above the driving axle; and it is thus working at the present time. Mr. John Viret Gooch, too, had a special engine made for the London and South Western line, with outside cylinders and 7ft. drivers, which did useful work for years; but he was tied in weight by the lightness of the road. Sharp Stewart & Co. constructed engines of large power for those days, which went by the name of "Jenny Sharp." They had 16in. by 22in. cylinders, with 5ft. 6in. single drivers, and inside and outside frames, and were very successful engines. They were from the design of the late Mr. Charles Beyer. E. B. Wilson & Co., of Leeds, produced an engine which was called "Jenny Lind." Of this class many scores were built; they had 15in. by 20in. cylinders with 6ft. driving wheels. The drivers had inside bearings only, and the leading and trailing were 4ft. wheels with outside bearings. They were largely used in the north, and as far south as Rugby on the Midland. These engines were principally designed by the late Mr. James Fenton

The railway itself has undergone in the course of years a considerable alteration and improvement; but the change cannot be called so radical as in the engine. The rails of which the pioneer railway was made were of wrought iron, in about 15ft. lengths, and about 35lb. per lineal yard, carried on very small cast-iron chairs, which were secured either to stone blocks or to light sleepers of larch timber, many of them of half-round section. The rails were of fish-bellied type, and the ends were a sort of half lap, about 2in. long. They were secured in the chairs with a cast-iron ball, of about 1in. diameter, held in by a wrought-iron key about ¾in. square, which was bent to prevent its coming out. In a few years a parallel rail with a small bulb bottom was rolled. This soon gave way to a double-headed rail, which held its own for many years. The form called the bridge rail was then brought out, similar to the rail used on the Great Western for the broad gauge; and this, increased in weight, is still used. About thirty-five years ago a rail, which was to dispense to a great extent with sleepers, was designed by Mr. W. H. Barlow, but the road was hard and not lasting, and was soon discarded. Some of the Welsh railways, notably the Newport and Abergavenny, were laid with it, as was also the Birmingham and Derby. About the same time the Vignoles rail was produced, and a great deal of road was laid with it; but after some years it was practically given up in England, except for light branches and for contractors' use. Foreign nations and America took it up, however, and it is now almost the only rail used. By the perseverance of Mr. C. P. Sandberg, who came over here as the inspecting engineer of the Swedish and Norwegian Governments, it was re-designed in detail, until it has now reached a weight of 105lb. a yard. We in England have gone on increasing the weight of the rail to meet the greater weight of engine, and have added sleepers in proportion until 2ft. 6in. to 2ft. 8in. is now the distance from centre to centre; but some of our foreign neighbours, notably the Germans, are still a long way behind us, notwithstanding they have equalled us in the weight to be carried on a pair of wheels.

Wrought iron and steel are gradually replacing the old cast-iron arches throughout our country. The earliest wrought-iron bridges of long span were certainly not handsome, though strong: notably the Menai, the Chepstow, the Saltash, &c. But the latest and the greatest ever made in the world, across the Firth of Forth, by Sir John Fowler and Sir Benjamin Baker, is not only enormous in size, but, now it is finished, looks a graceful structure. The bridge of Mr. Barlow, to replace the ill-fated bridge across the Tay, is also a beautiful piece of mechanical engineering. The fall of the old bridge and its consequences point a moral to all future engineers, and it is this:—Do not let others ever cause you to deviate from true principles, or allow them to persuade you to let mere money be the guide as to strength in your work. If Sir Thomas Bouch had not been influenced by such means he would not have built the bridge he *did*, and his bridge would be across the Tay to-day, and he, in all probability, might have lived till now. While on the subject of bridges, I cannot help the remark that Brunel's bridge across the Thames at Maidenhead has always been admired by me as the most graceful I ever saw. The high-level bridge of Mr. T. E. Harrison, at Newcastle, must not be omitted from this record, for at the time it was erected it was ahead of everything, and still stands as good as ever.

The report of the Research Committee on Marine Engine Trials (Professor Kennedy, Chairman) on the "Trials of Three Steamers, 'Fusi Yama,' 'Colchester,' and 'Tartar,'" was then read. The "Fusi Yama" is an ordinary trading vessel, and her compound-expansion unjacketed engines do not present any points of interest. The "Colchester's" engines are of the compound twin-screw type, and were quite new at the time of the trial. The "Tartar" is an excellent modern cargo vessel fitted with high-class triple-expansion engines. During the trial there was hardly any cargo on board, and the engines were working considerably below full power. The results obtained from the "Tartar" caused a large amount of trouble to the Research Committee, and they probably consider that she well deserved her name. It will be noticed on looking at the table of results that the amount of feed-water evaporated per lb. of fuel was extraordinarily large. From an analysis of the chimney gases, and from temperature observations, it was found that this figure was too high, and Professor Kennedy therefore concluded that a large amount of water mixed with the steam had passed through the cylinders. The table of results is given on the opposite page, in which, it will be seen, the results of the former "Meteor" trial are included.

In the discussion which followed the reading of this report, Mr. E. H. Carbutt drew attention to a sentence in the report, in which it stated that during the trials the steam of the main boilers was used exclusively for supplying the engines, and that all the steam necessary for working the circulating pump, &c., was obtained from an adjacent donkey boiler. In his opinion, the circulation of the water in the condenser should be effected by steam from the main boiler, and not from another source. Otherwise the committee had done their work excellently, and their facts and figures were remarkably complete. The meeting was then adjourned until the following evening.

On the resumption of the proceedings on Friday, the 2nd inst., Professor Kennedy said he would like to give the results of a trial of a Thames steam tug which he had made a short time ago at the request of the owners. The tug was propelled by a screw, which was driven by a compound engine. The following table gives the leading particulars:—

Diameter of cylinders	19in. and 35in.
Boiler pressure	76lb.
Revolutions per minute	107
Indicated horse-power	222lb.
Consumption of coal per horse-power per hour	3·3lb.
Ditto in carbon value	2·7lb.
Consumption of feed-water per horse-power per hour	22lb.
Efficiency of boiler	60 per cent.

Mr. P. W. Willans said that the arranging of the results of the trial of several vessels side by side was an additional feature of interest in the present paper. As regards the extraordinary efficiency of the boiler of the "Tartar," it was his opinion that a great deal of the water was never converted into steam at all, but passed over as watery vapour. It was, however, astonishing that there had been no evidences of such an occurrence in the engines themselves. In a vertical engine there was greater tendency to condensation below the piston than above, and he wished that Professor Kennedy had shown indicator diagrams of the performances below the piston, and not mixed with those of the upper end. He then detailed some experiments which he had made with regard to the condensation of steam on the under side of the piston in vertical engines. In one particular engine the average steam pressure as indicated used at times to drop 25 per cent., and this he found was due to the accumulation of water at the bottom of the cylinder. In order to obviate this, he cut a circular groove round the inside of the lower cover near its circumference, and arranged a copper steam pipe in this groove. Directly water began to accumulate he blew a current of high-pressure steam through the copper pipe, and the water was then dispersed by conversion into steam. He further ascertained that there was no great tendency towards condensation in the steam itself, but directly some was turned into water then the condensation continued. This was discovered by passing a current of cold water through the copper pipe above mentioned, while the steam was quite free from moisture and there was no accumulation of water; quite five minutes elapsed before any change took place, but after once beginning, the condensation continued rapidly. Mr. Willans concluded by suggesting that, in future trials, calorimeter tests of the steam should be made.

Mr. Henry Davey wondered why the compound engines of the "Fusi Yama" were not jacketed, for, in his opinion, the addition of jackets would increase the efficiency quite 12½ per cent. He said that he would be glad of some further facts bearing on the effect of piston speed on the efficiency of the engine. In comparing the triple-expansion engines of the "Meteor" with a similar land engine that he was well acquainted with, he found that the efficiencies were precisely equal, although the piston speed of the former was 490ft. per minute and that of the latter 140ft. per minute. Mr. Davey then entered into the vexed question of engine efficiency, and remarked that a standard method of reckoning efficiency was greatly needed. In his opinion it was neither fair to engineers nor to the engines themselves to say that the efficiency was the ratio of heat actually utilised to the amount of heat in the fuel reckoned from absolute zero. One could not expect to obtain any more heat work out of a body after its temperature had fallen to the temperature of the surrounding atmosphere, and he thought, therefore, that the ordinary temperature of the air should be considered the datum line from which to calculate efficiencies. Mr. Davey also said that the fact of marine engines being less efficient than land engines was to be accounted for by the use of simple forms of slide valve and valve gear still adopted in marine engines.

Mr. Schoenheyder said that the publication of the report of the committee had been delayed for an unpardonable length of time. In days of continual improvement like the present the data of the performances of a particular engine were useless if they were published after the engine was obsolete. The method pursued by the committee of combining a hundred or more diagrams into a mean diagram was very unsatisfactory, and every one of those hundred should be given separately if any good purpose was to be served. In his opinion the Institution gained no benefit by these trials, and the only persons who were any better off were the owners and

Digitized by Google

designers of the vessels, for they had obtained a complete test of the machinery, and all for nothing.

Mr. Lavington E. Fletcher asked the committee if they would in future tests and tabulation of results give the "piston constant," in addition to the dimensions, speeds, and pressures, for with these items of information the capacity of the engine could be arrived at with the greatest ease.

Mr. Frederick Edwards said that it was under his supervision that the engines of the "Fusi Yama" had been overhauled and repaired before the trial. New piston springs were added, and these had not had time to settle down into working order at the time the trial was conducted. Since then an improvement had taken place, and the engines were afterwards capable of working with an increased horse-power. He also took part in all the three trials, and he said that during the trial of the "Tartar" there was absolutely no sign of the presence of water in the steam, nor was there any record of priming in the ship's log-book. Since the trial of the "Tartar" complete diagrams of the work done by the circulating and feed pumps had been taken, and the results thus obtained would be added to the report. The pressure in the feed pump was extremely high, and represented a large amount of work.

Mr. J. F. L. Crosland said that marine engines had hitherto been supposed to work at very high efficiencies with a consumption ranging from 1¼lb. to 2lb. of coal per i.h.p. per hour; this bubble was now burst by the facts tabulated in this report.

Mr. Stromeyer said that the method of weighing coals on board ship by means of a spring balance was a bad one on account of the oscillations caused by the motions of the ship; whenever he had to do any such thing he always used a steelyard. The committee should have measured the temperature and quantity of the discharge water, and also the amount of air present in the boiler. There were also many data concerning the performance of the fuel in the combustion chamber, tubes, and uptake which might have been given, for then the total loss of work in the boiler could be apportioned and the various causes of loss ascertained more exactly.

Mr. G. R. Bodmer pointed out that, according to the results contained in the report, the loss of heat by initial condensation was least in the least economical engine.

Mr. C. J. Wilson, who had throughout the trials made the analyses of the chimney gases, &c., then gave an account of the method pursued by him in conducting his tests. Extraordinary precautions were taken, and every possible source of error was watched most carefully. For instance, in choosing the samples of coal for analyses, a large amount of coal was crushed to a fine powder and thoroughly mixed; then two samples were taken out, and each analysed. If the two analyses did not agree exactly further tests were made until practically absolute accuracy was obtained.

Mr. Phillips thought that the presence of water in the steam of the "Tartar" was to be accounted for by the fact that the vessel was propelled without a cargo, and that the power exerted by boilers and engines was much below what they were designed for.

Mr. C. E. Cowper expressed the desire that engineers would settle on standard methods of calculating efficiencies, and of combining the diagrams of two and three cylinder engines.

Mr. David Joy said that it would afford more information if the hundred or so diagrams taken were not combined into a mean diagram but were given separately; for it was highly desirable that they should be able to see the best diagram and the worst diagram, and that the variation in the diagrams should be noted.

Mr. Watkins said that boilers and engines should work to their highest limit if a satisfactory efficiency is desired, and, therefore, in his opinion it would have been better to use only one boiler when driving the cargoless "Tartar."

Mr. Hudson desired to have more information as to the condensers used on board these vessels. If the rate of discharge and the temperature of the effluent water had been given, some idea could have been obtained as to the transmission of heat through the tubes. Condensers were almost always designed by rule of thumb, and if the committee could carry out a series of accurate observations as to their behaviour, it would be possible to design condensers in future on more scientific principles.

Mr. Young said that a method of ascertaining the amount of priming had occurred to him. If the feed-water and the water in the hot well were analysed, then the difference in the analyses would account for the amount of water which had passed through the engines If the feed-water used were absolutely pure, then some substance might be put into it which would not distil over along with the steam; the different constitutions of the feed-water and the water in the hot well would, after a time, indicate the occurrence of priming.

Mr. Robinson wished that the air pressure, if any, in the ashpits had been given, for then it could be ascertained whether there had been any forced draught or not.

Mr. W. Worby Beaumont quoted a passage in the report on the "Tartar" trial, to the effect that the jacket of the high-pressure cylinder was not used, but that during the trial a leak was discovered in the cock through which the steam could be admitted to this jacket. This leak allowed steam to enter the jacket, and this steam had a pressure varying from 0lb. to 50lb. per square inch. In the speaker's opinion, the presence of this steam was quite sufficient to cause a condensation of steam in the cylinder.

The President, in closing the discussion, disagreed with the views of Mr. Watkins as regards the advisability of using only one boiler when propelling the cargoless "Tartar," for the greater the heating surface the better in comparison with the work to be done. As regards the use of triple and quadruple expansion engines generally, he mentioned that the necessity of having an equal load on each crank seemed to be overlooked by most marine engineers. The effect of such a want of equality on a locomotive would be to throw it off the line and almost make it turn a somersault, and arguing by inference a large amount of power must be wasted in a marine engine in counteracting and withstanding these strains. If a reducing valve or some other throttling device were placed in the receivers between the cylinders, the work of each cylinder could be equalised, and the objectionable strains avoided. In concluding, he expressed his gratification at the highly useful results obtained by the committee, and congratulated Professor Kennedy on the remarkably businesslike manner in which the trials had been conducted.

MARINE ENGINE TRIALS.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 6th May, 1890.

Iron.—The great drop in prices in Germany has had a weakening effect on the French markets for iron. Here in Paris the merchants who a week ago talked loudly of 160s. a ton for bars and joists, and no concessions on that price, are now offering the former at 152s. and the latter at 156s. Business is a little more brisk, the demand for joists having increased within the last few days. From the provincial markets we hear of manufacturers maintaining their prices firmly in the face of the slackening demand. But what is not so widely proclaimed is the fact that everywhere the merchants are underselling the manufacturers. Correctly judged, the markets are weaker than they were a fortnight ago, and prices are evidently tending downward. In the Haute Marne business is slackening, and founders complain of lack of work. Some have been compelled to put their men on short time. There is still some life in the export trade. The declared value of the exports of iron of all sorts in the first quarter of the current year amounted to £350,560, against £110,880 in the corresponding portion of 1889.

Metals.—Languor is still the characteristic note of the metal market. The prices of copper are nominally maintained, except "best selected," which has receded a point; but as there is practically no business doing, the quotations have no significance. Fluctuations in the market for tin have left prices a point higher than they were a week ago; but the market is weak. Lead shows a slight improvement. Spelter continues its downward movement. Consumers restrict their purchases to the bare necessities of the moment.

The Panama Canal.—The report of the Panama Canal Inquiry Commission has been issued. The completion of the canal on the lock system is estimated to cost 485,000,000fr.; 20 per cent. should be added for unforeseen expenses, and 29 per cent. for management and interest, making a total of 900,000,000fr. The annual cost of management and maintenance is estimated at 10,000,000fr., and the net receipts for the first three or four years are estimated at 38,000,000fr., rising then to 50,000,000fr., and twelve years after the opening to 61,000,000fr. The material and preparations of the old company are reckoned as amounting to, at least, half of the 900,000,000fr. still necessary. The Commission, regretting that they cannot hold out a more favourable prospect, think the best solution would be a guarantee of interest by the maritime States. In 1879 the time of construction was reckoned at twelve years, and the cost at 1,000,000,000fr., but ten years have elapsed, and a larger sum has been already spent.

BERLIN, 5th May, 1890.

Iron.—The last week has been a period of perturbation in the iron markets. The announcement of reductions in prices in the Western provinces far beyond what was expected startled the whole industrial world, and, so far as the markets here and in the Breslau district are concerned, checked the current of business in iron. Consumers of Silesian iron will now wait the effect upon prices of the reductions in the Rhenish-Westphalian district. For some time to come, therefore, we may expect buyers to restrict their dealings to the bare necessities of the moment.

Coal.—The situation has greatly changed for coal within the last fortnight. The reaction has evidently set in, and we may expect considerably lower prices by the end of the first half-year. The markets of Upper Silesia, so active of late, have lost much of their animation. A sudden calm has overspread them, and a weak tendency of prices has manifested itself. The reason is that consumers have now filled their stores, and can afford to wait the course of events, and as the recent tendering for locomotive coal showed an altered state of things in the coal trade, they abstain from further dealings till the prospect has cleared itself somewhat The matter is felt to be one of immense importance to German industry in general.

Coal Production in 1890.—The official statistics of coal production in the Prussian territory in the first quarter of the current year have just appeared. As they are specially interesting in the present circumstances of European trade, I make the following extracts to show, first, the state of the coal industry in Germany, and second, its distribution over the country. The total production in the first three months amounted to 16,522,864 tons, against 15,756,913 tons in the corresponding portion of 1889, the number of hands employed being 228,065, against 210,195 last year. These quantities were derived from the various mining districts in the following proportions, the figures within parenthesis being those for 1889: Breslau, 5,276,918 (4,778,639) tons; Halle, 5,727 (5,959) tons; Clausthal, 153,500 (115,736) tons; Dortmund, 9,032,150 (8,756,225) tons; and Bonn, 2,054,561 (2,100,354) tons. The production of lignite in the same periods amounted to 3,798,424 (3,388,797) tons, the number of hands employed being 26,664 (24,715). Of these quantities the mining district of Breslau produced 140,593 (132,416) tons; that of Halle, 3,428,182 (3,061,160) tons; that of Clausthal, 68,443 (47,840) tons; and that of Bonn, 161,206 (147,381) tons.

Telegraph and Telephone Extension.—The telegraph and telephone construction industries will have a busy year in this country. For the extension of these lines of communication a sum of nearly eight million marks (£400,000) has been provided by the Government, to be spent in the course of the present fiscal year. The scheme includes the conversion of some important aërial into subterranean lines for greater security in case of war.

Railway Inventions.—The German Railway Managers' Association has decided to give prizes of the value of 30,000 marks, every four years, for important inventions and improvements interesting to railways. For inventions and improvements in the structural and mechanical departments the first prize is 7,500 marks, and there are second and third prizes of the respective value of 3,000 and 1,500 marks. Prizes of a like value are to be given for inventions and improvements in the rolling stock, and also in the management and working of railways and the collection of railway statistics. Finally, a prize of 3,000 marks, and two of 1,500 marks, are to be awarded for noteworthy books on railways.

German Railways.—The revenue of the German railways in the working year from the 1st of April, 1889, to the 31st March, 1890, advanced 100,000,000 marks, as compared with the preceding year. The increase was chiefly owing to the activity of trade. Its importance will be better appreciated when it is learned that the increase in the six great French railways in the Exhibition year was only a little more than 78,000,000fr., of which 65,000,000fr. may be put down as due to the Paris Exhibition. The hundred million marks (or 125,000,000fr.) increase in the German railway traffic, due to no extraordinary circumstance, may be regarded as a very brilliant sign of industrial development.

Packing for Stuffing Boxes.—A new metallic packing for stuffing boxes, made of plaited bronze wire, is being manufactured by Mr. G. Pickhardt, Bonn. It possesses the advantage of having complete steam and water tightness at the highest steam pressure; it does not become hard or burn; does not cut into the piston rod; and is unusually cheap. With a sharp chisel a piece is cut off the plait long enough to go completely round the rod and to allow of the ends being firmly riveted when the ring is fitted in. Before being cut the ends should be wound with wire, so that the plait may not come uncoiled. The number of rings thus formed is determined by the length of the stuffing box. Between the metal packing and the stuffing box cover, a ring of hemp, tallowed twine, or india-rubber, is fitted in, to permit of the longitudinal expansion of the metal packing in the stuffing box.

VIENNA, 5th May, 1890.

The Iron Market.—For a short time the strikes in the collieries had a depressing influence, and during the first days of last week there was no business done. Now that regular labour has recommenced, and the largest establishments are at work, the customary animation in the market has returned. Prices are unchanged, and there is a firm tendency. The Alpine Montan Company has declared a dividend of 7½ per cent., and the profit of last year's working amounted to 2,109,000fl.

The Coal Market.—There is no change to note in the coal market. The strikes in the Ostrau district have terminated, and, as the demand is very brisk, the old animation has returned. Judging from the results of some joint stock companies, the business done this year has been better than ever before. The Brüxer Kohlenbergbau-Gesellschaft is paying a dividend of 7 per cent. Until 1885 no dividend was paid, and since that time it has steadily increased from 2 to 3, 4, 5, and 6½ per cent. The Trifail Coal Company is paying 8½ per cent. As a result of the animated coal traffic the waggon companies obtained large orders, and the report for 1889 of one of them shows that the profit amounts to 232,000fl., a dividend of 8⅝ per cent. being paid.

BRUSSELS, 6th May, 1890.

The Iron Market.—The iron market is calm. The raw materials are far too dear for satisfactory business, and prices are practically ruled by those of foreign iron. It is no use to reduce the prices any further, and if the prices of the iron syndicate are not accepted business will have to be refused. The rolling mills have not sufficient orders to keep them going continually. There is no great demand for sheets, and the prices of girders are low. The steel works are, however, much better off for work, and they seem to experience no great difficulty in obtaining orders at satisfactory prices. Several blast furnaces have been blown out, and some of the puddling furnaces also. The price of merchant bars is 18fr., and that of sheets 22fr.

The Coal Market.—In most of the branches of the coal trade there is plenty of firmness, but the prices of coke although high, show some signs of weakness. It is thought that coal prices are now about as high as they can be, and there is not so much confidence among sellers as regards the future course of the trade. Any new increase in the prices would stop the consumption to a considerable extent, as the industries in which coal is a raw material are even now almost paralysed by its high price. Coke is now quoted at 32fr. instead of 35fr., this reduction being caused by German competition.

The Glass Trade.—The state of the window glass trade is far from satisfactory. Orders are by no means sufficient to carry off the large production, and the prices have been consequently lowered to a disastrous extent in order that some of the surplus stock may be got rid of. It is impossible for the present state of things to last long, for it is utterly contrary to all common sense. In face of the poor demand, the number of glass furnaces are being increased, and probably many makers will come near their ruin shortly.

Electrical Engineering.—The electric tramway, which was started as an experiment in Brussels a short time ago, has been discontinued. The cars were propelled by accumulators, but the road was hilly and the route so objectionable, that the discontinuance of the system does not reflect any discredit on electric propulsion.

DÜSSELDORF, 6th May, 1890.

Iron.—Last week has been a period of considerable excitement in the iron markets. It was expected that the several syndicates would, at their next meeting, make some reduction in the minimum prices, but no one expected so large a drop as that which was announced a few days ago. The Rhenish-Westphalian Pig Iron Association reduced forge pig 12s., foundry 11s., Bessemer 11s., and Thomas pig 10s. a ton. Next the Rhenish-Westphalian Bar Iron Association announced a reduction of 20s. a ton for bars; and, to heighten the surprise, the West Germany Plate Iron Association followed promptly with a reduction of 20s. a ton for boiler plates and 35s. a ton for common plates. What the effect on the trade will be remains to be seen. For the moment business is very quiet. The following are the prices now current, compared with those paid a fortnight ago:—Rhenish-Westphalian best forge, 78s. (90s.); foundry No. 1, 82s. (93s.); Bessemer pig, 82s. (93s.); Thomas pig, 68s. (78s.) a ton. Bars, 180s. (200s.); boiler plates, 240s. (260s.); and common plates, 200s. (235s.) a ton. The South Germany Rolled Iron Association has been prolonged for three years. The coke syndicate has also been prolonged for three years, a circumstance that has tended to steady the iron markets.

Westphalian Coal at Hamburg.—The trade in Westphalian coal with Hamburg and its neighbourhood was not marked by greater activity in the month of April than in the previous month. It compares favourably, however, with that of April of last year, the total consignments being 67,150 tons, against 62,000 tons in the corresponding period of 1889. English coal is now being offered at slightly lower rates. It is expected that the prices of Westphalian coal will be considerably reduced before the end of the current month.

Roburite.—At the general meeting of the Actiengesellschaft Chemische Fabriken (formerly Weiler & Co.), held the other day at Cologne, it was resolved to increase the capital by 125,000 marks, for the purpose of buying up the Rhenish-Westphalia Roburite Company at Witten. The latter company will receive half the net profits in 1890. The purchasers take over the book debts for the sum of 44,456 marks. The manager of the roburite works stated that the business done last year was 50 per cent. greater than that of 1888, and that, according to present appearances, 1890 will show the same increase on 1889.

LILLE, 6th May, 1890.

Iron.—Judging from the general aspect of the iron market prices have a hardening tendency. Manufacturers refuse to sell bars or joists below 156s., and even talk of demanding 160s. before long, but as the middlemen are offering the same classes of iron at 154s. and less, it must be inferred that the real tendency of the market is downward. This is the opinion of consumers, who delay the placing of fresh orders till the latest possible date. The obvious truth is that business is languid, and that production is in excess of consumption. As soon as the contracts in hand have been worked off this fact will make itself felt. Hence we may infer that prices are giving way.

Textile Manufactures.—The trade in linen goods continues to shrink as usual at this time of the year, but the business done is fully up to the average. The May Day holiday and the strikes that have followed have now brought business to a standstill. The same remark applies to the woollen trade of Roubaix, where for the moment the utmost confusion prevails. A letter from Calais describes the tulle industry as lifeless, and the immediate prospect as gloomy. The disappointment has been bitter, for a year ago there were indications of returning prosperity, and hope rose high.

Flax and Yarns.—The flax market continues animated, if we except the last two or three days, in which trade has been influenced adversely by the labour disturbances which have occurred in this locality. For home-grown there is a brisk demand at full prices. Russian has been a little less inquired for. Prices are, however, very firm. There is an average market for tows; the better sorts being in brisker demand. Yarns are freely dealt in, and prices are firmly maintained. Jute spinners have no difficulty in getting rid of their produce.

Labour Disturbances.—To show the character of the labour disturbances which have brought the woollen industry of the Roubaix-Tourcoing district to a standstill, their origin and development may be described. A band of some 200 May Day holiday-keepers, who had kept up their carousing till the early hours of the morning near the Belgian frontier, were returning to Roubaix at the hour when their more sober comrades were going to their work. As a kind of practical joke, they compelled the latter to join them, and as they approached the town the numbers grew till the procession assumed an imposing magnitude The result was to stop work at all the factories, and, the Socialists

Digitized by Google

having turned the opportunity to the best account, a general strike was brought about. There are now about 100,000 out, and it is said that of these some 95,000 are kept out against their will by the remaining 5,000 riotous Socialists. A movement originating in such a manner has but little industrial significance.

AMSTERDAM, 5th May, 1890.

Railways.—The opposition to the Government proposals for the State acquisition of the Dutch-Rhenish Railway Company increases. The Ministerial Bill will probably be lost. At an extraordinary meeting of the shareholders, which sanctioned the proposed extension of time in the contract between the Government and the company, the Chairman said the latter had not been at all anxious to sell its properties to the former, but they had been compelled to do so. The company would gladly resume its existence under a new concession. The new cheap goods tariff between Holland and Germany, in competition with Belgium, was put in force on the 1st inst.

Dutch Railway in the Transvaal.—It is expected that the first section of the Dutch railway in the Transvaal (75 kilometres) will be completed and opened in the course of this year. The same company—the Dutch South African Railway Company—is building the steam tramway between Johannesburg and Boksburg, a distance of 50 kilometres, with the two extensions between the points named.

Mails to the Dutch East Indies.—The negotiations between the Government and the directors of the Nederland Steam Navigation Company, anent a more rapid and frequent conveyance of mails to and from Holland and Insuland, are nearly complete. The perfection of the new postal contract will necessitate the acquisition of more powerful steamers than the company at present possesses. From the report of the directors of the Rotterdam "Lloyd," which likewise has a mail service with the Dutch East Indies, it appears that the company performed twenty-two journeys in 1889, yielding a net profit of 815,000 guilders, and leaving an available balance of 380,000 guilders, after providing for reserve and writing off for depreciation. This enables the directors to distribute a dividend of 9½ per cent. on the share capital. In order to strengthen the fleet two new-type steamers are upon the stocks at the "Scheldt" shipbuilding yard, Flushing. One will be ready for service by the end of this year and the other by May next year.

COPENHAGEN, 3rd May, 1890.

Tramways at Christiania.—The Christiania Tramway Company has declared a dividend for last year of 7 per cent. At the general meeting the other day important extensions were discussed, entailing an outlay of some 250,000kr., and the board was authorised to negotiate with the Corporation with a view of making the necessary arrangements.

The New Gasworks at Stockholm.—The works at the new gasworks, which the Corporation of Stockholm has decided upon building, are already fully designed. The complete plan comprises four gas revervoirs, of which one, with the requisite buildings, is in course of erection. The buildings are of considerable dimensions; the coal-house will be 135 metres long and the retort-house 110 metres.

Petroleum at Copenhagen.—The Danish Petroleum Company at Copenhagen is extending its business. Last year a reception reservoir was constructed at Triborg, to the north of Copenhagen; and now another is approaching completion on the Refshale Island, in the Copenhagen harbour. The tanks, of which there are two, are protected by a wall of concrete and clay; there is room enough for a third tank, which will be added when required. From the tanks large pipes go to the quay where the vessels will discharge. A large tank steamer has been built for the company at Burmeister & Wain's shipbuilding yard, Copenhagen.

Engineering Societies in Sweden.—There are only two engineering societies in Sweden and these are about to be united. The older one—the Society of Engineers—was constituted about thirty years ago by practising engineers, in Stockholm, and the other—the Technological Society—was originally an association of fellows of the technical high school in Stockholm, but recently was transformed into a general society of technical engineers. The younger one is the most active of the two, and the meetings of the elder society have of late attracted very little attention.

Electrical Engineering in Sweden.—The Electrical Company, Ld., in Stockholm, the only dynamo manufacturing concern of any note in Sweden, recently held its meeting. The company was formed in 1883 to build dynamos of the Wenström type. Each year has shown an increase in the business, and last year the business amounted to about 330,000kr.; 38 dynamos were sold, giving a total of 501 electrical horse-power, and the installation of 4,234 incandescent lamps of 16 candles and 16 arc lamps had been completed. From the commencement the company has supplied 155 dynamos of 1,880 electrical horse-power, 17,400 incandescent lamps of 16 candles, and 35 arc lamps. A dividend of 5 per cent. was declared.

Swedish State Telegraphs.—The telegraphs have always been separate from the postal department, and have been under a special administration. At several times the question has been raised as to how to unite these allied departments under the same control, though until recently nothing positive has been done to realise this object. Some time ago the Government appointed a commission to investigate the matter and to propose means for its solution, and this time there is every reason to believe that within a short period this union will be an accomplished fact.

Telephones in Sweden.—Last year the first of the telephone trunk lines, that between Stockholm and Gothenburg, was opened to the public, and at present several others are under construction; for instance, one between Stockholm and Malmo, and one between Malmo and Gothenburg. These trunk lines are all metallic circuits without connection to the earth, and consist of hard-drawn copper wire. Between Stockholm and Gothenburg there are double telephone wires fixed on the same poles as the telegraph wires. One line is continuous between Stockholm and Gothenburg, and the other is connected at three or four cities with switchboards for the convenience of the public in those cities.

MADRID, 5th May, 1890.

Secondary Railways.—The Secondary Railway Bill pending at the Cortes has been altered slightly by the appointed Commission. In the first place, the interest guaranteed by the estate is to be 6 per cent. instead of the 5 per cent. per annum proposed, and, secondly, all materials and plant are to be Spanish, and if any foreign material is imported it will have to pay full duty. If the alteration of the Bill is carried through there will be no question as to the absolute necessity of establishing some very large and perfect works in Spain for making locomotives and carriages. Some influential parties in Bilbao are already contemplating the starting of such works in combination with English firms.

Spanish Quicksilver.—As is usual, the Almaden Quicksilver Works stopped the distillation of the ores on the 1st of May, and the hot months of the year will be devoted to repairs and putting things in order for the commencement of the season in October. This is principally done for the sake of general health, but also because most of the workmen find occupation in the harvest season of the year. The production of the mine during the past season has been rather under that of the previous one, on account of some mismanagement in the Madrid offices. Besides the Almaden mine, we have in regular production the quicksilver mine in Asturias, belonging to the Porvenir Company, which is continually increasing the output. Last year they obtained 1,955 flasks, Almaden giving about 52,500. However, the circumstances are so different that, whilst the average yield of Almaden is 6½ per cent., the yield of the Porvenir Company was only 1·07 per cent. So whilst the cost of each flask at the estate mine is about £1 12s., at Porvenir it is no less than £3 12s.

The Central Cuba Railways.—Tenders for the concession of this important system of railways were received by the Colonial Minister on the 26th ult. Two offers were made. Mr. Ivo Bosch, a Spanish banker at Paris, offers, on behalf of the Banco de Madrid, to take up the concession, with an interest of 8 per cent. to be guaranteed on a sum of £4,840,000. He, moreover, offers to the Government 55 per cent. of the net profits beyond the 8 per cent. The other proposal is from an English company, called the British and Foreign Constructive Company, Limited. The capital they propose is £4,893,000, and they offer the Government 75 per cent. of the net earnings exceeding 8 per cent. The other details of the conditions offered are very similar, but the fact that the Spanish tender engages to use Spanish materials for plant and railway rolling stock as far as possible makes it very likely that the final decision will be in its favour.

NEW YORK, 26th April, 1890.

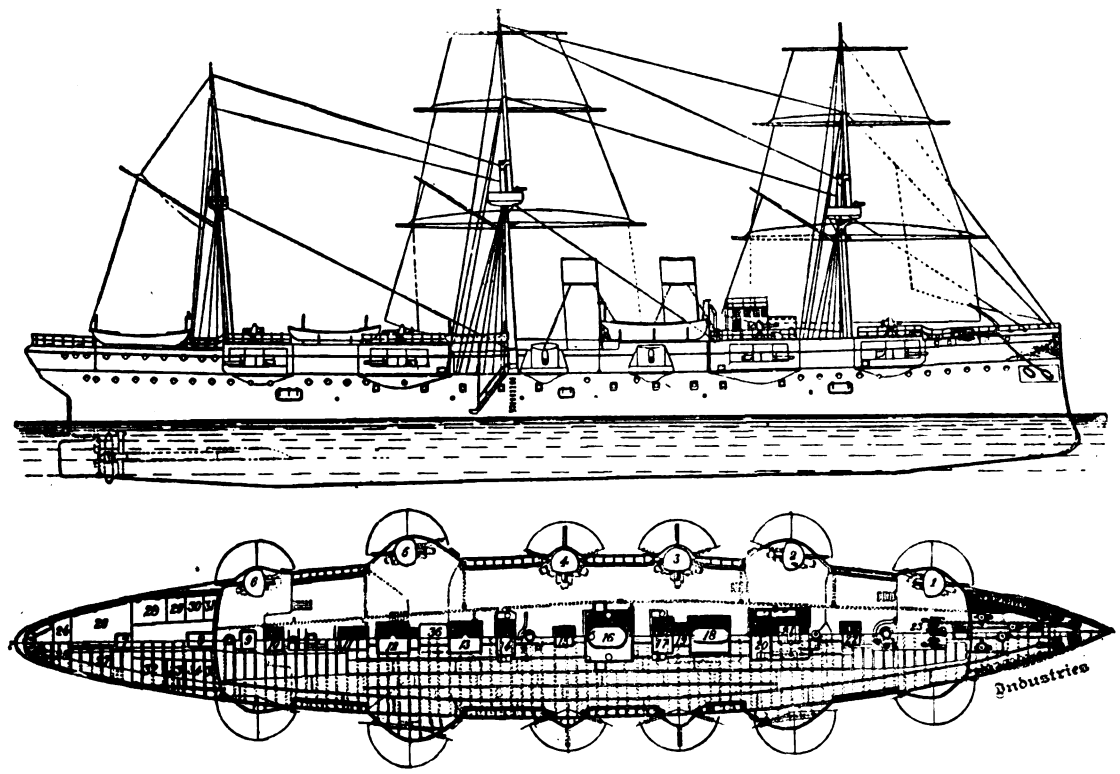
The Iron and Steel Market.—There is a steadier feeling in the iron trade, and although there has been no improvement in prices, and in some cases even lower quotations are reported, it is considered in the trade that the worst is over, and as soon as prices settle on the present basis the market will soon begin to improve. Prices of pig iron are at a standstill. Small lots of standard quality have sold at $18 to $18·50 per ton for No. 1 foundry, $17 to $17·50 for No. 2, and $16 for grey forge, and these are likely to be fair average prices throughout the summer. The cost of production is very heavy. Ores are high and coke is dear, and there is no likelihood of their becoming cheaper. The outlook is not particularly good, therefore, for producers, but consumers have a chance of renewing contracts at low rates, with a probability that prices will increase somewhat as the season advances. The demand for finished iron is better than it has been for some weeks, but prices are a little lower. Prices have now fallen back to what they were eight months ago. The decline in pig iron, old material, and various kinds of steel has been such that wrought iron has declined in proportion. Mills are getting nearer to the end of their orders, and there is considerable competition for any new business offered. Prices for small lots are from 1·85c. to 1·9c. per lb. for best refined bars, 2·10c. for plates, and 2·20c. to 2·25c. for angles. The demand for steel rails is not very heavy, and while the usual quotation is $34 per ton at the mill, only small lots are taken at that rate. What demand there is is mostly from Western Roads, and Western prices are something lower proportionally than at Eastern mills. Billets remain nominally at $31 per ton, but on desirable orders ·50c. to $1 per ton less could easily be obtained.

The Coal Trade.—There has been more activity in the anthracite trade during the past week than for some time. The opening of canal and lake navigation, and particularly the settlement of the question of tolls for the summer, have been the means of improving the trade. A great many dealers had been withholding their orders in hopes that the tolls would be reduced, and they placed them as soon as the question was settled. Prices are about the same, but they are rather steadier. If the present restriction of output is maintained, the trade of the latter part of the year will be fairly prosperous.

Gas for New York.—The Gas Commissioners met at the Mayor's office the other day, and resolved to postpone indefinitely the consideration of the tenders of the electric lighting companies for lighting the streets. It was learned that these companies had divided up the city, and each had confined its tender to the district allotted to it, thus preventing competition. The bid of the Equitable Gas Company for furnishing over 3,000 lamps with gas at $12 a year for each lamp was accepted. The Standard Company put in no bid, as its franchise does not allow it to charge over $12·50 per lamp. It was resolved to take steps to compel the company to furnish the Commission with a record of its mains, and to light such lamps on their lines as are not already contracted for with the other company. The Commissioner of Public Works said that last year the average paid for twelve months' service of each arc light used for street lighting was $24, and this year the tenders for lighting the streets by electricity have increased to an average of from $39 to $42 per lamp.

Fast Train Running.—A fast run on the New York Central and Hudson River Railroad occurred between Albany and Poughkeepsie, N.Y., on the 12th inst. The train was composed of an engine, a Michigan Central baggage car, one buffet car, one dining car, two passenger cars, one drawing-room car, and two sleeping cars. On the way over the bridge at Albany the cylinder head of the engine was blown out, and delayed the train at East Albany a little over 40 minutes, till another engine could be procured. At 5.34 p.m. the train started again. It ran from East Albany to Hudson (28 miles) in 30 minutes, arriving there at 6.5 p.m., and left at 6.10 p.m. It passed Tivoli (49 miles) at 6.29 p.m., Barrytown, at 6.33 p.m., Rhinebeck (54 miles), 6.40 p.m., and reached Poughkeepsie at 6.55 p.m., thus making the 70 miles with 8 cars in 1 hour 20 minutes, having run from Rhinebeck to Poughkeepsie (16 miles) in 15 minutes.

The Hudson River Tunnel.—The new shield is now being erected on the west side at a point 2,050ft. from the shore end. This shield is complete up to the top-girder, and will be in working order shortly. On the east side the condition is not so favourable. The late attempt to pump the tunnel out developed several very large leaks in the caisson next to the shaft; the shaft itself was badly shaken, and the timbers had separated so as to cause extensive leaks. These leaks have now been plugged in the shaft; but those in the roof of the caisson are more troublesome, as this is under the wharf. Divers are now at work trying to plug them up from below. It is hardly necessary to state that the late stories of "rats with oakum tied to their tails" being chased into the cracks in an attempt to plug them, are the results of the imagination on the part of the daily papers.



PHILADELPHIA, 25th April, 1890.

The Output of Iron and Steel in Allegheny.—The amount of finished iron and steel turned out in Allegheny, County Pennsylvania, in the first three months of this year was 455,000 tons. Of this a little more than 150,000 tons was iron from muck bar, of which probably 10,000 tons was bought from outside firms and finished there. The output of steel rails at Carnegie's Edgar Thompson Works was about 75,000 tons, which is more than was ever before made in the history of the plant. About 60,000 tons were made at the Allegheny Bessemer Steel Works, Du Quesne, making 135,000 tons of rails in the Pittsburg district. While a small portion of pig iron has been shipped from the south, there have been no foreign metal shipments so far this year. Nearly every ton bought was from furnaces in Pennsylvania and Ohio. Of this volume of iron and steel, which will be far over 500,000 tons at the end of April, there is not 500 tons in stock.

Philadelphian Carpet Trade.—The proposals of the new tariff to increase the duty on carpet wools has caused something of a consternation among the carpet men. During the year 1889 it is estimated that there were 8,000 looms in operation in this city, employing 17,000 operatives, and turning out upwards of 70,000,000 yards of carpet, valued at from $33,000,000 to $40,000,000, per year. The trade is in a flourishing condition, there being 180 distinct carpet mills in the city. Within the past ten years the industry has increased 60 per cent., and it is feared that the proposed increased duty on wools will raise the cost of carpets, which now average about 60c. per yard, to something over 80c., that the demand will become much smaller, and the trade lose much of its increase. The manufacturers were slow in waking up to the situation, but they are determined to continue their agitation, when it comes up for debate, against the adoption of the clause of the Bill affecting their interests.

THE UNITED STATES CRUISER "NEWARK."

THE UNITED STATES CRUISER "NEWARK."

On the 19th of March the 4,000 ton United States steel cruiser "Newark" was launched from Messrs. William Cramp & Sons' yard, Philadelphia. Especial interest attaches to the "Newark," from the fact that she is essentially an American ship in design, material, and construction, whereas several of the other new cruisers have been largely built after plans furnished by European engineers, and are, to some extent, copies of existing vessels in the English Navy, although with material modifications. The "Newark" is a twin-screw unarmoured vessel, having a poop and forecastle deck, with an open gun deck between. She is built of mild steel throughout, and has a steel deck extending her whole length, below which are the engines, boilers, shell-room, torpedo spaces, and steering gear. The engines and boilers are further protected by coal bunkers, which serve as extra armour as well as fuel stores. The engines are designed, with natural draught, to indicate 6,000 h.p., and with forced draught 8,500 h.p., and to give a maximum speed of 18 knots per hour. The following are the principal dimensions of the vessel:—

Length over all	328ft.
Length on the load water line	310ft.
Moulded breadth	49ft.
Extreme breadth	49·14ft.
Depth (knee plates to spar deck)	31·80ft.
Mean draught of water	18·825ft.
Displacement in tons to load water line	4,082·98ft.
Tons per inch at load water line	24·96ft.
Area of load water plane	10,484 sq. ft.
Area of immersed mid-ship section	807·23 sq. ft.

The "Newark" has a double bottom for 127ft., covering the space occupied by the engines and boilers, the depth between the inner and outer skin plating being about 39in., and this space being divided into 12 water-tight compartments by means of solid floors and a vertical keel. The engine and boiler space is divided into 17 water-tight compartments, while the space between the engine and berth decks is divided into 72 water-tight compartments. On the berth deck are 7 water-tight compartments, and all the openings from this deck to the engine and boiler rooms are protected by cofferdams, while the scuttles, hatches, and store-rooms are water-tight. Below the gun deck, when all the water-tight doors are closed, there are 147 distinct compartments, and there are 85 such compartments when the doors are all open.

The protective deck, for 168ft. of its length, rises to 15in. above the load water line, while forward it slopes to 4ft. 6in. below the water line, to strengthen the stem, and abaft it slopes to 3ft. below the water line. The horizontal portion of this deck is about 2in. thick, which is increased to 3½in. over the steering gear, while the sides are about 3in. thick, the angle of inclination being designed to prevent a projectile from striking a straight blow upon it. Armour shutters and scuttles of the same thickness as the deck are fitted at all hatchways and openings, and these are also inclined to deflect projectiles. The coal armour belt is about 9ft. thick amidship, and 7ft. forward and aft.

The main battery of the "Newark" consists of ten 6in. breechloading rifles, each using a 100lb. shell with a powder charge of 50lb., the projectile being designed to pierce 13in. of iron at its muzzle velocity. The guns are mounted on central pivot carriages, with circular shields fitted to each to protect the gunners from the fire of machine guns. The two forward guns, one on each side, are trained from 70° abaft the beam to 95° forward, giving a cross fire of 5° degrees at 111ft. forward of the stem. The two after guns have nearly the same range of fire, and all of the battery on one side can be concentrated on an object not more than 30ft. away.

The secondary battery consists of four six-pounders, four Hotchkiss revolving cannon, and two short Gatlings, while there will be other Gatlings in the fore and aft tops. The vessel will also have six torpedo-launching tubes worked from the berth deck.

The boilers and machinery of the "Newark" are ready to be put in. The power is to be furnished by two triple expansion engines with cylinders of 34in., 48in., and 76in. diameter and 40in. stroke. There are four boilers, each 13ft. 6in. in diameter and 19ft. 6in. long, designed for a steam pressure of 160lb. per sq. in., and with a grate surface of 540 sq. ft. Sail is to be used only as an auxiliary for cruising purposes, but a spread of 11,932ft. of canvas is provided for. The incandescent system of electric lighting is to be adopted throughout the vessel, and electric search lights will also be supplied. The ventilation will be effected by the exhaust system. It will probably be autumn before this vessel will be furnished with her machinery and fittings and be ready for trial. She is intended for use as a flagship, and the space under her poop will be made into quarters for the admiral and captain. She will have a crew of about 300 men. For the above description and illustration we are indebted to our contemporary *The Scientific American*.

THE EDINBURGH EXHIBITION.

The International Exhibition of Electrical Engineering, General Inventions, and Industries, Edinburgh, 1890, or, as it must more shortly be called, the Edinburgh Exhibition, was opened by H.R.H. the Duke of Edinburgh, on Thursday, the 1st inst. After the formal opening, the Royal party were entertained to luncheon, and subsequently were conducted to the Grand Hall, where a programme of music was executed. Finally, the party made a tour of the principal courts. The weather was splendid for early spring in Scotland, the buildings were crowded, and altogether it was generally felt that the opening was most auspicious. Notwithstanding the recent succession of Exhibitions, there is much to attract the technical as well as the general visitor. It is altogether a miscellaneous exhibition, bright, varied, and attractive, with handsome buildings and an ample variety of amusements. Our Exhibition executive committees have in their eyes rather the amusement and entertainment of the crowds who go to be amused than the edification of the few who go to be instructed. There are many reasons for siding with fun instead of culture, and for apparently truckling to the tastes of the vulgar instead of adopting the standard that the educated mind aspires to; but as this question borders on the ethical, we need not pursue it here.

It must be said that there is nothing whatever to illustrate the progress of electrical science in America, and so far, at least, no illustration of (we quote the prospectus) "the mechanical arts exemplified in the completion of the Forth Bridge." There is not even a hydraulic riveter, nor a suggestion of the methods by which the bridge was constructed, unless the wooden cantilever bridge over which the covered way is carried may have some remote connection therewith. The Executive might, at least, have procured some large scale drawings of the erection, in order that the crowds which are expected to visit Edinburgh to view the bridge and the Exhibition may have some intelligent idea of how it was built.

The site, luckily secured by the Executive free of charge from the Caledonian Railway Company and the Edinburgh Merchant Company, is fifty acres in extent, with an available additicnal area of forty acres, and is admirably adapted for exhibition purposes. It is bounded by two lines of railway and by a canal, and is intersected by the Edinburgh Suburban Railway. It is two miles from the heart of the city, and is readily accessible by rail or tramway. Trains from Glasgow and elsewhere are run direct to the Exhibition stations, of which there are no fewer than three. The main building (for elevation of which see *Industries*, of the 25th ult.) is 700ft. long by 300ft. wide. The vestibule and concert hall form a transept, on one side of which is the space for foreign exhibits, and on the other side that for British manufactures. The style of the front is French Renaisssance, with suggestions from Byzantine; but the simplicity of both exterior and interior, and the almost total absence of meretricious ornamentation, too often seen at recent exhibitions, is a laudable departure from the usual method of carrying out these styles. A covered way, resting on a cantilever wooden bridge, connects the main building with the Machinery Hall. This hall is 680ft. in length, 150ft. in breadth, and is 40ft. high. The girder roof is trussed and braced, the span being 80ft. In the centre of the Machinery Hall is the main electrical plant, to be hereafter fully described, and illustrated on page 444. The space is ample, and the plant is seen to better advantage than has been the case at any previous exhibition. The engineering and electrical department is under the charge of Mr. W. A. Bryson, whose similar work at the former Edinburgh Exhibition, and at the Manchester and Glasgow Exhibitions, has given him extensive experience of large electrical installations. Behind the Machinery Hall there is the Railway Court, the French electrical annexe, both to be hereafter described, and the boiler-house. In the latter there is a battery of five boilers made by Messrs. Galloway, of Manchester. The combined capacity of the battery is 1,400 horse-power. The recreation ground is lighted by twenty-four arc lamps suspended on poles 25ft high. The track is one-third of a mile long. The cost of the Exhibition buildings has been £50,000, the preliminary expenses bringing up the total cost of the Exhibition to date to £70,000.

The Electrical Exhibits.—In such an Exhibition the electrical section is naturally the first to demand detailed description. It goes without saying that there is much here that has been seen before. Nevertheless there is perennial interest attaching to a well-finished dynamo and to a well-designed switchboard, commonplace and everyday matters though they be. The electrical plant for the supply of light for the grounds and for the greater part of the interior of the buildings is contained within a railed-off space in the centre of the Machinery Hall. The plan of this space is illustrated on page 444.

The largest installation is by the Anglo-American Brush Electrical Corporation. The plant set down by this firm consists of fifteen dynamos. Of these, thirteen are No. 8 machines, old type, each supplying current to thirty-five lamps, and two are No. 7 machines, each supplying light to fifteen lamps. There are two lengths of countershafting, and six machines run on each length, there being one spare machine. The shafting runs at a speed of 320 revolutions per minute. The motive power for the twelve No. 8 dynamos first mentioned is obtained from a magnificent set of engines by Messrs. Robey & Co., of

Digitized by Google

Lincoln. These will form the subject of a separate notice under the head of prime movers. The total number of lamps in the Brush installation is 366, 71 being in the grounds and 295 in the buildings. Each lamp is 2,000 candle-power. Rope gearing is used for the main drives, and the endless cotton belting for working the dynamos was made by the Lancashire Patent Belting and Hose Co., Manchester. The shafting was made by Messrs. Brown Brothers, Rosebank Works, Edinburgh. The pulleys on the countershaft are by Messrs. Howellson & Walker, of York. Staffa's solid lubricant is used on the dynamo bearings, with obvious advantage in point of cleanliness, and with, it is reported, satisfactory results as regards lubrication.

The grounds are lighted by lamps in groups of three, upon bracketed masts, forty-five in number, each 65ft. high. In the recreation grounds there are twenty-four lamps, suspended from brackets on 25ft. poles. The feeding-wires are placed inside the masts. The globes in the outside installation are clear, and those within the buildings are of obscured glass. The switchboard is of simple and effective design, loop switch handles being used, so that any machine can be connected to any circuit in the installation.

Next to the installation of the Brush Electrical Engineering Company the most extensive is that of Messrs. King, Brown, & Co., Edinburgh. Though the plant to be put down by this firm is not yet completely in place, we may give the leading particulars of it. The concert hall is supplied with light from eighty-one super-incandescent lamps, and the dining-rooms with twenty-five lamps of the same type. These lamps are supplied by the Woodside Electric Company, and are of 200 candle-power and upwards. They are worked with an e.m.f. of 100 volts. Each lamp is provided with a safety fuse. The length of wire used in this installation is $8\frac{1}{2}$ miles. In addition to this portion of the public lighting of the Exhibition, Messrs. King, Brown, & Co. supply current for some 800 or 900 16 candle-power lamps on exhibitors' stands, and also supply current for the motor which drives the model of the engines of the "Princesse Henriette," exhibited by Messrs. Denny & Co., of Dumbarton. The four dynamos employed are of the type shown by Messrs. King, Brown, & Co. at previous exhibitions, and actuated by engines of the Westinghouse type, designed and made by Messrs. Alley & Maclellan, of Glasgow. The engines are two in number, and are respectively 125 h.p. and 80 h.p. One of these engines is of novel design, being an adaptation of the triple-expansion principle to this class of engine. This interesting engine will form the subject of a subsequent notice. In the meantime a single Brush dynamo is employed as a temporary expedient. Subsequently, Messrs. King, Brown, & Co. will put down one of their own dynamos. In addition, the same firm has a separate exhibit, consisting of two slow-speed ship dynamos constructed to Admiralty specification. Only one of these is as yet in position. It is a single-magnet machine with a ribbon-wound drum armature insulated with silk. The speed is 300 revolutions per minute. It supplies 120 amperes at 100 volts. The engine is coupled direct to the shaft and is bolted to the same bed-plate as the dynamo. The cylinder being below the armature shaft and bolted direct to the bed-plate makes an exceedingly compact arrangement. A system of centrifugal lubrication has been employed. The second dynamo is a four-pole machine, with an armature of similar type to the above, and a compound engine arranged in the same manner as its fellow. The capacity of the second dynamo, with 120lb. steam pressure, is 700 16 candle-power incandescent lamps, and the speed is 320 revolutions per minute. Both of these dynamos have been designed with a special view to meet the Admiralty requirements for low temperature, and the armatures, besides having large conductivity, have ample surface ventilation.

Messrs. Woodhouse & Rawson supply light for the band-stand in the grounds. The current is obtained from an Elwell-Parker 100-unit alternator, with engine combined. Messrs. Ernest Scott & Co.'s exhibit consists of three engines and dynamos. First, a 15-unit compound-wound dynamo, 150 amperes, 105 volts, at 950 revolutions. Second, a compound-wound machine, coupled direct to a vertical high-speed engine, making a self-contained plant, suitable for ship lighting: capacity, 100 lights 16 candle-power. Third, a 10-unit alternator, "Tyne" pattern, by Mr. W. C. Mountain, 1,000 volts, and 1,200 revolutions. All three sets of plant are employed in lighting nearly the whole of the outbuildings, including refreshment bars, Venetian glass factory, kiosks, Cadbury's cocoa-house, &c. The motor driving Mr. Webb's model engine in the railway annexe is supplied with current from this plant, as also the lamps in all the carriages and saloons exhibited by the railway companies. This firm exhibit, among miscellaneous electrical exhibits, a quick release spring switch, and show in action on all their machines the gauze brush, which is now coming extensively into use. The engines used are respectively 5, 7, and 9 n.h.p.

Notices of Meetings.

SOCIETY OF ARTS.—Tuesday, May 13th, at 8 p.m. Paper to be read: "The Use of Alloys in Art Metal Work," by Professor W. C. Roberts-Austen, F.R.S. Wednesday, May 14th, at 8 p.m. Paper to be read: "Professor Elihu Thomson's Electro-Magnetic Induction Experiments," by Dr. J. A. Fleming, M.A.

CHEMICAL SOCIETY.—Thursday, May 15th, at 8 p.m. Papers to be read: "On Diethylphosphorous Acid," by Professor Thorpe, F.R.S., and Mr. Barker North; "The Ten Isomeric Dichloronaphthalenes" and "The Action of Chlorine on Naphthalene and Naphthalene Derivatives," by Professor Armstrong and Mr. W. P. Wynne; "A Third Naphthaquinone," by Professor Meldola and Mr. Frank Hughes.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Monday, May 12th, at 7.30 p.m. Adjourned discussion on Mr. Bergström's paper on "The Structural Strength, &c., of Cargo Steamers of Different Types;" discussion on Mr. Boyd's paper on "The Weight of Machinery in the Mercantile Marine."

THE INSTITUTION OF CIVIL ENGINEERS.—Ordinary Meeting, Tuesday, May 13th, at 8 p.m. Paper to be further discussed: "The Screw Propeller," by Mr. Syd. W. Barnaby, M.Inst.C.E. Paper to be read (time permitting): "The Keswick Water-Power Electric Light Station," by Messrs. W. P. J. Fawcus and E. W. Cowan, Assoc.M.Inst.C.E.

THE PHYSICAL SOCIETY.—May 16th. (1) "On Haygens' Gearing in Illustration of Electric Induction," by Lord Rayleigh; (2) "Dr. R. König's Researches on the Physical Basis of Music," by Mr. S. P. Thompson.

THE ROYAL INSTITUTION.—Friday, May 16th, at 9 p.m. Professor Raphael Meldola, F.R.S., on "The Photographic Image."

PRICES CURRENT, 7TH MAY, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: The improved tone of the copper market mentioned in our last has been well maintained during the past week. This is due principally to the limited quantity of spot G.M.B. bars available, and the improved demand for different descriptions of refined copper. The old stocks continue to be firmly held off the market, and the labour troubles in Chili are restricting production there and increasing the costs. During April stocks decreased about 1,800 tons, the total visible supply being returned May 1st, as 90,200 tons, against 92,000 April 1st. From figures before us, the stock in England of bars, furnace material, &c., appears to be 42,000 tons, which is considered about the ordinary regular average, the surplus being in French hands, and practically off the market. The rise in silver has improved the Indian demand, especially for yellow metal. Some good locomotive copper orders have also been placed. Chili bars have ranged, during the week, from £49 to £50 cash, to-day's quotations being £49 12s. 6d. to £50 cash. Manufactured is quoted £62 sheets, £65 bottoms, with more inquiry.

TIN: Values have fluctuated considerably during the week. The market during the past few days has shown a stronger tone, with fair demand for sharp cash foreign, and prices are about 5s. higher on the week.

LEAD: Reports received from various sources point to an early improvement in lead. There is a better demand and more inquiry, with indications that higher prices will rule shortly.

SPELTER is steadily advancing, owing to the Continental demand and the small stocks. It is likely to be much dearer.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—There is quite a want of animation about this branch of commerce. Caustic soda, after a slight spurt, is again lower. Bleaching powder is quiet, but prices are unchanged. There is a moderate inquiry for soda ash for early delivery, and also for soda crystals. Carbolic acids continue to droop. Picric acid also is slow of sale. Creosote, however, is in good demand, and benzoles rather firmer. Sulphate of ammonia very flat, and carbonate of ammonia is also somewhat lower. Sulphate of copper is active for May–June delivery.

HOME INDUSTRIES.

LONDON, 8th May, 1890.

THE MONEY MARKET.—Though money has been in good supply at easy rates a good deal of uncertainty has prevailed in the discount market. Continental rates of exchange continue very low, and gold is steadily leaving the outside market for Paris and Berlin. In consequence discount rates are inclined to harden. The stock markets have been active this week, the principal movements taking place in American railway securities. The Silver Bill is confidently expected to pass, and stocks have not reached the point which the expansion of the United States currency is thought to enable them to attain. Canadian railways have moved in sympathy with Americans, as well as in consideration of their hopeful prospects. The securities of the Mexican Railway have been rather irregular in spite of the increased exchange value of the dollar. Home railways have improved through the recovery in pig iron, and the tone of this market is firm. A good deal of movement has taken place in the passenger stocks; an important legal decision affecting the relations of the South Eastern and the London Chatham and Dover has given a fillip to these securities. The Underground Railway stocks have been adversely influenced by the success of the Bill for the construction of a central subway through London. Foreign stocks have been firm, notably Egyptians, and a favourable turn in the conversion negotiations have benefited them. Argentine securities have improved greatly on a sustained decline in the premium on gold at Buenos Ayres. Copper shares have been in favour at higher prices, and South African gold shares have been receiving a little attention again. In the miscellaneous market there has been little movement save in telegraph cable shares, which have improved, and in telephones, which have declined. The nitrate group has fluctuated irregularly.

COMPANIES.—The following companies have been registered since our last report: Richard Whittaker & Sons, Ld., with a capital of £100,000, to carry on the business of brewers; St. Asaph Iron, Lead, and Baryta Co., Ld., with a capital of £30,000; Hollybrook Brick Co., Ld., with a capital of £20,000; J. H. Hopkins & Sons, Ld., with a capital of £100,000, to carry on the business of tinplate and ironplate workers; The Gospel Oak Iron Co., Ld., with a capital of £150,000; North Wales United Mines, Ld., with a capital of £25,000; Atkinson's, Ld., with a capital of £140,000, to carry on the business of brewers, &c.; The Diamond Patent Fuel Co., Ld., with a capital of £460,000; The Electric Welding Co., Ld., with a capital of £460,000; The Castle Hill Coal Co., Ld., with a capital of £25,000, to carry on the business of coalmasters, &c., in New Zealand.

RAILWAY TRAFFIC.—The gross receipts of the 23 principal railways in the United Kingdom for the week ending the 27th of April, amounted, on 16,159¼ miles, to £1,332,587, and for the corresponding period of 1889, on 16,031 miles, to £1,336,093, an increase of 128¼ miles, or 0·8 per cent., and a decrease of £3,506, or 0·2 per cent. The week last year with which comparison is made included part of the Easter season.

THE SILK EXHIBITION.—The first Exhibition of the Silk Association of Great Britain and Ireland was opened on Tuesday, at 7, St. James's Square, S.W., the residence of Lord Egerton of Tatton.

THE INSTITUTION OF CIVIL ENGINEERS.—The annual dinner of the students of this Institution was held at the Holborn Restaurant on Friday evening last. There was a large attendance of students and guests. Sir John Coode, President of the Institution, was in the chair, and was supported by Mr. Berkley, Mr. Hayter, Mr. Giles, M.P., Mr. Preece, Sir Bradford Leslie, Professor Unwin, Mr. Spagnoletti, &c.

ELECTRIC LIGHTING.—The town of Fareham, Hampshire, is to have a public electric lighting station, which is to be opened on the 1st September. The installation is to be carried out by Messrs. Laing, Wharton, & Down, who will lay down one Thomson-Houston alternating dynamo for 1,000 incandescent lamps, and a 30-arc light machine. The actual street lighting consists of 20 arcs and 100 glow lamps, the reserve output being for private lights. The engine will be supplied by Messrs. Ruston, Proctor, and Co.

THE POLYTECHNIC.—The early morning classes in commercial subjects, which were commenced on the 21st ult., at the Polytechnic, Regent Street, have been very successful. In the arithmetic class 90 students entered; French, 168; shorthand, 115; book-keeping, 105; German, 74; typewriting, 16. Many of the students attend from long distances, and arrive at 7 o'clock. At the conclusion of their class they are enabled to get a good breakfast at a very cheap rate. The classes were started with the view of organising a thorough course of instruction in connection with the scheme proposed by the London Chamber of Commerce, and the successful results attained will encourage the committee to start classes in other important commercial subjects.

THE ROYAL MILITARY EXHIBITION.—Yesterday the Prince of Wales opened the Royal Military Exhibition. The site selected is in the grounds of Chelsea Hospital, and the main buildings, which are constructed of corrugated iron, form a large quadrilateral erection of irregular sides. In the centre are some well-laid-out grounds, with a band stand, while in the outer part are various attractions which can be summarised as sundries. The exhibits were mostly complete, and the electric lighting was all in order. The lighting contract has been undertaken by Messrs. Davey, Paxman, & Co., of Colchester, who have engaged Messrs. Laing, Wharton, & Down to supply the dynamos and accessories. The plant consists of four continuous-current Thomson-Houston dynamos able to supply current to thirty-five lamps of 10 amperes. Three dynamos will be in use, with one for reserve. These run at 850 revolutions. There are two alternators of the standard Thomson-Houston type running at 835 revolutions, with an output of 1,000 volts and 35 amperes. Special transformers allow of the pressure being reduced to 50 or 100 volts, as may be desired. There are five arc circuits and three alternating circuits. All the lighting of the grounds and most of the interior lighting is by arc lamps, of which there are a hundred. The glow lamps are used for the offices, refreshment rooms, and other subsidiary buildings, and vary in power. There are, for instance, 200, 100, 50, and 10 candle-power lamps, the total being equivalent to about 1,000 16 candle-power lamps. In the grounds the arc lamps are fixed to wrought-iron posts 32ft. high, the bases being of cast iron 6ft. 6in. in length. Motive power is supplied by two 40 nominal h.p. undertype engines of Messrs. Davey, Paxman, & Co.'s make.

RAILWAY ACCIDENTS.—The number of persons killed on railways in the United Kingdom during the year 1889 was 1,076, as against 905 in 1888; while the injured were 4,836 in number, against 3,826 in the year before. That is, the fatal injuries increased by 171, and others by 1,010. A great part of this vast increase is to be accounted for under one head. Fatal injuries to passengers arising from accidents to trains, rolling stock, permanent way, &c., had been reduced to 11 in 1888, and other injuries to 594. In 1889 the list of killed is eightfold, and of injured nearly twice as great. The numbers thus reached—88 killed, and 1,016 injured—are far above the average of recent years. The cause of a great part of the increase is not far to seek. The disastrous accident on the Great Northern Railway of Ireland (June 12th) caused the deaths of 78, and injuries to 200 passengers, many of whom, it will be remembered, were children. Passengers killed and injured from other causes remained almost stationary in numbers—95 and 813 respectively. The injuries to servants were also much above the year 1888, when the killed were 396 and injured 2,193. Last year these numbers rose to 435 and 2,769. Trespassers again (in which class are included suicides) shared in the general increase; the killed were 351 (56 more), and the injured 122 (six more). All accidents being taken together that occurred on railway premises, the total during the year 1889 amounted to 1,139 killed and 10,981 injured.

MANCHESTER, 8th May, 1890.

THE MUTUAL TELEPHONE COMPANY.—A company bearing this title is being formed, with a capital of £100,000, of which £45,000 is at present being issued. The dividend to be paid is limited to 6 per cent., after which all net profits are to be returned to the renters. The company proposes to commence work on the expiration of the Bell patents at the end of this year.

MANCHESTER BANKING.—As an instance of the rapidity with which banking has increased in Manchester, the following figures relating to the first three months in each of the years named may be given. During that period in 1879, the Manchester Clearing House dealt with £20,783,875, while this year the amount was £43,649,308, or more than double that of 1879. This shows the great strides made by Manchester as a financial centre, a fact which is also evidenced by the advance in the price of the shares of local banks.

SHRINKAGE OF COTTON YARNS.—The Manchester Chamber of Commerce recently met in conference with the Glasgow Chamber at Carlisle, to determine upon a basis of allowance for the shrinkage of cotton yarns during dyeing. Under the Indian Merchandise Marks Act of last year this has become a matter of importance to exporters. It was agreed to ask the Indian Government to sanction the importation of yarns with a reasonable allowance for shrinkage, but it was decided that the extreme allowance made should not exceed 2½ per cent. from the standard length of 840 yards per hank.

THE ENGINEERING TRADES.—There is a rather better tone existing among engineers in this district. Things are a little more cheerful, although the amount of new work is not great. There are signs of improvement, however, for the steadying of the prices of raw materials is having a good effect. Boiler makers are well employed, although there is not the pressure in this department that existed a short time since. Tool makers are generally well off, and there does not seem to be any lack of new business. In the railway department especially, orders for tools are being given freely. Spinning machinists are busy. The whole of the plant for the Elm Spinning Company, consisting of 70,000 spindles and preparation machines, is being made by Messrs. John M. Hetherington & Sons, of Manchester, who have recently greatly improved their mule. Ring spinning machine makers are also busy, and a new spindle of the "elastic" or "top" type is being put upon the market by Messrs. T. Coulthard & Co., of Preston. Loom makers are fairly busy, although plain looms are not so much in request.

IMPROVED RING BOBBINS.—An improved ring spinning bobbin is being introduced, the novelty of which consists in its being all made of wood, without the ordinary brass or steel hoop at the lower end. To strengthen the bobbin at that point a semicircular bead is formed just above the nose, fitting into the cup on the spindle. These bobbins have been severely tested, and we have seen several of them after the tests which have resisted compressive strains quite as well as the brass-hooped type. The cost being much lower than that of the latter, the new form has much to recommend it.

GLASGOW, 8th May, 1890.

PIG IRON.—In sympathy with the generally buoyant character of the stock markets, stimulated probably by the passing of the Silver Currency Bill, the pig iron market has been firm, with a large business doing at advancing prices, but the Cleveland makers' returns for the month of April being considered disappointing a reaction set in, and the market opened on Tuesday morning at a fall of about 1s. from the closing prices of the previous Friday.

FORTH BRIDGE.—The first through passenger train passed over the Forth Bridge on Monday. The train was a special excursion train from Aberdeen to Edinburgh *viâ* the Forth and Tay Bridges. The bridges on the Burntisland section will not, however, be ready for some time, so that the full use of the bridge will not be available till the summer has well progressed.

SHIPBUILDING AND ENGINEERING.—The local shipbuilding and engineering works now complain of a blank outlook. One of the leading Greenock shipbuilding yards launched its last ship this week, and other yards are working off the orders they have on hand very rapidly. Wages have been reduced at several of the steel works, and further reductions are not improbable. Notices have indeed been already given by several firms.

ENGINEERING.—The new pumping machinery which the Bonhill local authority had decided to provide for their pumping station at Balloch is now completely fitted up. Messrs. Joseph Evans & Sons, Wolverhampton, erected the machinery, which consists of one of their horizontal direct-acting compound surface-condensing duplex type, with two high-pressure cylinders, each 15in. diameter; also two low-pressure cylinders, each 24in. diameter and 3ft. stroke. The engines are guaranteed to deliver 60,000 gallons of water through a 12in. pipe, 2,500 yards long, to the reservoir at Alexandria, 170ft. high.

LABOUR.—The shipbuilders in Greenock have decided to grant an advance of a farthing per hour in response to a request of the joiners for a halfpenny. The workmen have agreed to accept the offer.

GOLD EXTRACTION.—An important improvement in the method of roasting refractory ores has been made by the Pollok Patent Gold Extracting Company. The machine is the invention of Mr. Alley, of Messrs. Alley & McLellan, who is of one the directors of the company. The roasting apparatus consists of a hollow cylinder, where the ore is heated while the cylinder revolves. The ore passes from the crushing mill into the roaster, and is subjected to heat, and is discharged from it ready to be introduced into the chlorinators. In connection with this company Mr. Pollok is about to proceed to the Transvaal, where works are to be erected by the company. The same company intend also to establish works at Taltal, Chili.

ELECTRICAL ENGINEERING.—Messrs. Mavor & Coulson have contracted with the British India Navigation Company for the lighting of the offices of the company at Calcutta. About 300 incandescent lamps will constitute the installation.

GLASGOW BILLS.—The Boundaries Bill has been thrown out. It will come up again in a new form. The Caledonian Vale of Leven Railway Bill has been thrown out. The Clyde Navigation Bill, which provides, amongst other things, for the diversion of Govan Road round the new Cessnock Dock, has passed the Committee stage, the preamble having been proved. The Railway Amalgamation Bills are still before the Committee. The preamble of the Subway Bill has been passed.

(From our own Correspondents.)

LIVERPOOL, 7th May, 1890.

THE SALT INDUSTRY.—There has been a considerable increase in the export of salt from Liverpool to the different foreign countries during the last month, amounting to 59,537 tons, against 48,536 tons during April last year. The shipments during the first five or six months last year were equal to the average, and as the shipments during the first three months of this year are in excess of those of last year the results are very reassuring.

NEW WELSH COAST STEAMBOAT SERVICE.—Considerable dissatisfaction has been felt for many years at the slow and inconvenient service of steamers running between Liverpool, Llandudno, and Carnarvon; and at the recent meeting of the shareholders of the Welsh Coast Steamboat Company it was proposed to purchase the fine steamer "Cobra," and run it in conjunction with the present boats, and so improve the service. Upon a vote being taken, 897 shareholders voted in favour of the proposal and 591 against it. Although there was a substantial majority in favour of the purchase, by the constitution of the company the majority was not sufficient to carry the proposal. Several of the leading directors of the company intend to resign their position, and are now pushing forward the new company. Arrangements have been made for the purchase of the "Cobra," and it will shortly be put upon the station.

DOCK ACCOMMODATION IN LIVERPOOL.—Great complaints are now being made by the shipowners about the depth of the water over the dock sills, and a strong letter of remonstrance has been addressed to the Dock Board by

Digitized by Google

Mr. T. H. Ismay, of the White Star Line. He states that while the Canada Dock has an entrance 100ft. wide, the depth of the sill is only 7ft. 9in.; the Alexandra Dock has an entrance 60ft. wide only, with a depth of 12ft.; while the Birkenhead Docks, built twenty-five years ago, have entrances 100ft. wide, with 12ft. sills. When the North Docks were commenced twelve years ago, the largest ship to be accommodated was 6,000 tons; but steamers of 10,000 tons, and nearly 600ft. long, have now to be provided for, and the tendency is for the size to still increase. The "Majestic" arrived on the 23rd ult., but was unable to cross the bar on account of insufficiency of water; the low tides also prevented her from using the docks, although she had to pay £308 for dock dues, in addition to the cost of landing her passengers in tugs.

LEEDS, 7th May, 1890.

The Iron and Steel Trades.—The improved tone indicated a fortnight ago has been maintained in the present month. Specifications are coming forward more freely, and all the forges are actively employed. A steady business is being done in cut steel and iron nails at recent rates. Nearly all the branches of the engineering trade are fully occupied, though there continues in some departments to be a marked absence of fresh inquiries and orders. Locomotive builders are well off for contracts, and some of the leading firms engaged in the manufacture of heavy machinery have not much cause of complaint on the score of work. The machine tool trade has undergone very little change. The Leeds Chamber of Commerce has had under consideration the circumstances that in the negotiations between the Associated Chambers of Commerce and the Board of Trade for considering what is best to be done with reference to terminating charges between England and France, no representative of the iron and steel trades of this district was suggested. The Chamber in Leeds has now sent up the name of Sir James Kitson to the Associated Chambers of Commerce and the Board of Trade, with the view of his being a member of the conference, which is said to be likely to do some important work in connection with the exportation of Yorkshire-made iron and machinery to France.

The Coal Trade.—Pits are running from five to six days per week. All classes of house coal are in fair demand, but there is a tendency to a reduction in prices. Gas coal is declining, while the steam coal trade remains brisk. Manufacturing fuel is more plentiful and prices easier. The shipping trade is brisk. There has of late been a great falling off in the demand for coke, and consequently a lowering of prices. Stocks are accumulating.

SHEFFIELD, 7th May, 1890.

Iron and Steel.—All kinds of railway material are in good request, and orders booked early in the year are not worked off yet. A large firm of spring manufacturers here are turning out 300 springs for waggon and carriage bearings every week to the order of one of the English railway companies. Axles are now made with a lower percentage than ever of carbon, the tensile tests being from 27 to 30 tons per square inch, with an elongation of 40 per cent. in 2in., and a reduction in area of 50 per cent. Prices generally have dropped considerably during the last month. Engineers continue busy, although there are more men out of employment than for some time past. The recent advance of 2s. per week in wages recently granted to mechanics is leading to a great deal of friction in some shops. The societies insist upon paying all men equal wages, quite irrespective of their qualifications as individuals. The standard rate of pay is now 36s. for 54 hours.

Additional Railway Accommodation.—The Manchester, Sheffield, and Lincolnshire Railway Company are again fortunate in their application to Parliament for powers for extension. The Select Committee have passed the preamble of a Bill for the substituted railway from Staveley to Chesterfield, and for a new line from Chesterfield to Heath, over which the London and North-Western Railway Company will have running powers.

NORTH STAFFORDSHIRE, 7th May, 1890.

The Iron Trade.—Matters are getting very serious for manufacturers. Owing to the fall in prices consumers are withholding specifications on account of contracts entered at high figures, and new orders are very scarce indeed. Some firms have not enough work on their books to carry them on for more than a few days. It is becoming quite customary for the mills and forges not to start till Tuesday night. Altogether manufacturers are in a worse plight than they were at the lowest stage of the recent depression. The increased cost of production is such that present prices are not of a remunerative character. Bars are selling at about 7s. 5d. per ton, and forge pig iron at 55s. Unless the retogressive movement in prices is shortly stopped some reduction in wages must be the result.

The Coal Trade.—There is a fair demand for coal for manufacturing purposes, and slack is in good request. Prices show some signs of weakness, more particularly in the case of house coals, but there is no actual reduction in current quotations.

The Pottery Trade.—Manufacturers are fairly busy, and orders on American account are being received. A disastrous fire occurred last week at the Imperial Pottery, Longton, recently purchased by Messrs. T. Forester & Sons. The damage is estimated at about £6,000.

CARDIFF, 7th May, 1890.

Iron and Steel.—The decision of the steel makers to reduce the price of steel tinplate bars has caused some dissatisfaction amongst tinplate makers, whose contention is that the heavy reduction is only nominal, and is a lever to their buyers to induce them to further reduce their quotations. Most of the steel makers are well sold forward, and consequently will not offer at the association price. Steel rails are inactive. The hematite pig iron trade is no worse; considering the recent reductions every week, this is somewhat satisfactory. Makers still have contracts to execute at high figures, so there is a reluctance to accept market prices when quotations for raw material are comparatively firm. In iron ore there is little new business to record; the contracts made at the beginning of the year are quite equal to the production of the miners on the one hand, and the wants of the works on the other. Rubio ore is quoted at 15s. 6d. c.i.f. Cardiff or Newport, 15s. 9d. Swansea, 16s. 3d. Briton Ferry and Porthcawl, 16s. 9d. Port Talbot.

Coal and Coke.—Steam coal is steady; the price for first quality is 14s. 6d. to 15s. 3d. f.o.b.; second, 13s. 6d. to 14s.; and third, 12s. 9d. to 13s. 3d. There is a disposition amongst colliery owners to form limited companies of their undertakings. The first announced is that of Messrs. D. Davis & Sons, Ferndale and Blaengawr collieries, whose output is near a million tons per annum. The coal has a first-class reputation in foreign markets. Other collieries are likely to follow. For coke there is only a moderate inquiry, the contemplated blowing out of furnaces acting as a deterrent to ironmasters from making new purchases.

BARROW-IN-FURNESS, 7th May, 1890.

Steel.—There are no new orders coming to hand for tinplate bars, and the mills are all stopped. This means a reduction in the output of steel of 1,000 tons a week. Other departments of the steel trade are quiet. There is considerable briskness industrially so far as rails, shipplates, and angles are concerned, but the demand is quiet.

Hematite Pig Iron.—The men employed by the West Cumberland Iron and Steel Works have demanded an increase in their wages in face of a declining market. The directors have refused to consider the overtures of the men, and they have closed their works until it is possible to produce iron and steel at a profit. Eight hundred men are thus thrown out of work. Already 400 men have been made idle in consequence of the damping down of furnaces at the works of the Moss Bay and the Lowther Companies. It is probable that there will not be a resuscitation of activity at Workington until the market prices leave a profit to the producer. At present hematite warrants are selling at 55s. 3d., while makers are quoting 60s. to 65s. per ton net f.o.b. for Bessemer pig iron in mixed parcels. In the meantime stocks are gradually being reduced. They now amount to 334,013 tons, being 46,629 tons less than in the beginning of the year. There are forty-seven furnaces blowing out of seventy-nine, and other furnaces are to be damped down shortly.

MIDDLESBROUGH, 7th May, 1890.

Pig Iron.—The pig iron market, after giving promise of a more cheerful tone, has relapsed into the same uncertain state. This condition is perplexing the minds of buyers, who, in the meantime, hold aloof. Yesterday the market opened with No. 3 G.M.B. being sold at 46s. for prompt f.o.b. delivery, but towards the close 45s. 6d. was all that could be got, and there was not much done at that. Some makers have come down to merchants' prices. Middlesbrough No. 3 warrants are down to 45s. 3d., buyers offering 45s. cash. West Coast hematites are quoted at 55s. 6d. to 55s. 7½d. cash, and East Coast hematites at 65s. per ton. Connal's stocks stood on Monday at 129,582 tons, being 3,320 tons less than a week ago.

Ironmasters' Returns.—The total make of all kinds of pig iron during the month of April amounted to 235,157 tons, as against 244,889 tons in March, being a decrease of 9,732 tons, with one day less in the month. On the 30th of April the stocks of pig iron amounted to 277,597 tons, as against 274,022 tons on the 31st of March, showing an increase of 3,575 tons. During the month of April the shipments abroad from the port of Middlesbrough amounted to 59,886 tons, against 43,697 tons during March and 64,623 tons during April, 1889. The shipments coastwise during April amounted to 16,420 tons, against 16,986 tons during March and 39,826 tons during April, 1889. These show a total decrease on April, 1889, of 28,143 tons.

Manufactured Iron and Steel.—Iron and steel are comparatively dull. Specifications are difficult to obtain, and some works have had to run short time. The Esson Steel Works have ceased work entirely for the present. Iron ship-plates are at £6 5s., but £6 2s. 6d. and even £6 would be taken; angles are at £6 2s. 6d.; bars, £6 5s. per ton. Steel ship-plates, £7 7s. 6d.; angles, £7 7s. 6d.; rails, £5 2s. 6d. to £5 per ton, all less 2½ per cent. on trucks at manufacturers' works.

SUNDERLAND, 7th May, 1890.

Shipbuilding.—The fall in the cost of iron and steel may be expected to lead to the placing of some contracts with shipbuilders, by firms who wish to replace tonnage, although no great influx of orders can be expected until there has also been a corresponding reduction in the cost of labour. One contract has been recently secured on this river—viz, by Mr. James Laing, Deptford, from Messrs. Ballard, King, & Co., London. The vessel is to be a duplicate of the s.s. "Umbolozi," which was recently lost. She will be fitted with triple-expansion engines by Messrs. George Clark & Co., Ld., Southwick Engine Works.

Shipping.—The principal feature of the freight market during the last ten days has been the large number of fixtures that have been made for autumn loading on the Black Sea and Danube. Prompt rates for the same trade are at present much improved, but early loading is not satisfactory. The feeling as regards the future is generally not so despondent, and a large demand for tonnage in the American trade later on is anticipated in some quarters. The Baltic outward freights have improved, but coasting and outwards to the Mediterranean still rule low The local import and export trade has been very brisk during the last week; fifteen vessels arrived, with cargoes of iron ore, iron, timber goods, &c. The coal shipments were above the average, amounting to 86,165 tons, a net increase compared with the previous week of 16,965 tons; 43,001 tons were shipped to foreign ports, an increase of 15,163 tons, and 42,964 tons to home ports, an increase of 3,602 tons. There were also shipped coastwise 1,010 tons of patent fuel, 120 tons of lime, 20 tons of cement and sundry other merchandise; and to foreign ports, 405 tons of coke, 25 tons of sanitary pipes, a case of machinery, two anchors and chains, &c.

NEWCASTLE, 7th May, 1890.

The Iron Trade.—The prices of finished iron have further declined, and are now fully £2 per ton below the highest point attained. In the pig iron trade a more cheerful tone is being manifested, and hopes that business will be steadier for the remainder of the year are generally entertained. The Gateshead Ironworks, which for more than a century were owned and worked by Messrs. Hawks, Crawshay, & Sons, are advertised to be sold by auction on the 13th inst.

Shipbuilding.—There was launched on Monday, at the Elswick shipyard of Sir W. Armstrong, Mitchell, & Co., an armed cruiser, which has been built to the order of the Argentine Government. Another vessel, of smaller dimensions, will shortly be ready for putting off the stocks at the same establishment. The yard of Messrs. Schlesinger, Davis, & Co., which is one of the largest on the river, having seven building berths, is now quite empty, the last vessel on the stocks having been launched a few days ago. This is the first time since 1886 that an important yard on the Tyne has been wholly tenantless. The Blyth Shipbuilding Company have just opened their new graving-dock, and are now in a position to undertake all kinds of repairs to both the hulls and machinery of vessels. The dimensions of the dock are:—Length, 350ft.; width at entrance, 55ft.; depth of water on sill in ordinary spring tides, 19ft. The dock can be emptied in a little over two hours by a set of powerful centrifugal pumps, supplied by Messrs. Drysdale, of Glasgow.

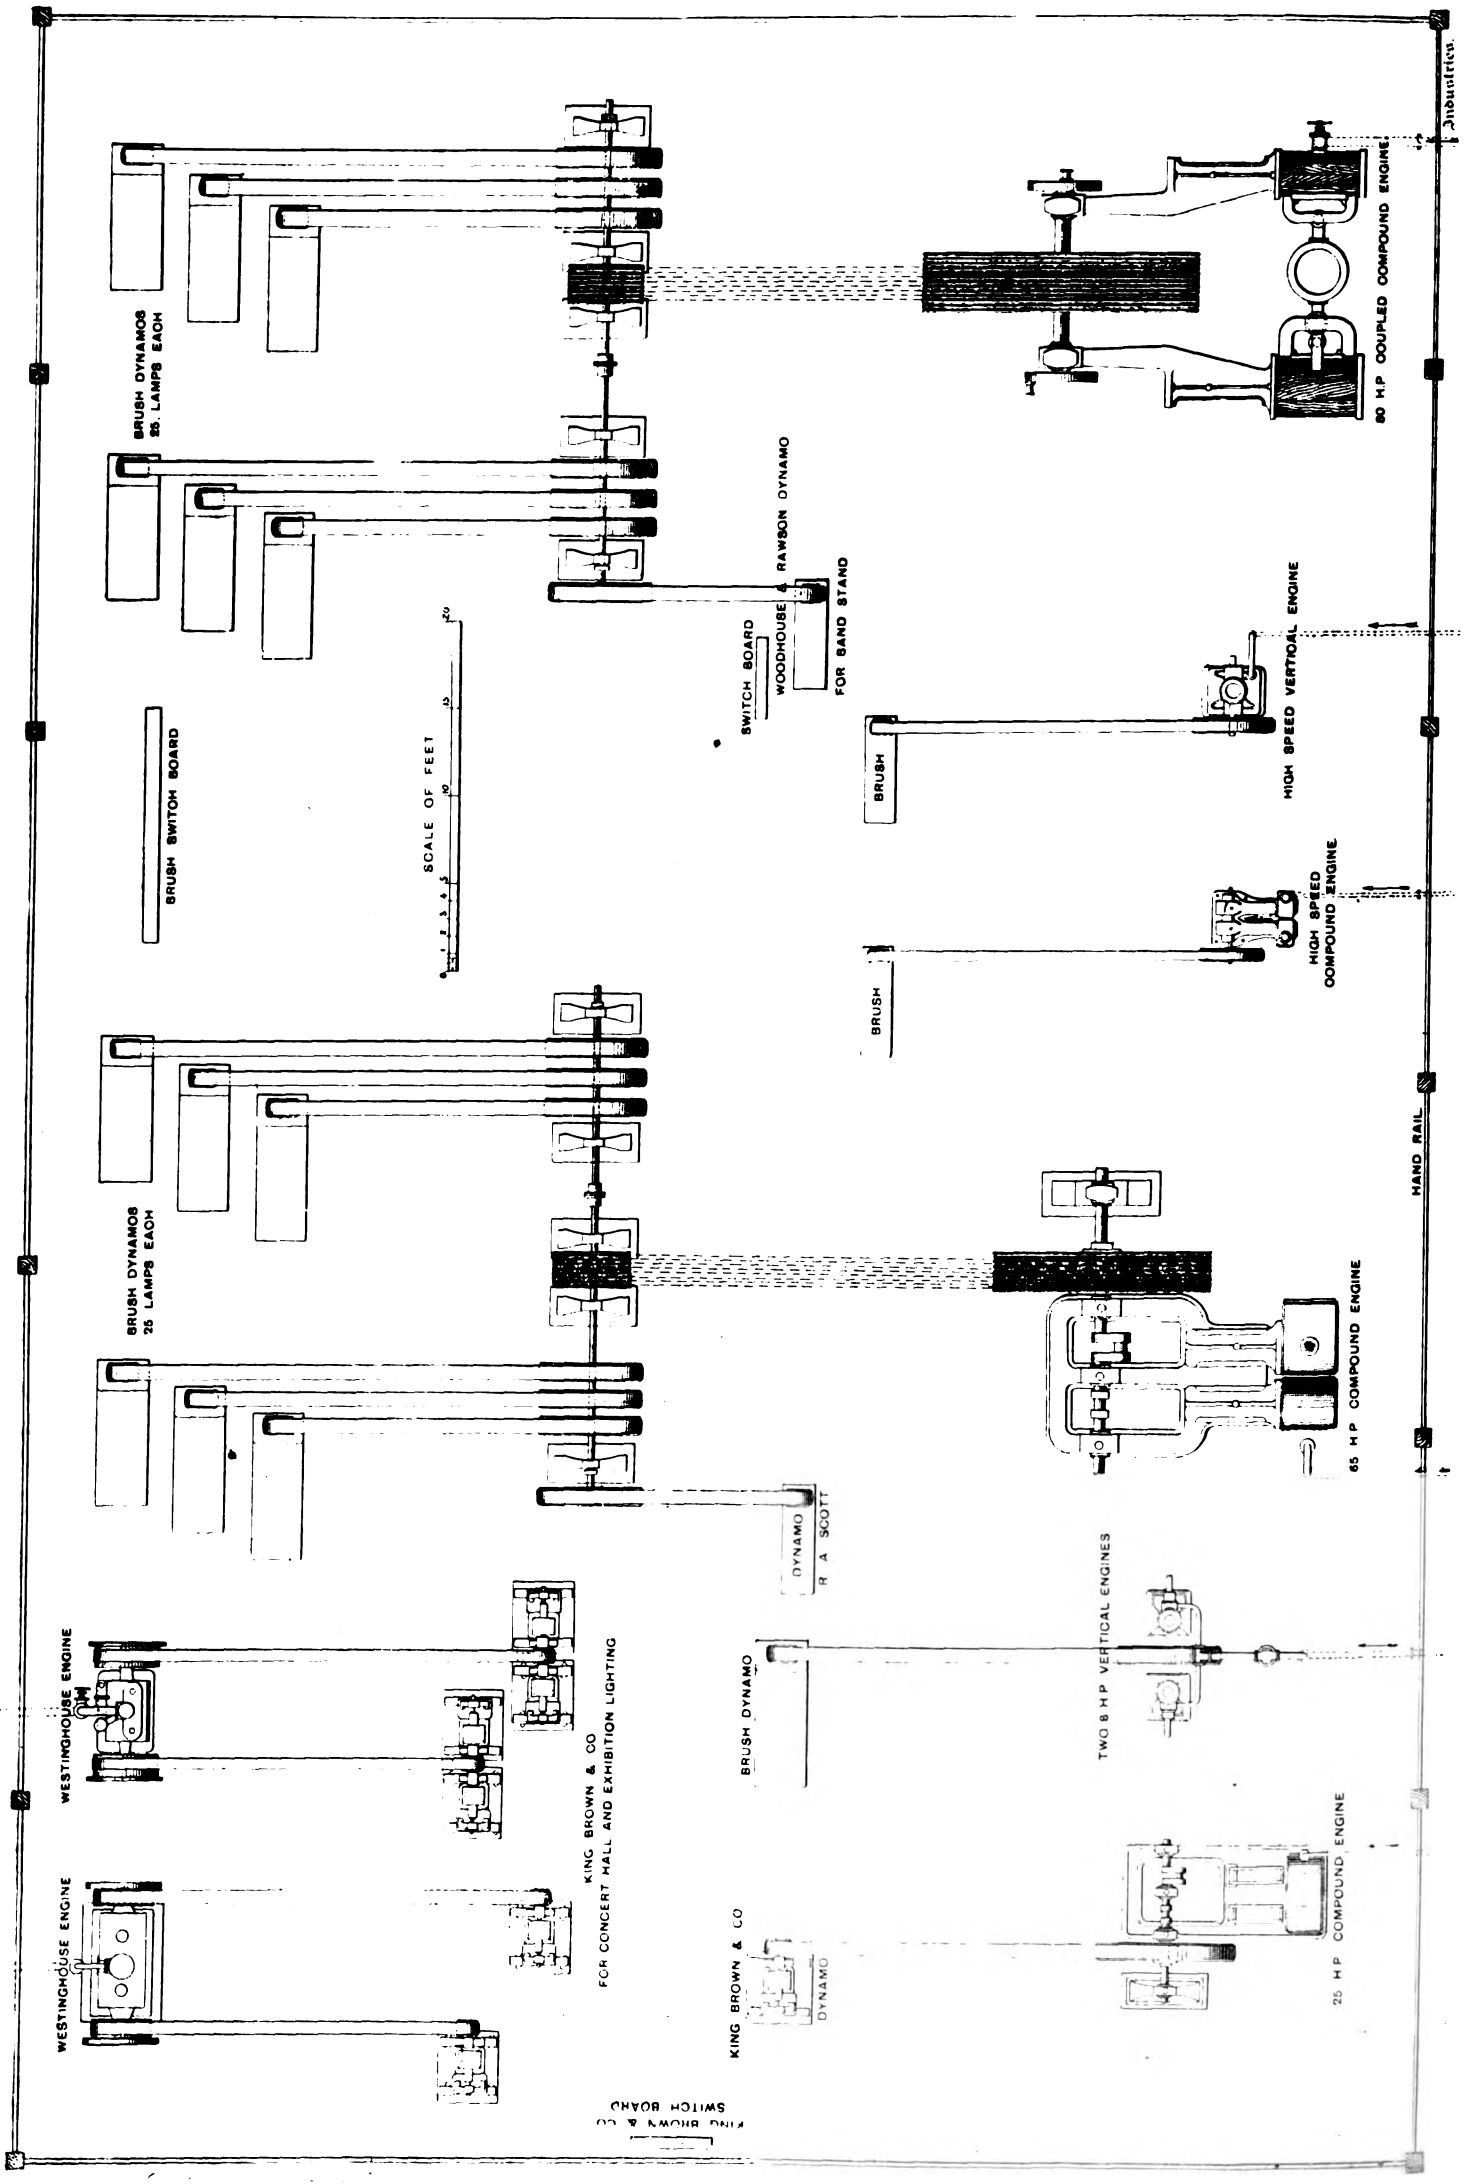
Wages Movements.—The plasterers of Newcastle have come out on strike for an advance of wages, and it is understood that some employers have complied with the demand. The policemen have commenced an agitation for an improvement in the wages scale.

New Foundry at Tyne Dock.—A firm of ironfounders, Messrs. Wheatley & Taylor, have started a new foundry in extensive premises at Tyne Dock, and as engineers are still finding it difficult to get prompt supplies of castings, the new venture is likely to be a success. A 16 horse-power Stockport gas engine has been supplied.

The Coal Trade.—The shipments of coal and coke at Tyne Dock for the week ending May 3rd amounted to 111,451 tons, being an increase as compared with the corresponding week of last year of 3,479 tons.

DUNDEE, 7th May, 1890.

Flax and Jute Trades.—The linen branches of the local trade continue fairly active. Flax is quoted at higher rates, but transactions are limited in all positions. Coarser sorts of flax and tow yarns are not in brisk demand, but manufacturers are offering well for finer qualities. A good business is passing in linens on home account. The American demand is satisfactory, and makers are busy all round. Jute is in steady demand at good prices. It is expected that the export from Calcutta of jute this year will exceed the quantity sent out last year. Jute yarns are in strong demand. Prices of Hessians are well maintained, but transactions are limited in amount.



Technical Education.—A conference of teachers and others interested in the promotion of technical education has agreed to memorialise the employers of labour as to the necessity of recognising a scientific course of study on the part of apprentices. It has also been resolved, with this object in view, to enter into communication with the Dundee Educational Trust, in order to have the conditions modified under which technical bursaries are held.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 309, Strand, London, W.C.*

FRIDAY, 9TH MAY, 1890.

SCOTCH AFFAIRS.

FORMERLY Ireland occupied so much of the public attention, that the innocent foreigner who chanced to take up a newspaper might have regarded that island as the most considerable in the Empire. Now, for the time being at any rate, Scotland steps into this position, and succeeds in securing a rather ample share of newspaper columns and public attention. The opening of the Edinburgh Exhibition, and the monopolisation of the time of Parliamentary Committees for the past fortnight, have combined to thrust Scotch affairs before the eyes of the public. The Edinburgh Exhibition has been so gallantly promoted, and so much enterprise has been exhibited in getting as many novel and interesting features together as possible, that, even if the result of these efforts had not been so successful as they happen to have been, it would have been somewhat graceless to criticise captiously. So far as electrical science is concerned, it can hardly be claimed, however, that the Exhibition meets expectations; but the railway exhibits are unusually interesting, and so also are many of the miscellaneous machinery exhibits. But an electric railway up to date, a new ship railway shown for the first time, and above all the Chemin de Fer Glissant of Messieurs Girard & Barre, exhibited last year at the Paris Exhibition and not until now seen in this country, are enough to give the Exhibition scientific interest. The external and non-scientific attractions are seductive enough to the average holiday maker, and, after all, Exhibitions are devices, not alone for instruction, but for amusement as well.

The other Scotch affairs which have been much in evidence of late are the Bills whose progress before the Parliamentary Committees have been watched with keen interest in Scotland. These are the Glasgow Boundaries Bill, the Clyde Navigation Bill, the Glasgow Police Bill, the Glasgow Subway Bill, and the group of railway Bills, chief among which are the Bills of the Caledonian and North British Railways respectively, who each want to absorb the Glasgow and South Western Railway. The Glasgow Boundaries Bill, so far as its original form is concerned, has met with a disastrous fate. Round Glasgow, as round all other large cities, there thrive groups of communities, separated from the city by no material barrier, and enjoying at once urban and at least partial rural advantages. These communities, to begin with, in some cases adopted systems of voluntary assessment for local communal purposes of a minor order, the main communal needs being satisfied by the city authorities, who supplied their neighbours with gas and water. The police administration of these districts was of a rudimentary character, but, it is only fair to add, was seldom called into requisition. One by one these communities formed themselves into burghs by means of an Act of Parliament known as the Lindsay Act. In addition to these mushroom burghs there are others of older date, whose municipal privileges in some cases it has been deemed wise to leave untouched. Obtruding beyond the city boundaries, and into the regions of the surrounding parasitic burghs, there are several public parks belonging to the city, and maintained by a rate levied on the city alone for the purpose. These parks are of course available for the inhabitants of the burghs who toil not nor pay for them, as well as for the city folk who both toil and pay for them. The burghs would neither be wooed softly nor won forcibly to meet their due share of the expenses. Things were in this pass when the Corporation succeeded in obtaining the appointment of a Royal Commission to take evidence. This Commission came and took evidence, and ultimately reported. The Report was strongly in favour of annexation all round, and the Corporation apparently rested content. It was expected that the Government would introduce a Bill which should put a stop to the perpetual bickering, and draw the whole valley of the Clyde round Glasgow into the net of the city. But the expected did not happen. The Government would not touch the subject. Still the Corporation, relying upon the Report of the Commission, went gaily forward with a private Bill, fortified by the assent of some of the burghs whose independent existence was involved. Others of the burghs, however, determined to continue the old contest, and did so to such purpose that the preamble of the Bill was found not proven, and the whole ponderous and expensive question left precisely where it was. But the representatives of the Glasgow Corporation have adopted the unusual course of seeking for leave to amend the Bill so as to exclude the dissentient and include the assenting burghs. It is, however, open to question whether or not the assent of these last was given on the understanding that the scheme was to be carried in its entirety. Among the other Glasgow Bills, the Police Bill grants increased power of sanitary inspection to the local authority, and a private Bill of the Corporation seeks powers to establish central stations for electric lighting.

The most important of the Scottish measures are, however, the Railway Bills. One of these, the Caledonian Railway Bill for a line to the Vale of Leven, has been thrown out, and the great struggle is now going on between the Caledonian and the North British Railways, nominally for possession of the Glasgow and South Western, practically for railway supremacy in Scotland. It seems that the able men who for some years past have been occupied in steering the North British Railway out of comparatively deep water into a commanding position in Scotch railway administration, saw the advantage which would accrue from their annexation of the Glasgow and South Western Railway. This railway, much smaller than either of the two great lines, is an important feeder both to the North British and to the Midland Railway Companies. For some years the association between the three railways has been very intimate, and the English company has become largely interested in the Scottish South Western through subscriptions to many of its special undertakings. At present the South Western Company and the Caledonian Railway compete together for the coast and shipping traffic by Greenock and Ardrossan, while the North British has no independent outlet to the shipping ports of the West coast, the coast line of that company being carried down the north bank of the Clyde, fruitful enough so far as tourist traffic is concerned, but barren for shipping traffic. The acquisition of the South Western Railway by the North British Company would give that company the outlet on the south bank of the Clyde which it needs, and would besides secure it further advantages—*e.g.*, direct connection with the great new dock at Glasgow at present being constructed by the Clyde Navigation Trust. From the point of view of the interest of the North British Railway the question is a simple one; the other point which it is the business of the Committee which is now

Digitized by Google

sitting on the Bills to decide—viz., the policy of this railway amalgamation considered in relation to the interest of the public—is by no means so simple. Unfortunately railway administration as an exact science has not been studied in this country in such a way as to make it possible to determine precisely the results hitherto of the extensive amalgamations which have already taken place, and, therefore, we are driven to the commonplace conclusion, that there is a good deal to be said on both sides. What is gained in point of unification of administration may not be gained by the public so much as by the shareholders; for unification means the suppression of competition, and the suppresion of competition means the probable maintenance, if not even the raising, of rates. Railway property stands in a unique position as regards State control. Save so far as these are given by express Act of Parliament, railway companies have no vested interests. Their whole existence is determined by Acts of Parliament, and, therefore, the very fact that the railway interest is represented very largely in Parliament makes it all the more necessary for us to be scrupulously careful in granting privileges which some day may become a national burden. Indeed it seems worth while keeping in mind a suggestion, which was mooted many years ago, that, failing the utmost freedom of competition among railways and the discouragement of amalgamation, it might be well to make the land and permanent way of the railways national property for which a rent should be paid, while the rolling stock should remain the property of the companies, whose lease of the permanent way should be terminable and renewable. This plan has been found to work in municipal tramway systems. It is perhaps not wholly immediately practicable so far as the railways are concerned. Nevertheless, it is certainly a serious question as to how far we are justified in acquiescing in the gradual steps of our railway system towards monopoly, especially when we remember that the railway companies collectively hold enormous tracts of land in and near all our large cities. In the hands of conscientious and responsible persons, of course, the danger to the public interest is comparatively slight; but an adverse vote at a meeting of shareholders might bring into power men who would care little for the public interest. This has happened again and again on a large scale in America, and is not purely visionary. While it is extremely difficult to suggest adequate guarantees against the abuse of monopoly, there is *primâ facie* a case for the guarantees imposed being as stringent as possible. The immediate practical settlement of the question seems likely to be the amalgamation of the Glasgow and South Western with the North British, and the granting of extensive running powers to the Caledonian Railway. Though this compromise breaks the fall, the result, should the Bill pass, will be that the North British and the Caledonian will be brought face to face in a struggle for supremacy. But the probable natural result of the proposed amalgamation of the two companies, into whosesoever arms the South Western may fall, will be the amalgamation of all the Scottish railways into one large system. Far-seeing railway administrators are known to regard this as by no means an unlikely issue.

LIGHTHOUSE ILLUMINANTS.

We have on several occasions pointed out what an energetic and persevering advocate for the improvement of lighthouse illuminants Mr. J. R. Wigham is, and we now learn, from an important paper which he has submitted to the Royal Society of Dublin, that, while the special committee appointed to investigate the matter have been taking their ease over their experiments and their report, he has been developing his system of illumination, which has already been so successful. His latest improvement seems to be due to a suggestion of Sir George Stokes, President of the Royal Society, who asked to have the details of the double quadriform gas-light fully explained to him, and the highly trained scientific man was at once able to make some suggestions which the skilled technical man was soon able to apply to a working model, and make an arrangement which is applicable to double-revolving as well as group flashing lights. Instead of being two-sided, the apparatus is made four-sided, and thus, while its speed of rotation is reduced by one-half, the duration of its flashes increases in the same proportion. The distinctive character of the light is that it transmits to the observer two brilliant flashes succeeding each other at intervals of half a minute, followed by a period of darkness of one minute, to be again followed by two brilliant flashes of half a minute apart, as before, and so on continuously. The new light has been tested at the experiment house on Howth Baily, and the results have been most satisfactory, being a regular succession of remarkable beams with an illuminating power never before attempted in lighthouse practice. We will watch with considerable interest the action of the Board of Trade and of the Trinity House in this matter. Hitherto the Commissioners of Irish Lighthouses, pushed onwards by such men as Mr. Wigham, have led the way in the development of lighthouse illuminants, while the permanent officials of the Board of Trade and of the Trinity House have always been more or less obstructive, as is easily seen from a perusal of the correspondence which has been published from time to time. The Royal Society of Dublin adopted a resolution advising their council to recommend the lighthouse authorities of Great Britain and Ireland to have the invention tested. It might save time and correspondence if the matter were referred to the special committee already appointed. The proper authorities had better take up the matter at once, for they well know by this time that Mr. Wigham will give them little rest until it has been decided.

THE LATE MR. JAMES NASMYTH.

We regret to announce the death of Mr. James Nasmyth, which took place on Wednesday last, in the 82nd year of his age. He was born in Edinburgh on the 19th of August, 1808, and was the youngest of the eleven children of Mr. Alexander Nasmyth, a well-known landscape painter. James Nasmyth early showed a predilection for mechanical pursuits, and, although he also inherited great artistic abilities from his father, he preferred to confine his attentions to engineering. At Edinburgh he attended all the scientific classes at both school and university, and he there came into contact with many leading engineers and scientists, whose acquaintance he turned to the best account. At the age of 21 he came to London, and commenced to work for Messrs. Maudslay, Son, & Field. He only stayed here for a short time, and then returned to Edinburgh, and, after making a set of special tools, he went to Manchester to start business for himself in a very small way. Here he soon found the work that poured in upon him too much for his small premises, and he secured a large plot of ground at Patricroft, near Manchester. This site of twelve acres was soon covered by a vast series of workshops, which he called the Bridgwater Foundry. In the purchase of the site and the erection of the buildings he had considerable assistance from gentlemen who saw the ability of the young engineer. Here he invented and perfected a large number of mechanical tools which are used in workshops all over the world. The steam hammer, the safety founding ladle, the double-faced wedge sluice valve, a reversible rolling mill, a pile-driver, &c., were invented at the Bridgwater Foundry, and all of them were widely applied in works all over the country. Mr. Nasmyth retired from business in 1857, and devoted himself to scientific pursuits of all kinds. He wrote several books on mechanical subjects, and also one on the moon. Astronomy was a favourite recreation of his, and he made many suggestions as regards the physical conditions of the universe, which have had an important influence on the progress of astronomical science. The application of artistic principles to the designing of pottery, &c., was also one of his favourite studies. Many anecdotes are told of his capabilities as an artist, and those who knew him agreed that if he had not been an engineer he would have shone in the art world.

THE IRON AND STEEL INSTITUTE.

The annual meeting of the Iron and Steel Institute was commenced on Wednesday, the 7th inst., at the Institution of Civil Engineers. Sir James Kitson, the President, occupied the chair. The report of the proceedings of the Council during 1889 showed that the past year has been prosperous technically and financially. The Institute now numbers 1,427 members, and 72 new members were elected at this meeting. It is expected that some 300 members will visit the United States in the autumn, and the meeting held there will no doubt be instructive, agreeable, and successful. The Bessemer Gold Medal for 1890 was presented to Mr. W. D. Allen, of Sheffield, in recognition of his attempts to preserve the high quality of Bessemer steel. Mr. Allen was one of Sir Henry Bessemer's early coadjutors, and in former years managed the works at which bronze powder, an unpatented invention of Bessemer's, was manufactured by a secret process, a secret that Mr. Allen kept for forty years.

The first paper read was on a "New Form of Siemens Furnace, arranged to Recover Waste Gases as well as Waste Heat," by Mr. John Head, M.Inst.C.E., and M. P. Pouff, of Nevers. This paper was read at Paris in September, and was adjourned for discussion to this meeting. This furnace was illustrated in *Industries*, Vol. VIII., page 75. The waste gases are directed partly through an air regenerator and partly under the grate of the producer, there to be reconverted into combustible gases, and to do the work of distilling hydro-carbons from the coal. In fact, this gas producer absorbs or utilises the heat formerly deposited in the gas regenerators of furnaces, and in doing this transforms spent gases into combustible gases. At the time the paper was written there were two furnaces at work; there are now thirteen at work for heating iron and steel, in addition to fifteen in course of construction. The advantages claimed for this furnace, as compared with solid fuel furnaces, used for heating and welding iron, are a saving in fuel, amounting to 5 cwt. of coal per ton of iron heated, a reduction in the waste of iron equal to 5 per cent. upon the weight of metal heated, and considerable saving in labour and repairs.

This paper was followed by one on calculations concerning the possibility of regenerating the gas in the new Siemens furnace, by Professor Akerman, of the Stockholm School of Mines. The calculations are of a complicated character, and insecurity is caused by the uncertainty concerning the specific heat of gases at high temperature. The author, however, concludes that, in comparison with producers such as Wilson's, in which the air for combustion is introduced by means of a steam injector, the economy of fuel with the new arrangement becomes smaller, without question, in the same ratio, as the fuel consumed in them is less than in the gas producer with which steam injectors are not used; and it is only in comparison with common draught furnaces with solid fuel, still often used in countries rich in cheap coals, that such an economy can be possible as that stated by Messrs. Head and Pouff. It is, however, with Siemens furnaces that comparison should be made; and it is very fair if, besides the fuel necessary for the steam injector, 50 per cent. from the usual Siemens furnace consumption can be saved by the new arrangement.

In the discussion that followed the reading of these two papers, Sir Lowthian Bell, F.R.S., adversely criticised the new Siemens furnace, and pointed out that in trials of new inventions better results are obtained than are obtained in practical working. Mr. Cowper, on the other hand, thought the furnace extremely ingenious, and thought that economy of fuel ought to result from using carbonic oxide as a carrier of carbon. The President had found by experience that with the Siemens regenerative furnace there was a reduction in the waste of iron equal to 3 per cent. of the metal heated. This, Mr. Head pointed out in his reply, referred to an old form of Siemens furnace. In the new form the economy of fuel was greater. The cost of the coal used is a trifle more per ton than that used in the puddling furnace.

The next paper on the list was on "The Critical Points of Iron and Steel," by Monsieur F. Osmond, of Paris. The paper was a very voluminous one, and presented points of great theoretical interest. In the absence of M. Osmond, the paper was lucidly summarised by Professor Roberts-Austen, of the Royal School of Mines. The following is a brief abstract of the paper: If iron and steel are submitted to a gradual heating or to a slow cooling between the ordinary temperature and that of fusion, and if the variations of some physical property in relation to the temperature are followed, it will be seen that these variations, besides being subject to a constant law, present remarkable phenomena at certain critical temperatures. The mode of investigation adopted consisted in observing with a chronograph what takes place when masses of iron and steel are slowly cooled. To measure the temperature a very accurate pyrometer, recently invented by Le Chatelier, was employed. This consists of a thermo-electrical couple of platinum and of platinum containing 10 per cent. of rhodium. In order to represent the results graphically, the temperatures are taken as abscissæ, and, as ordinates, the times included between the passages of the index of the galvanometer over two consecutive divisions of the scale. An arrestation in the fall of temperature is shown by a sharp point in the curve. In this way, the author investigated the phenomena observed during the slow cooling of iron, steel, and white pig iron between 1,100° C. and 600° C. The results were plotted in a series of curves, shown on large diagrams on the wall, and it was seen that the first arrestation goes on increasing from electrolytic iron, in which it is almost

Digitized by Google

nil, up to the hardest steel, where it assumes enormous importance. This point is identified by the author with the phenomenon to which Barrett gave the name of recalescence. The liberation of heat which produces recalescence is the result of the chemical combination of the iron with the carbon. The arrestation in the cooling that occurrs in electrolytic iron which is free from carbon must indicate a molecular change in the iron itself, and the author argues that iron is a polymorphous element, like sulphur, silicon, &c. There are, in fact, two kinds of iron—the α, or soft variety; and the β, or hard iron. The α-iron is pure iron at temperatures below 855° C., and iron containing certain other elements if cooled slowly. The β-iron is iron at high temperatures or if certain other elements be present after being rapidly cooled. When β-iron cools down from bright redness to 855° C. it changes into α-iron. In discussing the influence of the initial temperature, and of the rate of cooling on the position of the critical points, the author propounds a theory of hardening. In opposition to the opinion generally accepted, he believes that it is not carbon, but the allotropic β-iron, which is the principal cause of the new properties the metal acquires. In the case of tempering, the author believes that the β-iron returns to the α-condition, and the hardening carbon to the condition of iron carbide. A large portion of the paper is devoted to an exhaustive investigation of the influence of foreign elements on iron. A summary of his results was given in *Industries*, of the 2nd inst., page 409. From these results the author concludesthat Roberts-Austen's law is confirmed. That investigator, it will be remembered, by studying the effect produced on the mechanical properties of gold by the addition of an equal weight (about 0·20 per cent.) of seventeen foreign elements, has discovered a curious relation between the results obtained and the position occupied by the added metals in the periodic classification.

The names of the elements whose action on iron is known may be arranged as follows in two columns, in the order of their atomic volumes:—

I.		II.	
Name.	Atomic Vol.	Name.	Atomic Vol.
Carbon.....	3·6	Chromium.....	7·7
Boron	4·1	Tungsten	9·6
Nickel	6·7	Silicon	11·2
Manganese.....	6·9	Arsenic	13·2
Copper.....	7·1	Phosphorus ...	13.5
		Sulphur..	15·7

The elements in Column I., whose atomic volumes are ess than that of iron (7·2), delay during the cooling, other things being equal, the change of β-iron (hard) into α-iron (soft), and that of hardening carbon into carbide carbon. For these two reasons they tend to increase, with equal rates of cooling, the proportion of β-iron existing in the cooled iron or steel, and, consequently, the hardness of the metal. They are, in fact, equivalent to a more or less energetic hardening.

On the other hand, the elements in Column II., the atomic volumes of which are greater than that of iron, tend to raise, during the cooling, the change of the iron towards the normal position that it occupied in pure iron. Moreover, they render the inverse change more or less incomplete during the heating, and hasten, during the cooling, the combination of the carbon with the iron. Thus, they maintain the iron in the α condition at raised temperatures, and *a fortiori* in the cooled metal, and are theoretically a source of softness and malleability, like annealing. Thus, foreign elements of low atomic volume tend to make iron assume or preserve the molecular form in which it has itself its lowest atomic volume, and conversely with elements of great atomic volume. These conclusions are in accord with what is known of the influence of foreign elements on the magnetic properties of iron. Experiments made by the author show that within the limits in which carbon, silicon, sulphur, phosphorus, and manganese may vary in the manufacture of steel rails by the acid and basic Bessemer processes, these elements may be divided into two groups as regards permanent magnetism. In the first group carbon and manganese increase the permanent magnetism; in the second, silicon, phosphorus, and sulphur have no action on permanent magnetism.

In the discussion which followed, Mr. Wrightson referred to some experiments he made in 1879 on the change of volume of iron, when he noted two critical points. There was then no means of accurately determining temperature, and he was glad to hear that a satisfactory pyrometer had been devised. One of his critical points undoubtedly correspond with Osmond's. The critical points relating to volume, temperature, and electrical properties should be studied as a whole, and he trusted Professor Roberts-Austen would take the subject up.

Mr. Hadfield announced that he intended to instal one of Le Chatelier's pyrometers at his works, and he stated that a trustworthy indication could be obtained up to 3,500° F.

Mr. Snelus regarded the paper as an abstruse one, but thought that one point was perfectly clear—that was, that the law of Roberts-Austen seemed destined to place metallurgy on a scientific basis, a position that it had hitherto failed to occupy.

After some complimentary remarks on the paper from Sir Lowthian Bell, letters were read from Dr. G. Gore, F.R.S., who in 1869 was the first to notice a momentary molecular change in iron wire, and from Mr. W. F. Barrett, giving additional information.

(To be continued.)

THE PROPOSED GREAT TOWER IN LONDON.

Last week we gave a short notice of the Exhibition of designs for the above tower, now being held in the hall of the Drapers' Company, Throgmorton Street, London, E.C. In our double-page supplement this week we show some of the more striking designs. In the following description the figures in brackets are the numbers in the official catalogue. Fig. 1 (No. 1) shows a design sent in by Mr. M. T. Otis, of Rochester, U.S.A., of a tower of 1,355ft., with a base area of 400 feet square. It is intended to be constructed of iron, and bolts are to be used in place of rivets. Fig. 2 (No. 7) is a steel tower 1,250ft. high, with a base diameter of 192ft. The framework consists essentially of sixteen lattice legs and a central tube. Messrs. Kinkel & Pohl, of Washington, U.S.A., are the designers. Fig. 3 (No. 8) represents a very light tower of steel 1,200ft. high, in the form of a hexagonal skeleton braced around a cylindrical lift tube. Each of the feet is mounted on roller bearings. This design bears the initials W. P. Fig. 4 (No. 11) represents a tower of iron and steel 1,400ft. high, standing on a base of 500 feet square. It has four tubular columns and a central tube. Mr. E. S. Shaw, of Boston, Mass., U.S.A., is the designer. Fig. 5 (No. 20) is a design by Messrs. T. C. Clarke, Joseph Mayer, & W. Hildenbrand, of New York. This is a steel tower standing on a base area of 350 feet square, and measuring 1,280ft. in height. The skeleton is of octagonal form, but the lower part is square. Fig. 6 (No. 27) shows a design by Mr. P. Campanakis, of Constantinople, for a triangular tower 365 metres high. Fig. 7 (No. 28) is an imposing design for a steel tower 1,200ft. high, of triangular skeleton form, and carrying a huge three-faced clock. The designer adopts the motto, "Time is Money." Fig. 8 (No. 37) shows Messrs. A. D. Stewart, J. M. Maclaren, & W. Dunn's design for an octagonal tower of steel 1,200ft. high and 300ft. in diameter at the base. Mr. Robert Wylie, of Liverpool, has designed a steel tower, Fig. 9 (No. 46), 1,470ft. high, standing upon a masonry base of 8¼ acres. The framework is square at the lower extremity and octagonal above. Fig. 10 (No. 48) represents a design by Messrs. Ewen Harper, H. A. H. Harper, & John Graham, Birmingham. This tower is of slim appearance; it is 1,300ft. high, and has a base of 400ft. diameter. The skeleton consists of two equilateral triangles interlaced so as to form a hexagonal star. Messrs. Wyndham Vaughan & W. H. Tomkins, of 64, Broad Street Avenue, London, E.C., have sent in a design, Fig. 11 (No. 49), for a steel tower 1,500ft. high, with a base 500ft. diameter. The frame is of octagonal form, and consists of eight triangular columns, each of which is composed of three steel tubes with lattice bracing. Fig. 12 (No. 50) shows a handsome Gothic design by Mr. Max am Ende, of 5, Victoria Street, London, S.W. It is 1,550ft. high, and is made entirely of steel. The principal platform is situated 1,000ft. above the ground, and the lifts are situated in each of the four main columns. The design Fig. 13 (No. 51), sent in by Messrs. J. J. Webster & J. W. Haigh, of Liverpool, is for an octagonal steel tower 1,300ft. high, standing on a base 470ft. diameter, and shows ample building and platform spaces. Fig. 14 (No. 53) shows a design by Messrs. Francis Fox & George E. Grayson, of a steel tower 1,300ft. high, covering a floor space 370ft. in diameter. The skeleton consists of a double octagonal frame of sixteen lattice columns, each 20ft. square. Mr. J. Sinclair Fairfax, of 433, Strand, London, W.C., has designed a square steel tower, 1,296ft. high and 576ft. diameter at the base. This is shown in Fig. 15 (No. 54). The design shown in Fig. 16 (No. 55) is by Mr. Henry Davey, 3, Princes Street, Westminster. It is for a hexagonal steel tower 1,250ft. high. The skeleton framing consists of twelve steel columns, braced in the form of a truncated cone, on the top of which is a lighthouse tower and lamp with central staircase. Fig. 17 (No. 57) shows a design for a steel tower 1,250ft. high, having a square frame to the upper platform, and an octagonal spire above, by Messrs. R. J. G. Read & L. A. Shuffrey, 38, Welbeck Street, London, W. The design shown in Fig. 18 (No. 59) is for a "tripod tower" 1,400ft. high, the arms being hollow tapered steel tubes 30ft. in diameter at their bases. Their centres are 350ft. apart. It is intended to place the lifts in these tubes. Professor R. H. Smith & Mr. W. Henman are the designers. Fig. 19 (No. 60) shows a design by Mr. H. E. Sketchley, of 5, Gwendwr Road, West Kensington, for a steel tower 1,193ft. high, the upper portion of which is described as "equivalent to an independent tower resting upon four separate lower towers." Fig. 20 (No. 64) is a design by Mr. Lamont Young, of Villa Lucia, Naples, and is made up of a group of five towers, the main central one being 440 metres high, and supporting a large terrestrial globe, and four secondary ones. Fig. 21 (No. 72), below, shows a

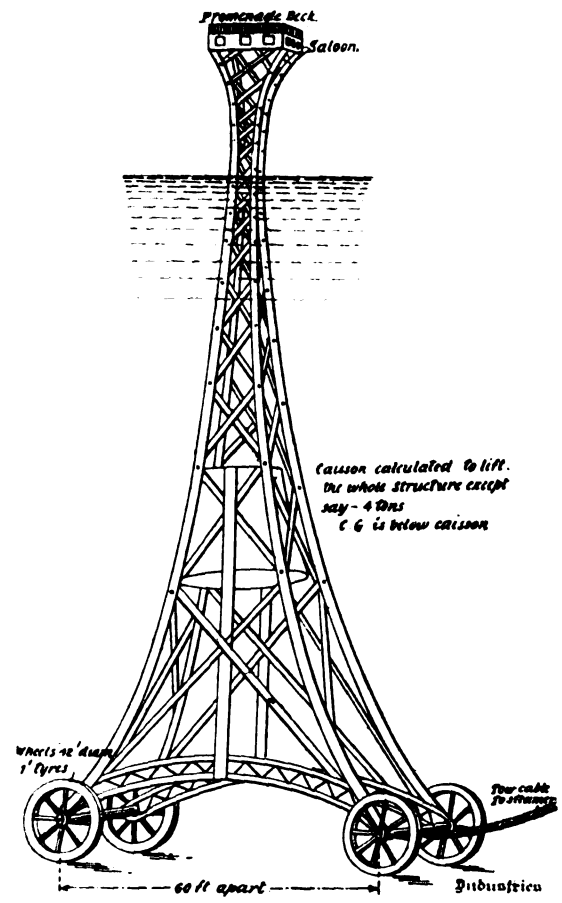

Fig. 21.

sketch of a design sent from Adelaide, Australia, which we scarcely need say was inadmissible for competition. The designer recommends it "for obviating the terrors of sickness on the Channel passage until such time as the Channel tunnel may have become an accomplished fact." The vehicle, he says, "can be towed across the Channel from one shore to the other by means of a cable attached to a steamer with great facility. It would be an enormous attraction, for fear of sea sickness and the novelty of the thing would combine to make it the talk of the day." There are other curious designs sent in which might well become "the talk of the day," but we have neither space nor desire to deal with them. As the adjudication of the Committee has not yet been made known, it would be invidious to make any comment on the designs.

Letters to the Editor.

THE INSTITUTION OF NAVAL ARCHITECTS

To the Editor of "Industries."

Sir,—In a recent issue you gave, in connection with the annual meeting of the Institution of Naval Architects, a partial *résumé* of the Society's work for the thirty years of its existence. In so far as it went, the article was perfectly correct in showing that the earlier volumes of the Transactions comprised the classics of the subject, without which probably our shipbuilders would have failed to attain that position of eminence in comparison with other nations that they have to-day. Allowing, however, for the advantages that have been derived from the reading of valuable papers, and the discussions thereon, in past years, I think it a serious question whether the Society has kept up with the times now that it has left behind its vigorous youth and reached what may be called maturity.

Signs were not wanting at the meeting just brought to a close that elements of weakness had crept in. There was, as you have already mentioned, a lack of papers. Members had to be hunted up to contribute to this year's proceedings. It is true that business had been somewhat heavy since the previous gathering, and that would militate against there being a surplus of subjects for reading on this occasion. Has there not, however, been a gradual falling off for some time in the quality of the matter submitted for criticism under the auspices of the Institution? There would not appear to be any real reason for a decline in this particular. The members exceed in point of

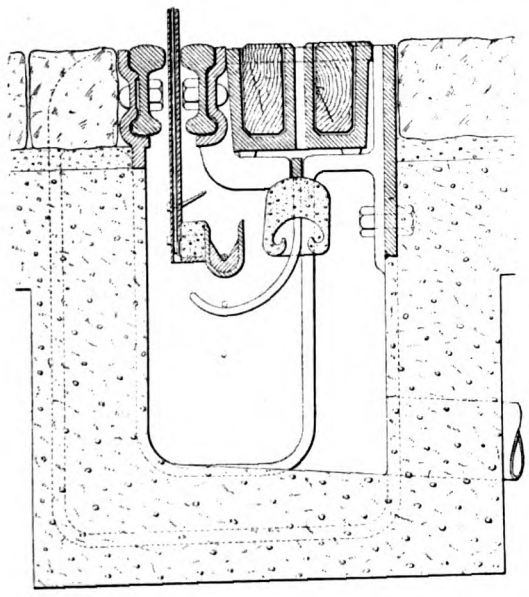

FIG. 1.

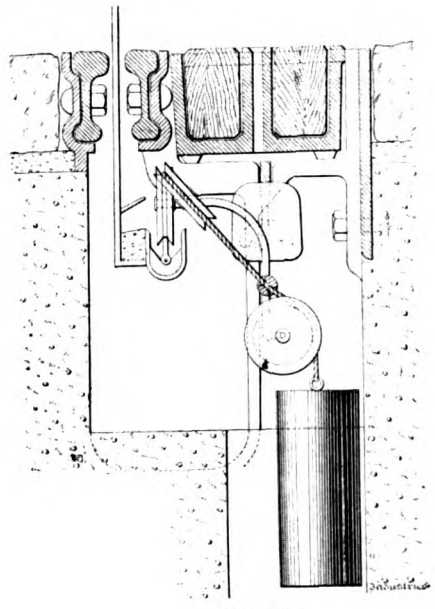

FIG. 2.

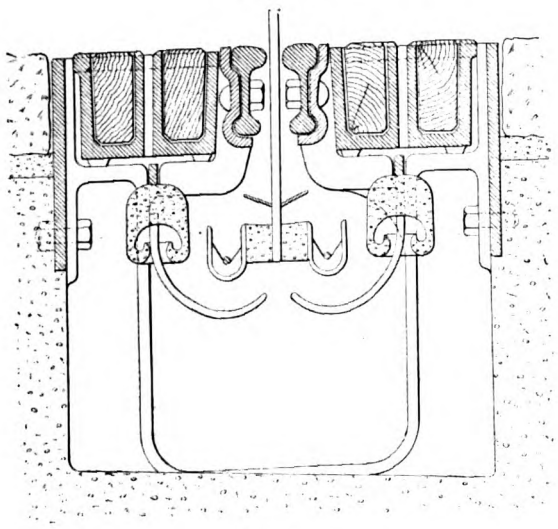

FIG. 3.

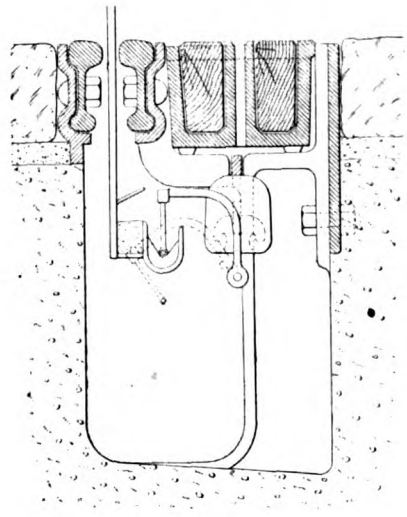

FIG. 4.

numbers any former total, and, with the developments in this branch of science, it would be supposed there was no lack of topics upon which to draw for new veins of thought. Yet it was generally acknowledged that there was a want of attraction about the meeting just closed, which has not been so strongly observable before.

To look for an answer to the probable cause of the decadence in the usefulness of which the Institution may be capable, I must call your attention to the fact that in its young days the Admiralty and Lloyd's lent a material support to the direction of affairs by permitting their officials to take a prominent part on the Council. Each department allotted an amount towards expenses, believing that it would further the improvement of ship construction. The end justified the means, for the experience made public in the Transactions has been disseminated over the world.

In another sense, however, the prominence which the Admiralty and Lloyd's secured has been a weakness. In the presence of the superior opportunities afforded to members who had such stock of information at their call others were in the background. As might be expected, the leading papers are from the pens of either Admiralty constructors or Lloyd's surveyors. Coupled with the fact that a year elapses between successive meetings—except when a summer visit is paid to outports—we also find the outside members forming other societies and coming together at shorter periods than the original Institution does. I am of opinion that no one benefits by a system which does not furnish members of the profession with the complete literature of the subject in one volume. This might have been achieved by reforms in the Naval Institution in the direction of a greater independence in its management as it emerged from childhood; an alteration, say, to four quarterly instead of one annual sitting, and an association with the sturdy rivals that have sprung up to contest for the favours of those able to contribute papers. Details will suggest themselves, but with branches fostered as part of a system, and everything appertaining to the subject regulated from a centre instead of from different disconnected head-quarters, I venture to say that members would be saved considerable trouble, and it would be to the intellectual gain of all concerned.

Yet the same mode of conducting its business rules to-day as was the case thirty years ago. Discussions have often had to be cut short to enable the programme to be completed. Now, however, that members do not come forward with sufficient readiness with material to enrich the Society's volumes, it may well be asked if the honourable record of the past is not in danger of being soon forgotten, if something be not done to revivify the present stagnation. The long intervals between the meetings seems alone a great element of weakness; but a greater one is the transference of valuable matter into channels which should form part of one great stream. I am led to make these remarks, because I think the importance of the subject demands them. I have confined myself to the main features There are other and minor ones which could also be introduced with advantage, and which would tend to strengthen the position which this leading branch of the country's trade holds. I trust, in concluding, that other members of the Institution will give their opinions on this important matter for the naval profession.

Yours, &c.,

London, 7th May, 1890. SIGMA.

SUGGESTION FOR A NEW SCOTTISH MAIN RAILWAY SYSTEM.

TO THE EDITOR OF "INDUSTRIES."

SIR,—An ingenious suggestion for the formation of a third great railway system in Scotland, in rivalry to the Caledonian and North British systems, was advanced by a correspondent in your issue of the 25th ult. The idea is to connect the Highland, Callander and Oban, and Great North of Scotland Railways with the Glasgow and South Western Railway. The necessary connections would be between the Highland Line and the Callander and Oban Railway at Tyndrum, and the construction of a line from the Callander and Oban Railway, *viâ* Ardlui, down the shores of Loch Lomond. So far no serious difficulty presents itself, excepting the inevitable destruction of the beauty of the western shore (the only practicable one) of Loch Lomond. When, however, your correspondent suggests that a high-level bridge should be built across the Clyde at Dumbarton, it is impossible to follow him in finding any advantage in such a scheme. The through traffic between England and the extreme North would hardly warrant such an enterprise; and for Glasgow and the greater part of Scotland it would be entirely out of the way. Of course, from an engineering point of view, it is no doubt quite practicable, but the carrying of a line at a high level down Loch Lomond side, and the crossing of the Clyde at a point either east or west of Dumbarton, thus avoiding the town of necessity, would not, it appears to me, be set off by any adequate compensation. Nevertheless it is ingenious. It is, of course, very likely that some day the Great North of Scotland may fall into the arms of the North British and the Highland Line into the arms of the Caledonian; the Callander and Oban Railway is at present, to all intents and purposes, a part of the Caledonian system.

Yours, &c.,

Glasgow, 6th May, 1890. M.

THE WALLER-MANVILLE SYSTEM OF ELECTRIC TRACTION.

THE essential feature of the invention is the employment of a flexible conductor sufficiently small to permit of its being placed in, or withdrawn from, the conduit through the slot. The conductor being flexible, the supports can be at long intervals; and can therefore be placed in side openings to the conduit itself By this means space is provided for large and efficient oil insulators. Removable covers are provided to these side openings or hatchways, giving ready access to the insulators. The insulators are mounted in such a manner that on removing the cover they can at once be lifted out. The collecting arm is designed so that the shank can be withdrawn through the slot, and the collector proper (or brush) through any hatchway. Under ordinary conditions the conductor simply rests on supporting arms without being attached thereto. When it is necessary to firmly attach the conductor to its support, as for instance on sharp curves, absolute flexibility is still maintained, as the supports are so designed that, whilst rigidly resisting either a longitudinal or a lateral strain, the same freedom of upward movement is allowed as in the case of the conductor itself when unattached. Simple automatic apparatus is provided at intervals to maintain a constant strain upon the conductor. The current is collected by means of a U-shaped collector in which the conductor runs; the collector lifts the conductor off the ordinary supports during its travel, and, in the case of those supports to which the conductor is attached, lifts the support itself.

A reference to the illustrations will explain the arrangements adopted in this system. Fig. 1 is a cross section through a hatchway, and shows the ordinary form of curved support on which the conductor rests, and the oil insulator to which this support is attached. The conductor is shown lifted off the support by the collector. Fig. 3 is similar to Fig. 1, but shows the arrangement for two conductors in the tube. Fig. 4 gives a side elevation of a swivelling arm mounted on oil insulators. It will be observed that the conductor is held by this swivelling arm, both being lifted by the collector, thus maintaining the flexibility of the conductor as regards upward movement, while rigidly resisting either a longitudinal or a lateral strain. Fig. 2 shows a side elevation of the tension or straining gear. This consists of a gun-metal plate or yoke mounted on two swivelling arms and supported by oil insulators, and provided with small pulleys so arranged that the conductor, or cat-gut cord in continuation of the conductor, is led to one side, so that a balance-weight can be attached thereto. This weight serves to keep the sag of the conductor between its supports constant in all changes of temperature. As the pulleys are arranged on the swivelling arm, the whole apparatus is free to lift in a similar manner to the single swivelling arm, and as the conductor is led through an eye in the shaft on which the apparatus revolves, the upward or downward movement of the tension frame in no way affects the length of the conductor, and consequently no resistance to this movement is caused by the weight of the counter-balance. This tension-gear would only be required at long intervals, occurring, say, every quarter of a mile.

It will be observed that this invention relates entirely to mechanical details, and that no new electrical conditions are introduced. The system is applicable to the distribution of electricity from a central station by any known method, whether in parallel or in series, or employing one or two conductors. It can be laid in a conduit situated either beneath one of the ordinary track rails, or between the rails, or outside the track. The first method is generally preferable for new lines, as being less costly and exposing less metal on the road surface. The second method might be desirable in some cases, for instance, in the conversion of a cable tramway into an electrical line. The fact that in this system none of the electrical parts are built in would enable this conversion to be made without practically interfering with the traffic on the line. The last method is suitable in applying the system to ordinary existing tramways, as in constructing a conduit outside the track but little interference with the traffic would be necessary. The facility with which the collecting arm can be removed renders it easy to use this system in continuation of an overhead line.

Reviews.

ELECTRICAL ENGINEERING FOR ELECTRIC LIGHT ARTIZANS AND STUDENTS. By W. Slingo, Principal of the Telegraphists' School of Science, Director of the Electrical Engineering Section, People's Palace, and A. Brooker, Instructor in Electrical Engineering at the Telegraphists' School of Science and Art at the People's Palace, London. London: LONGMANS, GREEN, & Co.

On receiving yet another elementary book on electric light, our natural impulse was to turn to the preface to find what apology the authors had to offer for adding to the numberless existing text-books and *brochures*, and we were surprised to find it stated that, in the absence of any single work covering the whole field of electric lighting, the authors have endeavoured to fill such a gap. We must confess that it was not until after careful examination of the work that we realised the truth of the statement and the admirable manner in which the gap has been filled.

The book is in no sense a text-book on electricity. Pith balls, Leyden jars, and Thales himself are even not mentioned; fur and sealing-wax are dismissed in three paragraphs; and the remainder of the 622 pages form a work which we can strongly recommend, not only to every student, but to every engineer who wishes to have an excellent account of modern electrical apparatus and machinery, with clear explanations of the principles involved.

A very considerable proportion of the 307 illustrations given have been specially prepared. The definition of current is not quite in lecture-room style, but the subsequent treatment of it is admirable. Resistance, instead of being considered as the ratio of difference of potential to flux, or as a velocity, is dealt with merely as an attribute of matter. The descriptions of modern dynamos, instruments, and lamps are very good, and though there are a few slips, we congratulate the authors on their valuable addition to the literature of technical science.

ENGINEERING ESTIMATES, COSTS, AND ACCOUNTS. By a General Manager. London: CROSBY LOCKWOOD & SON. 1890.

In an engineering establishment there is no department more important, and of which it is at the same time more difficult to obtain a thorough knowledge, than that in which the estimates of work to be done, the cost of that actually carried out, and the accounts generally are kept. In a few special cases the learner may make the round of the pattern, machine, and fitting shops, and finish in the drawing office, but the inner precincts of the counting-house are carefully guarded against all but confidential clerks and members of the firm. This, of course, is only to be expected, because few are inclined to make their system of bookkeeping, and far less its details, known to outsiders. When a practical engineer starts in business, unless he is fortunate enough to secure the services of one who has had experience in a confidential position, he is under a great disadvantage, and many firms have come to grief through the want of a proper knowledge of estimating and account-keeping. We are not aware that the subject is taught in any technical school in this country, and we have not seen any book except the one before us which attempts either to cover the ground which the author has traversed or to attain the object which he has in view. Of course we do not think that either class work or books can replace actual experience in a counting-house, still a very useful introduction to the methods of such work could be given. This could be supplemented by work in the counting-house by those who had opportunities for it. Considering, however, the exclusiveness of this department of an engineering establishment, the author has done good service in giving to the public the results of some of his experience, and placing at least a general acquaintance with commercial engineering within the reach of young men receiving a practical training in engineering shops and drawing offices, so many of whom are often placed at serious disadvantage later on in their lives for want of commercial knowledge.

We think the author has carried out his plan very successfully, and produced a book which will be of use, not only to the younger men connected with the business of engineering, but also to many principals, managers, and others who are already engaged in directing the commercial work of engineering establishments, for many of these have picked up their knowledge of methods as they found they required it, and their work is very often sadly unmethodical. The author divides his work into twenty-two chapters, each of which takes up a special department of engineering or explains the details of methods. The first five chapters are of a general nature, and contain information which will be of use to all classes of engineers, regarding the methods of making out estimates, prices, calculations, and forms. The chapter on indirect expenses should be carefully studied, as these are often neglected, and land the engineer with a deficit instead of a profit. The cost of the materials used and the labour expended upon them are, of course, the most important items, but the general expenses of the establishment ought not to be overlooked. These include rent, rates, insurance, interest, depreciation and maintenance, managers' salaries, office expenses, the wages of firemen, enginemen, and common labourers generally about the place, cartage, coal, water, gas, oil, and the thousand and one sundries which are required to keep an engineering establishment in motion. The author enters into details of the methods of estimating the cost of different kinds of millwright work, machinery of various classes, prime movers and steam boilers, and gives numerous examples of costs and estimates, which in themselves are very valuable. The parts on steam engines and boilers are specially good, and should be made an essential part of the instruction given in technical drawing classes, as they are really more important than the mere drawings. The last chapter and the longest gives an account of "costs" book-keeping. Of course, in the space available, it is not possible to give systematic instruction in book-keeping, still specimens are given of the various books required and of the forms of accounts employed, which will enable those who have not had experience in a counting-house to understand the methods which are usually adopted. On the whole we think that this will be found one of the most useful books in the valuable series by the same publishers. The author has certainly broken new ground, and his work is most creditable to him.

CAPILLAR-ANALYSE. Separat-Abdruck aus den Mittheilungen des K. K. Technologischen Gewerbe-museums in Wien. By Prof. Dr. F. Goppelsroeder. Wien. 1889.

Also, *Beilagen*, to the above. Mulhausen i. E. WENZ und PETERS. 1889.

Dr. Goppelsroeder has made a summary of his work since 1861 on this novel method of analysis, and has shown that it is capable of application in many directions. Chemists will be familiar with his earlier investigations, in which he showed that a slip of paper or thread of wool immersed in a coloured liquid afforded a simple means of deciding whether one or more dyestuffs were present in the liquid by the zones of colour produced on the paper or thread. In this way, murexide in the presence of picric acid, or a mixture of indigo and picric acid, can be readily identified, but the author has shown that the method can be applied to colourless inorganic mixtures by cutting the paper slips into separate portions and examining them or their extracts by different reagents. Mixtures of alkaloids can also be similarly treated, and in food analysis the method is serviceable in detecting the presence of adulteration in coffee, or the addition of colouring matter or salicylic acid to beers. Dr Goppelsroeder has also shown that it is possible to form an opinion on the condition of a sample of wine by this method of capillary analysis, which seems to show that there may be a future in pathological chemistry for his process. By subjecting extracts of various parts of plants to this treatment he has succeeded in showing the presence and distribution of the colouring matters in plants, and has also shown that the rate at which the dyestuffs travel in plants varies with their molecular weight and chemical constitution. Want of space prevents us from entering upon a criticism of the two pamphlets before us, and we must refer our readers to them for details of the experiments which Dr. Goppelsroeder has so patiently and ingeniously carried out.

A TREATISE ON THE METALLURGY OF IRON. By H. Bauerman, F.G.S. Sixth Edition. London: CROSBY LOCKWOOD & SON. 1890.

The new edition of this well-known manual, as we are informed in the preface, differs little from the previous one, and the additions required to bring the information up to date have been mostly placed as supplementary notes at the end. These include a table showing the progressive increase in size in the Cleveland blast furnaces; analyses of purple ore and of the gases from the Bessemer converter; the recent investigations of Sir F. Abel on the condition under which carbon exists in steel; short accounts of Mr. Hadfield's manganese steel and of Nordenfelt's "Mitis" iron; also a reference to Gjers' soaking pits and to the newer forms of open-hearth furnaces; concluding with an article on the new direct reduction processes and an account of the work done by the furnace of the Edgar Thompson Steel Works, from which a maximum yield of 419 tons of pig iron had been obtained in one day. The inconvenience of such an arrangement is to a great extent removed by a copious index, in which, however, we regret to note at least one inaccuracy, page 477 being given as the reference for Siemens' ore process, whereas this is to be found in page 469. There are few points of importance relating to the subject that go unnoticed in this work, although one could wish to see something more than a mere reference to the recovery of the tar and ammonia from furnaces worked with raw coal, a matter that is daily growing in interest. Objection may be taken to the heading under which at least one of the subjects is placed, namely, the Siemens rotator, which has to be looked for amongst mechanical puddling furnaces, presumably because, like them, it is a revolving apparatus. The author correctly apprehends its purpose, but, none the less, it would have found a more appropriate place amongst "Methods of Making Wrought Iron Directly from the Ore," a chapter that is almost entirely devoted to the Catalan forge and its imitations. There can be little doubt that the next great stride in this department of industry will be the solution of the problem which the rotator was meant to accomplish on a large and practical scale. The work is well illustrated with numerous wood engravings from drawings by J. B. Jordan, and the whole range of the metallurgy of iron is covered in a clear and succinct form that must greatly facilitate the path of the student.

THE ROYAL MAIL PADDLE STEAMER "PRINCESS VICTORIA."

IN the construction of paddle steamers rapid strides have been made on the Clyde during the past ten years, and, with few exceptions, each succeeding vessel has been a marked improvement on her predecessor in construction, general utility, and speed. Scientific research, combined with practical experiments, has done much to develop the general efficiency of this class of vessel. In the matter of acceleration of speed the most recent honour at present rests with Messrs. William Denny & Brothers, of Dumbarton, and their latest production, the "Princess Victoria," has thrown them well to the front in the "paddle world." During the past few days the "Princess Victoria," recently completed for the Port Patrick and Wigtonshire Railways Joint Committee, underwent a series of trials on the Clyde. On each trial the contract speed was exceeded, and the engines worked throughout with the greatest possible smoothness. The vessel, which is of a particularly handsome model, has been designed to accomplish the journey between Larne and Stranraer —the shortest sea passage from Ireland to Scotland— in at most two hours. Her principal dimensions are as follows:—Length between perpendiculars, 280ft.; breadth, 35ft. 6in.; depth to promenade deck, 22ft.; and the gross tonnage is fully 1,000 tons. She is lightly rigged with two pole masts carrying fore and aft sails. There are two funnels, between which is a deck-house containing a special ladies' cabin and four other distinctive cabins, all fitted up and decorated in a most tasteful manner. The main deck-house, which is built of steel, is situated forward of the fore funnel, and contains the music-room. Contrary to the usual practice in paddle steamers, the dining saloon is amidships, immediately forward of the machinery space, and is lighted and ventilated by a skylight and well overhead. Aft of the dining saloon, ladies' cabins and lavatories are fitted on the port side, while on the starboard side there is similar accommodation for gentlemen. The long poop, bridge, and forecastle are connected by broad gangways, forming a splendid promenade, from stem to stern, for first-class passengers, and is accessible from the saloon by a double staircase. Provision is made for the accommodation of a large number of deck passengers under the forecastle, while the crew's quarters, having direct communication with the forecastle, are in the lower deck. The steamer can also accommodate 750 head of cattle, the spaces set apart for them being ventilated by powerful fans driven by auxiliary engines supplied by Messrs. Matthew Paul & Co., Dumbarton. A complete installation of the electric light is fitted, the dynamo for supplying the current being driven by a Tower spherical engine.

The machinery of the "Princess Victoria" consists of a pair of compound surface-condensing diagonal engines, steam being supplied by four steel return tube boilers of the ordinary marine type, situated two at each end of the machinery space. Forced draught on the closed stoke-hold principle is applied, the four fans for the same being driven by Brotherhood's three-cylinder engines.

Quite recently the "Princess Victoria" went on her official trial, between the Cloch and Cumbrae lights, in the Firth of Clyde. As regards weather the day was most unfavourable for testing speed qualities, for a heavy westerly gale was blowing throughout the trial; notwithstanding this, however, a mean of the up and down runs resulted in a speed of 19·7 knots. On the up run against the tide the speed registered was 19·92 knots, but on the down run the speed recorded was less, it being accomplished in such a storm of wind and rain that it was impossible to keep in view the point to be steered for. On a previous private trial over the same course a mean speed of 19·77 knots was obtained, and similar results

Digitized by Google

were also recorded on a pleasure trip made two days after the official trial. The speed guaranteed by the builders was 19 knots, and much to the satisfaction of the owners this speed has been exceeded on each of the trials by three-quarters of a knot. Speaking at one of the trials of the margin obtained over the guaranteed speed, Mr. James Denny said: "The builders had certainly expected she would do something over 19 knots. . . . They had had some very reliable data to go upon, as the vessel had been very carefully tried and the results taken over an extended series of tank experiments." It is interesting to learn that from accurately conducted experiments with models Messrs. Wm. Denny & Brothers can predetermine, without risk of failure, the speed and i.h.p. of such a particular type of steamer as the "Princess Victoria." It is evident that in dealing with vessels to attain high rates of speed the importance of experimental work in connection with ship design cannot be estimated too highly; and as Messrs. William Denny & Brothers are the only private shipbuilders who have attached to their works an experimental establishment controlled by experts, they are in an exceptional position to guarantee maximum rates of speed economically and with surety.

The "Princess Victoria" is the third fast-speed paddle steamer constructed by this firm within the last two years. The other two—the "Princesse Henriette" and the "Princesse Josephine," each 300ft. in length by 38ft. in breadth—were built for the Belgian Government, for mail service between Ostend and Dover, and attained on the measured distance speeds exceeding 21 knots, which gives them the reputation of being among the fastest passenger paddle steamers afloat.

THE PHYSICAL SOCIETY.

At a meeting of this Society on the 2nd inst., Mr. C. A. Carus-Wilson read a paper on "The Distribution of Flow in a Strained Elastic Solid." The author pointed out that when a bar is subjected to tensile stress the elements of the bar are distorted by the resulting shearing stresses, which attain maxima in planes at 45° to the axis. If the bar be supposed to be divided into diagonal elements, then, if the shearing stresses are equal in the two directions parallel to the sides of the elements, the bottom points of the strained elements will be directly below their top corners, whereas, if the stresses be different in the two directions, there will be a displacement to one side or the other depending on which side the greater stress occurs. Since each inclined section is subject to the same total shearing force, the shearing stress along any diagonal section may be taken as inversely proportional to the length of the section, the bar being supposed of uniform thickness. From these considerations it may be seen that a diagonal element will be subject to equal stresses, hence the lower point of the element will remain vertically below its upper point. In this region, therefore, a horizontal straight line drawn on the unstrained bar will remain horizontal and straight on the strained bar. A diagonal element of a section, which cuts through the bar in a region where its cross section varies, will be subjected to unequal stresses, hence the lower points of the element will be displaced towards the axis. This displacement will increase as the distance from the axis increases, and an originally horizontal line will become curved at the ends. In a similar way it was shown that horizontal lines should assume various curved shapes, whilst vertical lines should become pinched inwards above and below the shoulder. To test whether the reasoning by which the above conclusions were arrived at was satisfactory, a copper bar was carefully prepared, ruled, and subjected to permanent strain. The curvatures of the various lines clearly showed the characteristics predicted by theory.

Professor Perry inquired whether it was correct to assume the stress uniform over the plane sections inclined at 45° to the axis. He also said that the general character of the flow somewhat resembled that of a viscous fluid passing from a wide to a narrower channel.

Professor Herschel thought Mr. Carus-Wilson was justified in assuming the stress uniform over the diagonal sections. The latter said he only made the assumption as a provisional hypothesis, but the results of his experiment agreed so closely with his theoretical deductions that he thought the hypothesis correct.

Mr. C. V. Boys then read two communications—first, "On Photographs of Rapidly Moving Objects," and second, "On the Oscillating Electric Spark." A collection of apparatus by which he had been able to photograph drops of water in their various stages of formation was exhibited. It consisted of a lantern and lenses, by which a trough in which the drops were formed could be strongly illuminated, combined with a camera and revolving disc with one perforation. By this means exposures of about $\frac{1}{600}$ of a second could be made about 20 times a second. The slide of the camera was about 3ft. long, and could be moved across the field by hand so as to take the consecutive impressions on different parts of the plate. The resulting photographs showed with remarkable clearness the formation, breaking away, oscillations of the drops, and their rebounding in the liquid into which they fall. By cutting the photographs into strips, each strip representing a single exposure, and mounting them on a disc, Mr. Boys had arranged a kind of thaumatrope which represented the phenomena in a very realistic manner. He also exhibited photographs of small water fountains broken up into drops by musical sounds, which he had taken by the electric spark without the aid of lenses. The shadows of the drops were sharply defined even when magnified considerably, and the various stages of transition from the liquid column to the detached particles were well shown. Finding it possible to obtain such good results from a simple spark, it occurred to him that he might get a succession of photographs from the intermittent light of an oscillating spark, and in this he was fairly successful. An apparatus devised to show the oscillatory character of a discharge was next exhibited in operation. It consisted of a disc carrying six lenses arranged in two sets of three. The members of each set were at different distances from the axis, so that the images of the spark on the screen did not coincide. The disc can be revolved at a high speed, and the successive sparks are seen as bright patches on the screen. By this apparatus a single discharge can be examined, whereas with Dr. Lodge's apparatus it is desirable to have a fairly rapid succession of sparks. Photographs of an oscillatory discharge taken with the apparatus were exhibited, and these show that the duration of the illumination is a considerable fraction of a complete period.

Lord Rayleigh said he was greatly interested by Mr. Boys' apparatus. He (Lord Rayleigh) had photographed water fountains, both when broken up and when made to coalesce, under electrical influence, but it had never occurred to him that it would be possible to get enough light or sufficient sharpness from a single spark. Mr. Boys' success he believed to be owing to the fact of his using no lenses, which would absorb the ultra-violet rays. He also thought the method might be developed so as to give shaded pictures instead of mere representations in black and white.

Mr. Gregory asked Mr. Boys if he had tried to get greater potentials for his oscillatory discharges by using Dr. Lodge's "impulsive rush" arrangement.

Mr. Trotter inquired whether the single sparks used to photograph the water fountains were as large as those required to show oscillations.

Mr. Boys said he had not tried Dr. Lodge's "impulsive rush" arrangement, because of the enormous capacity of the condensers required. The sparks used to photograph the broken-up fountain were very small, being only about $\frac{1}{4}$in. long and from a few jars.

Professor Perry asked Lord Rayleigh whether it would be possible to compare the shapes of the water drops shown in the photographs with the shapes of the liquid surfaces of revolution given by Sir W. Thomson at the Royal Institution some years ago, or whether the changes of shape were too rapid to permit of the surface tension being all important.

Mr. Boys thought the motions of the drops would be too rapid, and that inertia would play an important part.

Lord Rayleigh pointed out that by forming a drop slow enough the effect of inertia might be made negligeable until such time as the unstable state was reached; after that, however, inertia must have considerable influence on the shape.

THE GOLD CHLORINATION PROCESSES.

During the last few years the large quantity of low grade gold ores which have been valued, and the accumulation of tailings, has directed the attention of inventors to the chlorination processes. Many patents have been taken out with this object, and large sums of money have been sunk in the formation of companies to work the processes, but, so far, with indifferent results. Many of the companies have undoubtedly increased the yield from the ores, and their processes can be applied more or less profitably, but still they do not recover the whole of the gold, and until this is done there is room for further improvement. We have recently illustrated and described two or three of these processes, so that it is unnecessary for us here to repeat what we have already said concerning them. We have also pointed out (see *Industries*, Vol. VII., page 156) that the chlorination of gold ores is by no means a new process. As far back as 1848 Dr. Duflos applied successfully barrel chlorination to the extraction of gold from the roasted arsenical residues in Silesia, but even then a percolation process seemed preferable to barrel treatment. Processes of chlorination have also been in use in America for many years, and were described in 1868 by Professor Küstel. Of these the best known is the Plattner process, which is in use for very mixed ores, and which is successfully employed for the recovery of both gold and silver. The Russel process, and that founded on Longmaid and Claudet's patent of roasting the ore with salt, are also old-established and satisfactory methods of treatment.

Dr. Mears, of Philadelphia, was the first to lay any particular stress upon the influence of pressure in augmenting the solvent action of chlorine, and the Mears process may be regarded as the type of these modern chlorine extracting processes. In its simple form the roasted ore is introduced with water into a revolving barrel lined with lead, and chlorine gas is then pumped in. The improvement gained by using chlorine under pressure appears to have been discovered accidentally by Dr. Mears, through the apparatus with which he was working becoming closed; and thus the new departure, which has given rise to so many processes, may be attributed to an accident. With certain grade ores, Adolph Thies has shown that the original Mears process gives as good results without pressure as with the highest pressure (see *Industries*, Vol. VII., page 156); and in the Haile Gold Mine, in South Carolina, the plant has been remodelled by closing up the hollow trunnion, and substituting a valve for the gooseneck and acid chamber, so that the chlorine is allowed to act at ordinary pressures. It seems, therefore, of importance to recollect that different ores require different treatment, and that the additional cost of compression, forcing in air or steam, using liquid chlorine, &c., which are being recommended by their several inventors, may in many cases be a useless waste of money, and be sufficient to change what otherwise might be a remunerative process into one which leads to considerable pecuniary loss. The directors of gold mines will do well, before making arrangements with any one of these chlorine companies, to submit to each a sample of their ore, and then to receive an estimate of cost and yield obtainable by the process; and we should expect to find that, not only will the different companies find the amount of gold which can be extracted vary, but that the process which is most costly will not necessarily be the one which gives the best results. The success of a chlorination process also depends on the condition of the ore employed, and in many cases a preliminary roasting is absolutely necessary. The chlorination methods are applicable, of course, to all float or fine gold quartzes, such as those met with in the Transvaal, and also to those refractory quartzes which contain iron or arsenical pyrites. These latter cannot be treated at all by the amalgamation process, as, from the sulphur they contain, they soon foul the mercury and render it useless. In the Transvaal there are also large quantities of quartz of this character which hitherto have not been worked, but with the chlorination process it is necessary to roast such grade ores so as to convert the iron pyrites into anhydrous oxide of iron, which is unacted upon by chlorine. Some of the float gold quartzes also contain hydrated oxide of iron, and in that case it is also necessary to roast first so as to render this oxide of iron anhydrous. When an ore has to be roasted before it can be treated by the chlorination process, it seems possible that it would be more economical to roast with salt as in the Longmaid and Claudet process, or as Mauliés suggested with ammonium chloride, as then silver chloride and gold chloride are formed in the roasting process, and the chloride of gold produced can be extracted by washing with water.

In the Pollok process, we notice that the poorer ores are concentrated by roasting, with or without the use of salt, which seems to point to the conclusion that the inventors have found that their chlorination process does not extract the whole of the gold in low grade ores, and that roasting with salt is then better than their chlorination process. In most of the chlorination processes of this type a preliminary roasting seems necessary. In Count Rottermund's process the roasting is effected in a Munktell furnace, and the ore subsequently leached with water containing dilute acid before being subjected to the action of the nascent chlorine, and even then the coarse gold is not attacked, but has to be separated mechanically from the residue. In the Newberry-Vautin chlorine process we understand that, although there is no preliminary roasting, the process consists in a combination of the chlorine extraction with the amalgamation process—the mercury completing the work that the chlorine has not been able to accomplish; and in another process of the same kind, after rotating the ore with chlorine and water under pressure, mercury is added to the contents of the barrel and the liquid run over copper plates—the gold in solution as gold chloride being subsequently recovered by an electrolytic process. According to the report of the State mineralogist for California, at Deloro, in Canada, the ore, after being crushed, is roasted in a Howell-White revolving cylinder, and after this treatment is

Digitized by Google

sent to the chlorinators. In the Munktell process, which was at work at Falun as far back as 1887, a preliminary roasting is also found requisite before treatment with chlorine; and in the Plattner process, already alluded to, roasting the ore is always resorted to.

The condition in which the chlorine exists also seems to have an important influence on the results obtained by its use. Although, as we have seen, the influence of pressure on the efficacy of a chlorine process has been for a long time known, and Vautin suggested and patented the use of compressed air in the vessel to increase the action of the chlorine on the ore, it also seems desirable that the chlorine should be generated *in situ* in contact with the ore in order to get the best results. Many processes have, however, been devised in which the chlorine is generated away from the ore and subsequently made to act upon it. Thus, in Greenwood's patent, a solution of chlorine is pumped on to the ore in a closed vessel until a pressure of 80lb. to 100lb. per square inch is obtained; and, more recently, Hannay has devised and patented an apparatus for the preparation of liquid chlorine to be used for extracting gold from its ores. The Badische Anilin und Soda Fabrik have also recently described a process for compressing and storing chlorine in a perfectly dry state, which may at some future period be found to be an economical way of obtaining chlorine for use in these mining operations. Atkins also recommends (see *Industries*, Vol. VI., page 288) a mixture of steam and chlorine to be generated, and then forced along a pipe, into which the ore falls from a hopper, and then into a chamber. It is well known that nascent chlorine is far more energetic in its action than gaseous chlorine, so that it seems probable that unless these processes have advantages over the older methods they will not meet with much success.

Many processes have also been devised for generating the chlorine by an electrolytic method, and for subsequently electrolysing the gold chloride solution obtained. Those in which the chlorine is generated in contact with the ore should yield satisfactory results, but in these cases it is well to bear in mind that the production of chlorine by an electrolytic method has long been attempted for bleaching and other purposes, but has not yet been firmly established on a commercial basis. One of the earlier patents in this direction was taken out by Thickett and Noad, who electrolyse a solution of salt mixed with oxide of manganese, and then warm the ore with the solution so obtained. The Cassel process is the best known of these electrolytic processes, and in it the electrolysis of salt solution takes place in a rotating vessel in contact with the ore. Scott also has patented a process which is electrical in its action. The ore is first mixed with bleaching powder, and, after standing, is placed in a porous vessel, which stands in a larger one made of iron or zinc, and filled with salt solution. The outer vessel is then put in metallic connection with pieces of coke placed with the ore in the porous cell. As a result the gold is said to be first dissolved and then precipitated by the metal of the external vessel. Stolze has also devised an electrolytic process which consists simply in covering the ore with salt solution or sea water placed in a large wooden barrel, and then electrolysing the solution, using carbon electrodes.

Allied to the chlorination processes are those which are based on the use of bromine, and from the readiness with which this liquid can now be transported, and its comparative cheapness, there seems no reason for doubting that the processes in which it is employed will be powerful rivals to the comparatively well-known chlorination methods. Parkes patented in England the use of steam under pressure in conjunction with bromine mixed with other oxidising agents, such as chlorine, nitric acid, and chromic acid, but we have not been able to ascertain whether the process has come up to the expectations of the patentee. Simpson has overcome the difficulties attending the transport and manipulation of the liquid by first saturating a solution of caustic soda with bromine and evaporating the solution to dryness, when it forms a powdery material which can be exported in this condition. When this material is heated, with sodium acid sulphate, bromine is liberated, and if an alkaline carbonate be also added the solvent action of the bromine is increased by the pressure set up by the liberated carbonic acid. Burfeind also uses bromine water as being more convenient than chlorine gas. In presence of sulphur compounds the ore is first roasted with or without salt, and then shaken with bromine water. All the gold goes into solution, and can be run off and precipitated by sulphate of iron or a charcoal filter in the ordinary way.

This brief review of the modern methods of extracting gold from its ores by means of the halogens shows that there are many processes based upon their use, and time and further experiments can alone determine which may eventually prove to be the best. It may be that a cyanide reduction method, such as that devised by McArthur and Forrest, of Glasgow, and worked by the Cassel Company at several mines under their control, will eventually be found more efficient and more economical than those based on the use of free chlorine or free bromine. In any case, it is premature to form an opinion until the different companies have had sufficient time to demonstrate the merits of their respective processes.

THE GESNER RUST-PROOF PROCESS.

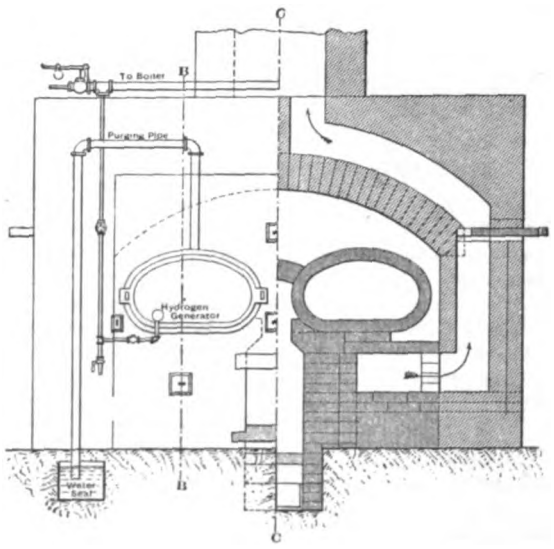

FIG. 1.

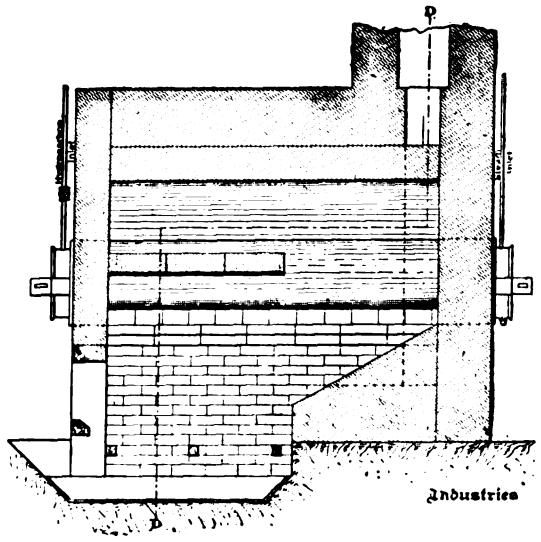

FIG. 2.

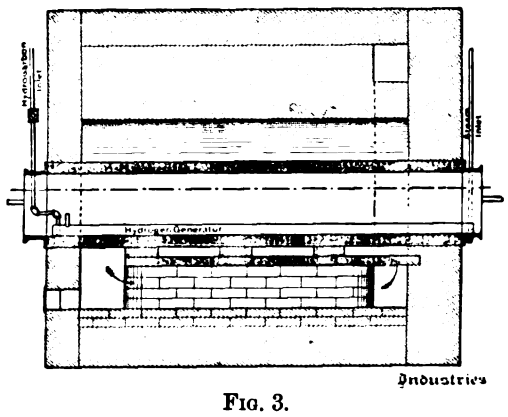

FIG. 3.

THE GESNER RUST-PROOF PROCESS.

FOR several years Mr. G. W. Gesner, of New York, has been experimenting with a process for giving articles of iron and steel a rust-proof coating. Plant has been established at South Brooklyn, which has been in operation for some time past. The accompanying illustrations, Figs. 1, 2, and 3, show its construction. It consists substantially of a bench of two ordinary gas retorts placed side by side in a furnace heated by a grate. Each retort is heated to a temperature of 1,000° F. to 1,200° F., as may be determined by the character of the articles to be treated. The latter are introduced by means of a crane and pulley, care being taken that they do not touch one another. After closing and testing the retort, the heating continues for about twenty minutes. Then steam is introduced into what Mr. Gesner calls a "hydrogen generator," shown in Figs. 2 and 3. It is a simple pipe, open at the rear end. Mr. Gesner claims that in the passage of the steam through this generator hydrogen is generated, which fills the retort. This operation goes on for thirty-five minutes, at the end of which time half a pint of naphtha is permitted to flow into the retort for ten minutes. The flow of hydrocarbon is then stopped, and the steam which has been allowed to enter the generator during the whole operation is continued for fifteen minutes longer. The whole time employed in the operation is therefore one hour and twenty minutes. The "purging pipe," which dips into an open vessel of water, as shown in Fig. 1, to the depth of 1½in., carries off any excess of gases produced in the operation. In cases where articles treated are ornamental, such as art hardware, they are given a bath of cold whale oil or paraffin oil to render them more even in tone. In other articles no oil is used. The plant now established at South Brooklyn is rated at a capacity of six tons per day of boiler tubes, 7½ft. in length, or two tons of ornamental hardware, the rate of production of treated goods depending upon the time required for handling them. The average cost in America of fuel per day is reported by Mr. Gesner to be 7s., including coal for the boiler.

To substantiate his claim that hydrogen has a function in the creation of a rust-proof coating, Mr. Gesner quotes the following analysis, made by Messrs. Stillman & Gladding, of New York, of a sample of the surface of cast iron prepared by the process: Carbon, 1·01 per cent.; hydrogen, 0·22 per cent.; sand, 6·70 per cent.; and iron, 66·10 per cent. The chemists add that the iron is present as metallic iron and as oxides of various constitution.

In order to determine whether the treatment had any adverse effect upon the strength and resistance of wrought iron and steel suitable for boiler, ship, and bridge purposes, a series of tests were made by Mr. B. H. Coffin, in charge of the testing department of Mr. Henry Warden, Germantown Junction, Philadelphia, Pa. We quote as follows from this report:—

"Five test pieces of iron were cut from a single plate ⅛in. thick, and five more similarly from a ⅜in. steel plate. These were machined to suitable sizes for the standard 8in. test piece, giving a section of about 0·71 square inch for the iron and 0·51 square inch for the steel. Three of each of these sets were forwarded to Mr. Gesner for treatment, who retained one and returned the remainder. The tests were made with a 200,000lb. Olsen machine, and the measurements with Messrs. Brown & Sharp's micrometer gauges, and are believed to be accurate.

"The pieces were gauged both before and after treatment, and showed no change. The tests show practically no effect whatever upon the iron, with the exception of a slight decrease in the elongation. As the reduction of area is not fully ascertained, it is impossible, without further evidence, to say whether or no the ductility is affected. At any rate the ductility being so low, this small reduction, if proved to exist, would be of comparative unimportance in affecting the value of the metal. The steel is benefited. The annealing undergone during the treatment has softened it to some extent; it has lost about 5 per cent. in strength but gained 5 per cent. in elongation. This metal as originally would not have come up to specifications, being insufficient in stretch. The treatment has not reduced the tensile strength below the assigned limit; at the same time it has brought the elongation up to requirements. Pieces of both iron and steel were bent cold to an angle of 45° without showing any fracture or scaling of the treated surface."

The following are the results of the tests:—

	Elongation. Per Cent.	Reduction of Area.	Elastic Limit.	Ultimate Stress.
IRON—

Untreated	21·6	43·3	41,960	58,250
	19·1	42·8	43,050	59,120
Treated	24·1	40·9	39,050	55,880
	26·0	44·9	37,390	55,220

A large variety of iron and steel goods have been already treated in quantities by the South Brooklyn Rust Proof Iron and Steel Works, among them being builders' and art hardware, roofing shingles, stove fittings, pipe and pipe fittings, parts of water meters, steam radiators, pistols, and other articles. The colour produced is a dark blue. We are indebted to *The Iron Age* for the above illustrated description.

Notes.

COAL PRODUCTION IN JAPAN.

We have on several occasions recently directed attention to the increasing importance of the production of coal in Japan, and also to the great activity in the floating of imited liability companies. The latest development of such companies seems to have reached the "Land of the Rising Sun," for it is reported that a syndicate has been formed in Northern Japan for the purpose of developing the coal mines of that region, which are said to be capable of producing 1,000,000 tons a year. The proposals include a considerable extension of the railway system and the exportation of coal to China and America.

MALTA AS A COALING STATION.

The nature of the trade done in Malta has changed very considerably in character during the past few years. Formerly it was a distributing centre for Egypt and the towns and stations along the northern shore of Africa. Of late, however, this has almost entirely ceased, and shipments are now made direct to Egypt, Barbary, and Tunis, and at present the trade of Malta is confined to the import of goods for local consumption and the export of the surplus produce of the island. For trading purposes Malta is chiefly a place of call and a coaling station, the import of coal in 1889 being 600,000 tons, mostly from Cardiff. Almost all the steamers going to or returning from the Levant and the Black Sea put in at one of its ports.

SOUTH CAROLINA PHOSPHATES.

On several occasions we have referred to this subject, and further information is afforded in a consular report from Charleston. The trade is constantly increasing, and whereas in 1880 there were 210,000 tons of phosphate rock mined, the output last year had risen to 510,000 tons. The demand for the crude rock comes from the United Kingdom, France, Germany, and even Japan, while local works last year used 80,000 tons for manufacturing fertilisers. In order to increase the value of the phosphate rock for fertilising purposes these firms mix chemicals and other fertilisers with it, so that a new import trade has sprung up in kanit from Germany, brimstone from Sicily, and nitrate of soda and muriate of potash from Chili.

BAKU PETROLEUM.

Contradictory accounts are received from time to time as to the petroleum industry at Baku, some alarmists stating that the supply is giving out. This is, however, emphatically disputed by the British Consul at Batoum, who says there are no signs of exhaustion, but that in territory thoroughly explored it is now necessary to sink the wells deeper than formerly to reach the oil-bearing strata. The total production of crude oil in 1888 was 2,580,000 tons, while last year it rose to 3,306,000 tons. In the event of the territory where borings are conducted being exhausted, it is pointed out that there are other petroleum fields along the Caspian at Khidirzindi, Aliata, and Shemakha, which have not yet been explored, as there has been no necessity to do so.

THE CHINESE TELEGRAPH CONVENTION.

About two years ago a telegraph convention was signed at Cheefoo, between the representatives of the Chinese Telegraph Administration, the Eastern Extension, and the Great Northern Companies, and we understand that it has now been confirmed by the Tsung-li-Yamen. At the time it was first heard of the agreement was objected to by the mercantile communities, as they thought that the arrangement would prevent any advantage to trade arising out of the extension of Chinese inland telegraphs to the Siberian lines on the one hand, and the Burmese on the other, and they protested against the Chinese Government being a party to a "ring" or "pool" of this character. A protest on behalf of some of the foreign mercantile communities was presented to the Government by Colonel Denby, the United States Minister, who is the *doyen* of the Diplomatic Corps, and he has been informed in reply that the protest is based on a misapprehension of the facts, and at the same time he is reminded that it was usual for vendors, not purchasers, for owners, not customers, to fix the price of their wares. The rates agreed upon are not definitely known, but it is thought that they will not be higher than at present, and that before long they will be considerably reduced. It is said that there is no mention in the agreement of a subsidy from the companies to the Chinese Government, and that there is nothing to prevent a new company from laying cables from China except, perhaps, the combined competition of the existing telegraph companies and the Chinese telegraphs. The main feature of the arrangement is that these three work in combination, and that neither can reduce its rates without the consent of the other two.

IRON AND MACHINERY IN ROUMANIA.

Bar iron was at one time exclusively imported into Roumania from Wales, but of late years, says Consul-General Sanderson of Galatz, it has been losing its hold of the market. Belgian and German makes are supplanting it. Heavy iron goods still hold their own, and machinery as a rule. Railway plant of all kinds is, however, now obtained from Germany and Belgium. The imports of tinplates from England are decreasing, while those from Belgium are advancing. Much of the hardware that was formerly obtained from Birmingham is now obtained from Westphalia; but iron and brass bedsteads, iron buckets, and sickles come almost entirely from England. The system of agriculture is very crude, and carried on without the use of modern implements other than small iron ploughs of German make. The smallness of the holdings accounts for this state of affairs.

THE TRADE OF CHILI.

From a report, which has recently been published by the Foreign Office, we learn that the commercial operations of Chili in 1888 exceeded in value those of any previous year, and that this prosperity is attributed to the favourable rate of exchange, to the better prices obtained in Europe for copper and nitrates, and to a law of 1887 which gave stability to the rate of exchange at which Customs duties were to be levied. The combined value of the general and coasting trades amounted to $324,500,000 currency, being an increase of 12·76 per cent. over the previous year. The general trade alone amounted to $140,692,000, showing an increase of more than 20 million dollars over the previous year. The Customs receipts showed an increase of 7½ million dollars, while shipping increased to the extent of 119 vessels and 169,400 tons. The imports from Great Britain exceeded those of the previous year by 28·77 per cent. Of the total imports of $60,717,698, more than 26 millions' worth came from Great Britain, while 80 per cent. of the exports went to Britain, but as these latter are classed according to the nationality of the exporting ship this return is somewhat misleading. For instance, nitrates, which formed about 60 per cent. of the total exports, are classed under exports to Britain, whereas the greater part was destined for Germany and France. Britain is credited with 26½ million dollars of imports, Germany with 14, France with 6, the Argentine Republic with 4, and the United States and Peru with a little over 3 million dollars each.

PUBLIC WORKS IN FRANCE.

A long report from Consul-General Bernal, of Havre, states that a project has been considered for deepening the River Seine, perfecting the embankments, and for making improved approaches and a new entry to the port of Havre, but owing to disputes these improvements seem to be postponed indefinitely. Two new dry docks have, however, been constructed at Havre, and several additional hydraulic cranes have been put up or are in course of erection. At Rouen, a slip, constructed at a cost of £31,000, gives some trouble. Vessels are hauled on to it broadside on. The following description is given of it:—It is 295ft. long, and can receive a vessel 312ft. long, weighing 1,800 tons. The slope of the inclined plane of the slip is 1 in 5; its breadth (in the direction of the hauling) is 168ft. 3in., and the cradle's course is 119ft. 9in., which corresponds to a vertical rise of 23ft. 6in., which course can be traversed in 5, 3½, or 2 hours, according to the speed at which the machinery is working. When the cradle is at the bottom of its course the checks are 14ft. 9in. below high water in neap tides, but owing to the projection of the side cushions for shoring, this is reduced to 14ft. When the cradle is at the summit of its course, the level of the checks is 39in. above high water at ordinary spring tides, and 30in. higher at equinoxial tides. The inclined plane is formed of 42 main beams resting on piles, to which they are mortised in a longitudinal direction; these main beams support steel rails, on which the cradle runs. The cradle is formed of 42 beams strongly framed together, which correspond with the main beams of the inclined plane; each beam also carries a steel rail; between the rails, which are beneath the cradle, and those on the inclined plane of the slip, are placed a series of rollers on which the cradle runs. The length of the cradle is divided into two parts, which measure respectively 162ft. and 132ft. 8in., which can be raised, if desired, together for large vessels, or used separately for small vessels. On the land side the cradle has along its entire length a foot-bridge, which is high enough to be always out of water. The hauling chains, 40 in number, are fastened to the cradle in the spaces between the beams; the chains are not fastened to the cradle itself, but work on movable pulleys, over which runs a compensating cable, which equalises the strain on all the chains; this cable passes alternately on a movable pulley, and on another fixed to the cradle; its two ends are fastened to the cradle. Each hauling chain works over a windlass wheel, which is driven by an endless screw, and the screw itself is driven by a bevel wheel on a shaft which runs from one end of the ship to the other. The motive power is a 50 h.p. steam engine. The British steamer "Fire Queen" and the Swedish steamer "Cuba" were unable to make use of the slip a short time ago, on account of the sand and mud, silting up with the flood tide, having rendered the gear unworkable. They had given three days' notice, and after losing a day gave it up. It is the opinion of masters that this will be of frequent occurrence. At Caen it is proposed to make extensions of the west pier at a cost of about £6,000. The Darlington Waggon and Engineering Company are building a promenade pier at Trouville. The ironwork and woodwork is English, and English artisans are engaged in erecting the pier. Harbour and dock works have been carried out at Dieppe, and a new dry dock is to be completed this year.

STATISTICS OF THE SUEZ CANAL FOR 1889.

The returns of the navigation of the Suez Canal for the year 1889, as compared with that of previous years, were recently issued in the form of a Parliamentary paper. The increase for 1889 over 1888 was 142,352 tons of shipping, and in the dues paid 1,335,306fr. The actual number of vessels, however, was less by 15, being 3,425, as against 3,440 in 1880; but this was more than compensated for by the increase in the mean tonnage per vessel, which was to be expected from the increasing tonnage of the vessels which have been recently built. Great Britain's share of the tonnage continues to increase, being last year 78·91 per cent. of the total, as against 78·65 for 1888 and 76·52 for 1887. The percentage of France has fallen slightly, being 5·33 per cent. for 1889, as against 5·83 for 1888 and 6·51 for 1887. Germany had last year 4·27 per cent.; Holland, 3·87; Italy, 2·76. Austria, Spain, and Norway follow next in succession, and the other nationalities only give a very small percentage of the total navigation.

FOREIGN SHIPBUILDING.

The following table has been published by Lloyd's Register of Shipping, showing the number and tonnage of vessels, excluding war ships, under construction at various foreign ports, according to the latest returns, excluding vessels of less than 100 tons:—

Country.	District.	Total. No.	Total. Gr. Ton.
Austria	Trieste	6	2,620
Belgium	Antwerp	1	1,500
China	Shanghai	1	550
Denmark	Copenhagen	11	8,095
France	Dunkirk	—	—
	Havre	4	—
	Nantes and St. Nazaire	5	17,590
Germany	Bremerhaven, Vegesack, Geestemunde	13	14,098
	Hamburg, Flensburg, and Kiel	22	37,470
	Rostock, Lubeck, and Stettin	17	30,775
	Danzig	1	300
Holland	Amsterdam	5	5,720
	Rotterdam	7	10,008
	Various other ports	8	11,570
Italy	Genoa	32	31,480
New Brunswick	St. John	4	2,424
Norway	Bergen, Christiania, Christiansand, Drontheim, and Stavanger	23	15,178
Philippine Islands		2	—
Prince Edward Island		2	800
Russia	Riga, Gulf of	13	4,280
Sweden	Gothenburg, Oscarshamn, and Thorskog	9	4,350
	Stockholm and Gefle	5	3,600
Turkey	Constantinople	2	416
United States of America	Baltimore	2	2,200
	Philadelphia, Camden, Chester, and Wilmington	21	31,610

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

21st April, 1890.

5991. Claridge, J. W. ..... Mechanical stokers.
5992. Newton & Quiggin ..... Couplings for pipes.
5997. Newlands & Adair ..... Steam engine.
6002. Simpkins, J. ..... Railway chairs.
6004. Fisher, R. C. ..... Sash cord machines.
6006. Sullitoe, E. ..... Washing machines.
6008. Guelbaum, D. ..... Direct-acting steam pumps.
6013. Heathorn, T. B. ..... Steering and propelling vessels.
6015. Hamillon, J. H. ..... Gas engines.
6017. Rau, O. A. H. ..... Transmitting motion.
6021. Newton, A. V. ..... Rifles (*Nobel*).
6023. Hart, A. M. ..... Spreading machines for coating fabrics with indiarubber.
6024. Bowler, T. ..... Brakes for tramcars.
6025. Fletcher, G. ..... Pump gear.
6030. Picard, R. ..... Cutting and stamping metals.
6031. Conway, P. ..... Valves.
6033. Fornander, C. ..... Friction clutches. (23rd September, 1889.)
6039. Lake, H. H. ..... Rotary engines (*Beck & Hartung*).

22nd April, 1890.

6044. Lord, W. T. ..... Steam engines.
6050. Morton, J. S. ..... Propelling vessels.
6054. Cunliffe, R. ..... Steam generators.
6055. Edward Cockbill & Son & Cockbill ..... Preventing smoke.
6057. Story, J. J. ..... Machine for cutting textile fabrics.
6059. MacLaine, A. ..... Heating feed-water.
6060. Churchill, J. D. ..... Fluid pressure reducing apparatus.
6067. Kershaw, W. H. ..... Mules.
6070. Sturrock & Macdougald Motors.
6073. Storch, E. ..... Slide or sluice valve.
6085. Capitaine, E. M. ..... Aërial navigation.
6088. Brook, E. ..... Kilns.
6092. Jensen, P. ..... Rotary engines (*Stout & Underwood*).
6098. Prall, W. E., Jun. ..... Street car motors.
6099. Eli, A. J. ..... Ironing machines (*Choteau*).
6100. Scott & Davis ..... Machines for covering wire.
6104. Victorin, A. ..... Breechloading ordnance.
6106. Wood & Houston ..... Valves for steam engines.
6107. Mewburn, J. C. ..... Evaporation of brine (*Peck*).
6108. Vicars, H. ..... Self-launching ships' refuge.
6109. William Foster & Co., Ld. ..... Machines for hulling maize (*Pfaff*).
6110. De Pass, E. ..... Apparatus for combing fibrous materials (*Imbs*).
6111. Drummond, D. ..... Tubular boilers.
6112. White, F. H. ..... Ships' propellers.
6113. Otto, N. A. ..... Gas engines.
6115. Brown, C. A. ..... Machinery for dressing skins.
6119. Lake, H. H. ..... Permanent way (*Oliver*).
6124-5. Munsie, J. F. ..... Underground conduits.
6128. Cook, J. ..... Harvesters.
6129. Smith & Tregoning ..... Crushing apparatus.
6131. Thompson, W. P. ..... Condensers (*Schulte*).
6139. Evans, G. F. ..... Transmitting power.
6140. Baker, W. S. G. ..... Railway car trucks.
6141. Hopkinson & Hopkinson Water gauges.

23rd April, 1890.

6142. Walker & Lowe ..... Looms.
6146. Crossley & Holden ..... Jacquard machines.
6154-5. Croker, G. H. ..... Machinery for cleaning cotton seed.
6161. Redmayne, R. N. ..... Pulp boilers.
6163. Howard & Young ..... Railway chairs and fastenings.
6164. Brown & Evans ..... Couplings for railway carriages.
6170. Boult, A. J. ..... Machines for re-blocking cloth (*Hutchinson & Moore*).
6176. Barker, G. ..... Harvest binders (*Jones & Wedlake*).
6181. Bayly, J. P. ..... Pipe wrench (*Smead*).
6182. Bayly, J. P. ..... Car coupling (*Toberer*).
6191. Hindell, J. ..... Railway or tramway rails.
6194. Deer, W. ..... Railway chair.
6201. Boultbee, F. R. ..... Long truck.
6203. Sonnet & Gomhault ... Measuring and registering speed.
6204. Augwin, H. ..... Machine for applying hose couplings.
6207. Cameron, D. ..... Cores for journal boxes (*Sterril*).
6208. Cameron, D. ..... Rice mills (*Tilton*).

24th April, 1890.

6229. Ainsworth, I. N. ..... Loom pickers.
6230. Harling, Harling, & Hebden ..... Winding machines.
6231. Fielding, A. ..... Pottery kilns.
6232. Rowbotham, T. ..... Wheels and axles.
6234. Gare, T. ..... Machines for finishing boots.
6238. Pallister, E. A. ..... Feeding printing machines, &c.
6240. Cleminson, J. ..... Permanent way.
6243. Fouracre, C. ..... Clack boxes.
6249. Hurrell, M. H. ..... Couplings for railway cars.
6250. Glover & Garde ..... Machinery for making warps.
6258. Kirk & Lee ..... Machinery for finishing fabrics.
6261. Andrews, G. ..... Lubricator.
6262. O'Donnell, Timmis, & Smith ..... Railway signalling apparatus.
6263. Torrance & Torrance Grinding machines.
6264. Lidstone, J. P. ..... Calculating machines.
6275. Simon, H. ..... Apparatus for recovering sludge of washed coals or ores (*Luhrig*).
6276. English, T. ..... Mounting guns.
6281. Redgate, H. ..... Twist lace machines.
6282. De Soldenhoff, R. ..... Charging coke ovens.

25th April, 1890.

6285. Bayliff & Bayliff ..... Valves of steam engines.
6289. Gregson, J. ..... Looms.
6295. Pullar, H. ..... Locking screw nuts.
6296. Smith & Smith ..... Machines for cross-cutting iron bars.
6297. Gillespie, W. ..... Machines for cleaning rags.
6302. Tyler & De Vesian ..... Three-way hydraulic valves.
6303-4. Bentley, J. ..... Looms.
6307. Armstrong, W. ..... Holding and detaching gear for ships' boats.
6316. Fox, S. ..... Manufacturing steel.
6317. Hornish, F. W. ..... Boiler cleaners.
6318. Lacy, H. ..... Railway couplings.
6321. Scott, A. ..... Controlling steam engines.
6323. Vernon, T. T. ..... Consuming smoke.
6324. Taylor, A. ..... Steam hammers.
6327. Witter, E. E. ..... Adding machines.
6334. Schneider, H. ..... Breechloading ordnance.
6336. Holmström, C. ..... Breechloading guns.
6340. Taaffe, W. J. ..... Machinery for the manufacture of felt hats.
6342. Kelly, G. ..... Flat coiled springs.
6344. Singer & Judell ..... Apparatus for pressing wool.
6349. Brookes, A. G. ..... Drill grinding machines (*Higgins & Morgan*).
6351. Sloan, H. ..... Hackling machines.
6353. Cole, Dobson, & De Mouzilly ..... Knitting machines.
6354. Willans, P. W. ..... Steam engines.

26th April, 1890.

6357. Brain, H. G. ..... Centrifugal governors.
6360. Bollé, C. ..... Wheel ploughs (*Moser*).
6368. Croker, G. H. ..... Machinery for cleaning cotton seed.
6369. Kellner, C. ..... Pulp boilers.
6370. Dickinson, A. ..... Joints of tramway rails.
6371. Bamforth, S. ..... Preventing smoke.
6373. Vonhof, E. G. ..... Tubular boilers.
6374. Ives & Barker ..... Elevated railways.
6375. Greaves, J. E. E. ..... Steam engines.
6376. Sutor, W. J. ..... Railway chairs.
6379. Moverley, R. ..... Thrust bearings.
6380. Bartholomew, C. W. ... Sharpening miners' picks.
6382. Haddan, R. ..... Storing and expelling liquid under pressure (*Azcona*).
6390. Evans, E. ..... Grain binding harvesters.
6393. Milovanovitch - Koka, K. R. ..... Repeating firearms.
6396. Simonds, G. F. ..... Manufacture of ball bearings.
6398. Dürr, G. ..... Steam generator.
6399. Von Langer & Cooper Reverberatory furnaces (*Pietzka*).
6400. Von Langer & Cooper Utilising waste heat of furnaces (*Pietzka*).
6404. Simonds, G. F. ..... Axle bearings.
6407. Dawson, H. T. ..... Gas engines.
6410. Alfred, J. W. ..... Tip waggons.

ELECTRICITY.

21st April, 1890.

5996. Sayers, W. B. ..... Electric incandescent lamps.
6000. Scott & Laurence Paris & Scott ..... Electric distribution.
6005. Sayer, G. H. ..... Electric lamp adjuster.
6032. Dewey, M. W. ..... Electric heating apparatus.
6037. Dewey, M. W. ..... Electric railway vehicles.

22nd April, 1890.

6041. Dewey, M. W. ..... Transformation of electrical energy.
6082. Waller & Manville ... Electric propulsion of vehicles.
6083. Gordon, J. ..... Electric propulsion of tramcars.
6120. Kintner, C. J. ..... Electrical distribution.
6126. Radcliffe, R. D. ..... Electrical signalling apparatus.

23rd April, 1890.

6156. Schultz, G. ..... Electrical switch.
6177. Barker, G. ..... Secondary batteries (*Woodward*).
6202. Stepanow, S. ..... Electrolytic bleaching.
6223. Ancizar, M. ..... Galvanic batteries (*Bayon*).

24th April, 1890.

6236. Jarman, A. J. ..... Storage battery.
6266. Marx, J. ..... Electrolysis.
6267. Marx, J. ..... Connecting electrical conductors.

25th April, 1890.

6326. Batault, E. ..... Electricity meters. (28th September, 1889.)

26th April, 1890.

6359. Peddie, H. J. ..... Electric railways.
6389. Blattner, A. ..... Electric motor.
6392. Bláthy, O. T. ..... Safety fuses.

CHEMISTRY.

22nd April, 1890.

6046. Pointon, J. ..... Alkaline silicates and aluminates, &c.
6047. Pointon, J. ..... Alkaline aluminates.
6048. Pointon, J. ..... Alkaline silicates.

23rd April, 1890.

6195. Bromhead, S. S. ..... Colouring matter (*Grünau, Landshoff, & Meyer*).
6216. Vautin, C. T. J. ..... Extraction of gold and platinum
6217. Griffin, S. ..... Producing gas

24th April, 1890.

6256. Rock, T. D. ..... Anthracite gas.
6274. Imray, O. ..... Colouring matters (*Meister Lucius & Brüning*).

25th April, 1890.

6333. Lyte, F. M. ..... Magnesium oxychloride.
6346. The British Alizarine Company, Ld., & Bendix Alizarine compound for dyeing and printing.

MISCELLANEOUS.

22nd April, 1890.

6087. Goodman, J. ..... Planimeters.
6127. Norman, A. H. ..... Treatment of ramie.

23rd April, 1890.

6149. Tullis, J. K. ..... Belting.
6169. Blackwood, J. ..... Belting.

24th April, 1890.

6226. Walsh, I. ..... Spindle bolsters.
6245. Moor, C. G. ..... Treatment of sewage.
6246. Bonné, C. R. ..... Prevention of incrustation (*Bender, Wüster, & Reinhard*).
6252. Longshaw, J. ..... Purifying water, sewage, &c.

25th April, 1890.

6315. Harrison, R. ..... Bleaching, &c., fibrous materials.
6347. Lake, H. H. ..... Driving belt (*Schultz & Alvord*).

26th April, 1890.

6377. Bartholomew & Ward Fog signals.
6397. Hill, F. B. ..... Treatment of sewage.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1889.

3758. Dowland.
6867. Richardson & Hill.
6884. Atkinson.
6901. Macgown.
7001. Mitchell.
7341. Waddell.
7346. Armstrong.
7386. Clegg.
7839. Peyman.
8111. Hassall.
8299. Willcox (*Farbenfabriken vormals Friedrich Bayer & Co.*).
8584. Drury.
8702. Emery.
8762. Turnock.
8862. Thorp.
9032. Allmark.
9166. Wells.
9278. Pearce & Webb.
9498. Nordenfelt.
9529. Sinclair.
9568. Allchin & Walker.
9591. Cunningham.
9717. Dunbar.
9748. Hunter & Marshall.
9768. Hurst.
9796. Blakely.
9824. Blackwell & Blacklock.
9880. Moffatt.
9964. Rignault.
10025. Entwistle & Entwistle.
10053. Seck.
10065. Griffith.
10104. Bartsch (*Lechler*).
10125. Frankenburg.
10142. Ramage.
10157. Jeffries.
10204. Jacoby.
10229. Wise (*Maggi & Co.*).
10248. Corney & Francis.
10260. Griffiths.
10277. Dewar & Redwood.
10292. Evans.
10303. Wood & Wood, Jun.
10329. Edmeston.
10362. Hale.

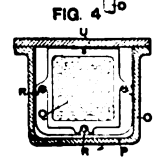
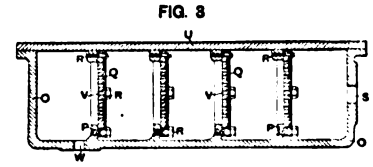
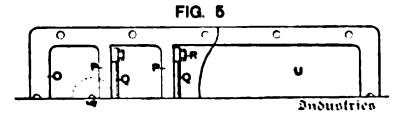
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.



ENGINEERING.



HOISTING MACHINERY.—*Pickering Ld., J. T. Pickering, E. W. Sant, & A. R. Davies, Stockton-on-Tees.*—In this machine an automatic intermittent stopping action is obtained by means of differential gear, working in connection with the ordinary starting arrangement, but leaving it free for independent use. Suitable powers of adjustment are provided so that by the use of the invention a hoisting machine can be made to arrest itself automatically at any point in its travel. The winding shaft is geared by toothed wheels to a countershaft carrying the driving belt pulleys. Upon the ends of these two shafts are loose drums geared together by an endless chain. The drum upon the winding shaft is fitted with differential gear, which imparts to the drum as the shaft is revolved a reduced rotary motion. This motion is transmitted by the endless chain to the second drum whose surface is grooved similarly to a worm. A series of small rollers or bowls constituting a rack are secured to the sliding rod of the belt shifting forks. These bowls work in the manner of teeth in the grooves of the second drum, so that as this drum is revolved the striking gear gradually shifts the belt from one pulley to the other, and stops or reverses the motion of the hoisting barrel. Claims: (1) In the construction of hoisting apparatus, the combination of differential gear, a grooved wheel, and shifting bar, fitted with rollers as described; (2) the combination and arrangement of the several and respective parts together forming the improvements in apparatus for starting and stopping hoisting machinery as described.—No. 5704. April 3rd, 1889. 8*d.*



PURIFYING SEA WATER.—*V. B. Lewes, Greenwich.*—The salts of calcium and magnesium are removed from sea water by this invention, leaving it fit for use in boilers, &c. The sea water is mixed with some salt that precipitates the calcium and magnesium salts, and the mixture is then heated under pressure. After this treatment the water is filtered, and is then ready for use. The apparatus used in this method is as illustrated. Figs. 1 and 2 are respectively a vertical section and plan of the precipitating vessel; Figs. 3, 4, and 5 vertical longitudinal section, transverse section, and plan of the filter. The precipitating vessel A has an inlet pipe B for admission of sea water, outlet pipe D for discharge of impurities, and outlet pipe F for the treated water. The chemical used for precipitating the salts is carbonate of soda, which is introduced at the top opening H. To raise the pressure in the vessel the water is heated by a current of steam passed through

FIG. 1

FIG. 2

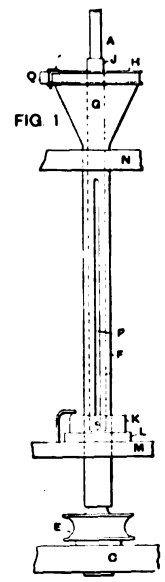


FIG. 4

FIG. 3

FIG. 5

the coil I. The filter comprises a vessel O fitted with a series of perforated partitions Q, composed of two iron plates, with a suitable filtering medium between them. S is the inlet, and W the outlet. Claim: The herein-described method or process of treating sea water for use in steam generators, by mixing with the water a salt or compound such as carbonate of soda, capable of precipitating the calcium and magnesium salts contained in the water, heating the mixture to boiling in a closed heating vessel separate from the steam generator in which the purified water is to be used, allowing the insoluble precipitated impurities to deposit in the said closed heating vessel, and causing the supernatant water on its way to the boiler to pass through a pipe having its open end above the bottom of the closed heating vessel and through a filter external to the said heating vessel as set forth.—No. 5339. March 28th, 1889. 8*d.*

SPINNING, &c., MACHINERY.—*P. Wallace, Huddersfield.*—The apparatus referred to in this invention is employed in spinning, doubling, and roving wool and other fibres, the object being to wind the yarn upon a bare sleeve. If the sleeve is composed of metal a tube of paper or other suitable material is placed upon it. An elevation and vertical section of these improved parts are given in Figs. 1 and 2 of the illustrations. A represents the spindle, resting in a footstep B, attached to the lower rail C, such spindle being secured in a bush formed at the top of the tube D, rising up from the wharle E, by which the spindle is driven. There is also fixed to the tube D of the wharle another tube F, extending upwards, on the top of which is a conical cup G, made with one or more rings or flanges H for receiving a traveller I (Fig. 4). On the spindle is placed loosely a sleeve or tube J, upon which the cop is formed; the bottom of

FIG. 1

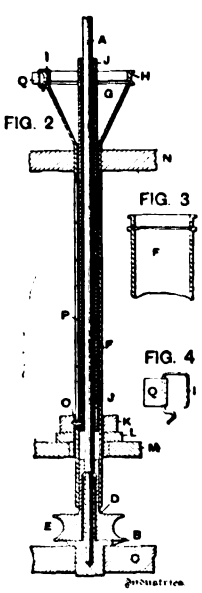

FIG. 2

FIG. 3

FIG. 4

the tube J rests upon or is taken hold of by a pin or stud O projecting from the loose collar K and resting upon a washer L carried by the lifting rail M, so that as the lifting rail is made to reciprocate up and down the tube J is made to rise and fall with it, and the yarn is built on the tube in the form of a cop. It will be understood that the wharle E drives both the spindle A and the tube F with its cup G, but the tube F is made with a long slot P through which the pin O slides up and down as the lifting rail rises and falls. A rail N is employed to steady the tube F and parts connected therewith. The traveller I is carried around on the ring H by the yarn as it is being wound, and its motion is retarded by a wing Q. Claims: (1) In machines for spinning, doubling, and roving yarns, the employment of the outer tube F, having a cup G on the top thereof, whilst the bottom of the said tube extends near the bottom of the spindle, in combination with the reciprocating tube J and the spindle A, all arranged as described and shown; (2) in machines for spinning, doubling, and roving yarns, the employment of the outer parallel tube F, the bottom of which extends near the bottom of the spindle, in combination with the reciprocating tube J and the spindle A, all arranged as described and shown; (3) in spinning and other machinery, the use of a traveller I having a wing or flap Q for retarding the speed of the said traveller in manner substantially as described.—No. 8410. May 21st, 1889. 8*d.*

PUMPS.—*G. Savin, Margate.*—This describes a hand-pump of the three-throw type, which may be easily transported and quickly brought into use. The pump comprises three vertical pump barrels communicating at the bottom with a common suction chamber fitted with perpendicular or horizontal suction connections, according to the circumstances under which it is worked. The pump barrels also open at the top into a delivery chamber provided with a suitable delivery pipe. The three-pump barrels, with the suction and delivery chambers, are mounted in a frame composed of a pair of A standards braced together and adapted to be temporarily fixed in the required position for use. The pump buckets are connected by stirrup-shaped connecting rods jointed to the bucket rods, which slide in cross-guides at the top of the delivery chamber. The crank shaft is mounted at the upper part of the frame and provided with winch-handles and fly wheel. Claim: The herein described construction of portable hand-pump.—No. 7433. May 3rd, 1889. 6*d.*

TWISTING, &c., YARNS.—*T. Hall, Huddersfield.*—Reference is here made to machines employed for reeling yarn, the improvements consisting in combining with such machines apparatus for enabling two, three, or more yarns or threads to be twisted or doubled and wound on to the ordinary reel at one operation. The necessity of twisting or doubling such yarns upon an ordinary mule is thus obviated. In the figures A represents the reel, C a spindle (one only being shown). The spindle has two discs, one for supporting the cops E, and the other carrying eyelets for the threads of the cops. The threads are passed upwards through

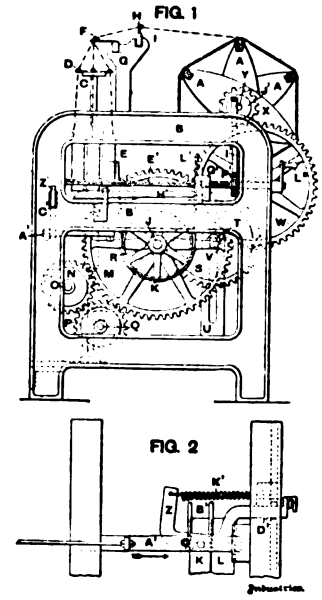

FIG. 1

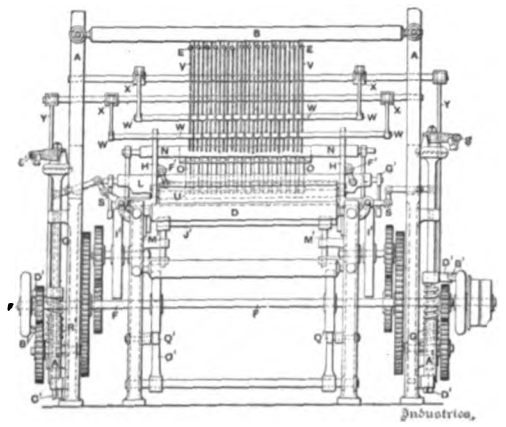
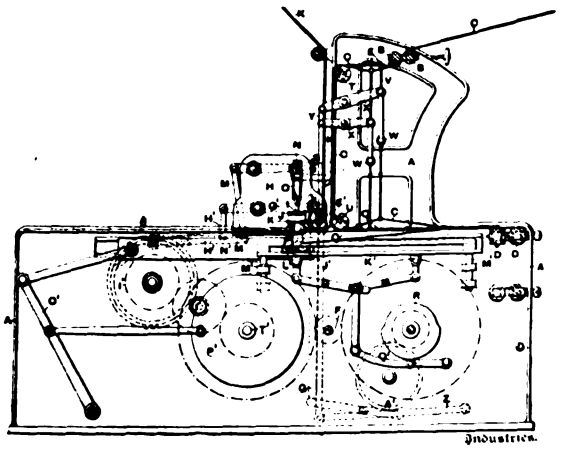
FIG. 2



a single stationary eyelet F, and thence to a second eyelet H, secured to a reciprocating bar I, and finally it is wound upon the reel A. The rotation of the reel draws the yarn from the several cops, which are rapidly carried round by the spindle, and the yarns thus twisted together into one thread in the usual manner. The reciprocating motion of the bar I causes the twisted yarn to be traversed laterally on the reel to build the yarn to the required section upon it. The speed at which the spindles are driven determines the number of twists to be put in the yarn a certain length. The mechanism employed for rotating the spindles and the reel consists of a number of gear wheels and shafts driven off the main shaft J. In order to automatically stop the machine when the hanks are completed, a hook-ended lever Z (Fig. 2) is hinged to the setting on rod A^1 carrying the striking fork B^1. In Fig. 2 the belt is shown upon the fast pulley, the forks being held in that position against the resistance of the spring K^1 by the projection D^1 engaging with the frame of the machine. By lifting the lever Z it is obvious that the projection D^1 will be disengaged, and the fork B^1 moved over to the loose pulley. The lever Z is raised at the required instant by a sliding rod H^1, propelled by a screw block G^1, whose screw is rotated by a ratchet wheel F^1, driven by the crank disc J^1 upon the reel spindle. Claims: (1) Apparatus for doubling yarns and simultaneously reeling same in manner substantially as described; (2) in apparatus for doubling yarn the revolving plates for carrying cops, together with the revolving plates for carrying eyelets in combination with the reeling apparatus.—No. 6765. April 23rd, 1889. 8*d.*

BEARINGS FOR SHAFTS.—*C. Taylor & G. B. Taylor, Birmingham.*—Instead of making bearings of top and bottom parts, as is usual, the inventors make them solid, and slit the metal radially and longitudinally around the bearing hole, to admit of adjustment. One slit is carried right through the metal in the manner of a clamp, and by a bolt passed through them the parts are closed. Claim: Constructing an elastic bearing for rotating shafts, axles, and spindles, by dividing the bearing part of the cheek, upright, or support, by one or more slots opening into the hole in which the shaft-axle or spindle works, so that the divided or slotted bearing is capable of a slight opening and closing at the slot or slots, and the consequent enlargement or diminution of the spindle or axle hole, and the combination with the said elastic bearing of an adjusting screw and clamping screw, or adjusting or clamping screws, as described.—No. 9058. May 31st, 1889. 8*d.*

Digitized by Google



COIR YARN MAT MACHINERY.—*E. Hodder & R. Swain, Manchester.*—A loom is employed for operating the warp and weft composed of coir yarn in conjunction with an arrangement of mechanism for first producing the thrums, and then carrying them forwards on to and along the warps so as to become interwoven with the warp and weft. In the illustrations, Fig. 1 is a front view of the improved machine and Fig. 2 a side elevation. On the top of the loom frame A are a series of rollers B, to create the necessary drag upon the warps C. The warps are led from these over a roller T, down to a roller U, and thence forward to a pair of delivery rollers D. On their way the warps C are passed through eyelets E, attached to the top and bottom heald rods W, which are carried by the levers X, in turn con-

FIG. 1.

nected to the tappet lever Z of the tappet A^1. The loom has an ordinary shuttle, operated by the tappet B^1. The picking shaft G at each side of the loom is provided with a tooth or projection D^1, to which is attached one extremity of a strong spiral spring R^1, having its lower extremity affixed to the frame side of the loom. When the shuttle is timed to be thrown across the loom, the tappet B^1 comes in contact with such projection D^1, and has the effect of winding up or increasing the tension of the spring I, and of bringing the arm or distaff S^1 back to its farthest point. It will be seen that when such tappet B^1 is passed, the projection D^1 is instantly released, the spring recoils, and, actuating the picking shaft G, causes the shuttle to be thrown across the loom. It now remains to describe the formation of the thrums, and how they are carried forwards on the warps. A frame H extends across the back of the loom, and is provided with a series of vertical holes I. Across each of these holes is formed a horizontal passage J, to receive the ends of the yarns required to be formed into thrums. These thrum yarns K are drawn off a reel at the back of the loom, and are pushed into the horizontal passages J by feeding rollers E^1, intermittently revolved. Behind the feeding rollers is the cutting-off knife L, which descends and cuts off the thrum yarn at the proper instant. The knife is raised and lowered by the cam wheel I^1 and its connecting levers G^1 H^1, the lever H^1 carrying at its extremity a bowl running in a groove in the cam wheel. The bar O is similarly operated by a groove and bowl upon the opposite side of the cam wheel I^1. To this bar are secured chisel-shaped plungers, projecting slightly into the holes I. In descending, these plungers are given a half turn upon their axes. As the thrum yarns are applied to the horizontal passages J, they are pushed forward by the plungers, and formed into the necessary U shape, and upon passing out at the bottom of the holes are turned to the proper angle, to be carried forwards by the thrum carriers on to the warps, to form the coir pile. The thrum

FIG. 2.

carriers consist of a set of projections, arranged comb-like along the upper surface of a transverse bar J^1, capable of sliding to and fro in the horizontal guide grooves K^1. Claims: (1) The combination and arrangement and mechanism for the manufacture of coir mats, substantially as hereinbefore described and illustrated in the accompanying drawings; (2) in machinery for the manufacture of coir mats and other similar coir fabrics, the employment of thrum-forming mechanism, mounted and operating substantially as and for the purpose hereinbefore described and illustrated in the accompanying drawings.—No. 5062. March 23rd, 1889.

FEED-WATER APPARATUS.—*L. J. Porion, Nord, France.*—The invention consists essentially in utilising the rise and fall of a float within the boiler, not for regulating the passage of the feed-water as is usual when a float is used, but for controlling and regulating the supply of steam from the boiler to work the feed-pump or other appliance. Upon the top of the boiler is vertically connected the steam supply pipe for the feed-water appliance. The pipe is fitted with a valve, which is opened and closed by an up and down vertical movement. The rod of this valve is connected to the float directly below it. Thus, as the water falls in the boiler, the float and the valve fall with it, and steam is passed to operate the feed supply, the effect being reversed as the water increases in height. Claim: The herein-described apparatus for ensuring an automatic and continuous supply of feed-water to steam boilers, consisting essentially of a plug-valve received in a conical seat and attached to a float as described.—No. 8797. May 27th, 1889. 6*d.*

CONVERTERS FOR METAL.—*A. J. Boult, London. (J. W. Bookwalter, Springfield, Ohio, U.S.A.)*—In converting iron according to the Bessemer process there is a tendency to produce local currents in the metal so that only a portion of the metal comes under the full action of the air blast. To break up these currents and bring the whole successively under the action of the blast the inventor divides the converter into two compartments, one being the main reservoir for the metal, and the other and smaller one for the process of conversion. The metal flows from all parts of the larger chamber to the smaller during the process of conversion. In one form of this converter, where the blast is admitted vertically from beneath, the converting chamber is a short tube, placed in the converter with its axis coincident with the blast of air. The lower end of this tube or cylinder is a short distance off the bottom of the converter, so that the blast of air as it proceeds upwards blows the metal in the tube over its top edge, whilst a fresh supply passes in from the lower part of the converter under the lower edge of the tube. Nine claims are made.—No. 10324. June 25th, 1889. 8*d.*

BOOT MACHINERY.—*J. W. Sharp, Kettering, Northamptonshire.*—This improved machine is for forming rands or split lifts to a required shape for use in making heels for boots and shoes. Referring to the illustrations, Fig. 1 represents a front elevation of the improved machine, Fig. 2 a broken plan, and Figs. 3 and 4 enlarged details. To the frame A is cast a cylindrical box or inside former E. In this box is the disc D, carried by the

FIG. 1

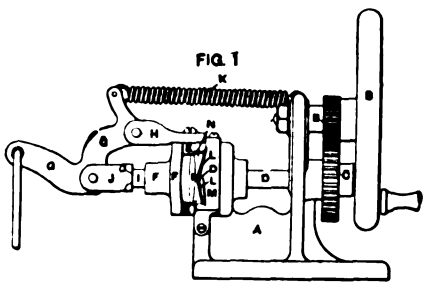


FIG. 2

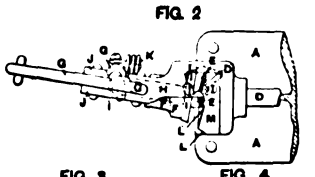

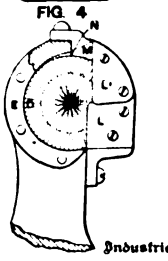

FIG. 3

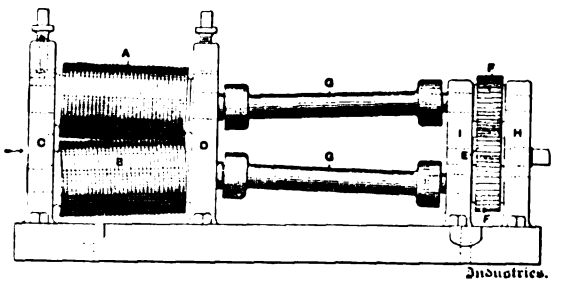

FIG. 4

spindle D and rotated by the gear and hand-wheel B. Facing the disc D is a second disc I placed at an angle to suit the bevelled face of the disc D. The disc I is secured to a spindle not free to rotate, but having a horizontal sliding motion which may be imparted to it by the operator pressing down the lever G. The lever G is normally held up and the discs apart by the spring K. The operation of the machine is as follows: The machine is first put in motion; the splits or rands being then placed between the two discs on to guard L are then firmly gripped by the operation of the lever G and pass round inside the cylindrical box or inside former to opening N and on to guards M and L^1. Claims: (1) The peculiar form of the cylindrical box or inside former E as illustrated; (2) the combination of cylindrical box or inside former discs and guards as shown in the accompanying drawings; (3) the combination of discs I and D as shown in Fig. 2, discs I being thrown out of line with disc D as herein described and illustrated in the accompanying drawings; (4) in combination with sliding and revolving discs the application of bell cranks or levers for the purpose of giving a firm grip to the material during the operation of the machine.—No. 5818. April 5th, 1889. 6*d.*

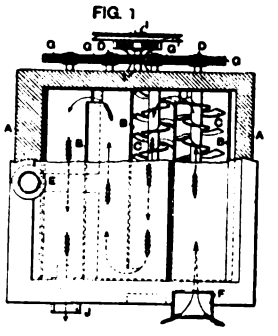
HYDRAULIC MAINS FOR GAS.—*N. Meiklejohn, Longwood, Huddersfield.*—Reference is made to the dip pipes of hydraulic mains. In the hydraulic main, an alternate thoroughfare is provided in addition to the usual dip-pipe, for discharging the gas coming through the ascension pipe. This thoroughfare is situated above the level of the water, and is opened and closed by means of a slide valve. When the alternate thoroughfare is closed, the gas is compelled to seek an exit by the dip-pipe and through the water in the usual manner, while when the alternate thoroughfare is open the gas passes through it directly to the hydraulic main without passing through the water. Normally, the alternate thoroughfare is opened and the gas passes through it, but when the retort is recharged it is closed, and the gas made to pass through the water. The slide valve may be operated by connecting it to the retort lid, so that the act of opening the retort closes the slide valve. Three claims are made.—No. 11456. July 17th, 1889.

MANUFACTURE OF METALLIC TUBES.—*C. Faulkner & W. E. Lloyd, Birmingham.*—The machine consists essentially of three horizontal rolls driven in the same direction and at equal rate. The illustration shows a side elevation of this machine. The three nearly horizontal rollers A, B, C are driven by the four pinions E, F, F, F carried by the housings or standards H, I; the pinion E being the driving pinion. The shafts of the rollers and the shafts of the three pinions F are coupled together by the rods G. The face of each roller has a helical or spiral groove formed in it as represented, and the rolls slightly converge towards the housing D. In using the machine represented the tube is formed from a hollow ingot or short thick hollow cylinder supported internally by a fixed mandrel, by introducing it between

the rolls endwise or in the direction of the arrow, that is, between the rolls at their widest ends, or the ends at which the distance between them is greatest. By the rotation of the rolls, the tubular ingot, introduced between them, is made to rotate, and by the action of the helical or spiral grooves on the acting faces of the rolls is drawn into and carried through the machine. The hollow ingot is thereby lengthened and its external diameter reduced. The tube may be passed several times through the machine according to the length and external diameter required, the tube after each rolling operation being heated and the upper roll or all the rolls being readjusted. The tube thus produced has a helical or spiral groove on its exterior which is removed either by the ordinary rolling or drawing process or by making the surface of the rollers plain at the finishing ends. Claim: Combining a series of rolls slightly inclined to one another, one or more of the said rolls having on its or their acting surface or surfaces a helical or spiral groove or grooves, the said rolls and their driving mechanism being constructed and arranged substantially in the manner hereinbefore described and illustrated in the accompanying drawings, so that the hollow ingot or short thick tube to be operated upon may be introduced between the rolls endwise at the ends of the rolls most distant from one another, the said hollow ingot being made by the action of the rolls to rotate, its external diameter being reduced and its length increased, and delivered from between those ends of the rolls opposite to the ends at which it had been introduced, the advancing motion of the ingot or partly made tube being effected by the helical groove or grooves on the roll or rolls, substantially as described and illustrated.—No. 8496. May 22nd, 1889. 8*d.*

DRYING SUBSTANCES.—*P. Cornish, Jun., Leyton, Essex.*—This invention is devised primarily with the object of removing the moisture from such materials as contain a considerable quantity, such as the residual matter arising from the chemical treatment and pressure of fœcal sludge and the like at sewage works; and thus, by means of the invention, to convert into a valuable manurial base what would otherwise, owing to the large percentage of water contained in it, be a comparatively useless substance for manure. The apparatus employed is illustrated, Fig. 1 being a plan and Fig. 2 a side elevation. It consists of a number of metal troughs B, arranged step-like in a specially constructed brick furnace. One end of each trough communicates with the trough above and the trough below it. In the troughs are helical propellers C, whose spindles D are geared to each other by wheels G, and the whole rotated by a V-grooved pulley I. The matter to be desiccated is placed in the hopper F, from whence it flows to the top trough. From the top vessel it is propelled by the helical propellers to the bottom

FIG. 1



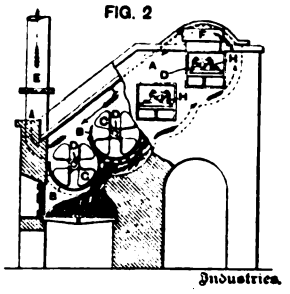


FIG. 2

vessel, whilst the heat from the furnace playing upon the under parts of vessels gradually evaporate the moisture. The moisture evaporated passes off with the fumes from the furnace, as indicated by the arrows. Claims: (1) The improved means for drying or desiccating substances or materials substantially as described and shown; (2) in the improved means for drying or desiccating substances or materials, the combination of cylinders or troughs heated in the manner described, and the arrangement

Digitized by Google

employed for conveying the materials or substances alternately through each cylinder or trough in opposite directions substantially as herein set forth and shown and for the purposes specified.—No. 6102. April 9th, 1889. 8*d*.

Screw Propellers.—*T. Fisher, Holywood, Down, Ireland.*—To facilitate the motion of propeller blades in the water the inventor lubricates them in the following manner: A tubular duct leads from the cavity of the boss to the leading edge of the propeller blades. The cavity of the propeller boss is filled with lubricant so that it flows from the boss above the leading edges of the blades, and issues from them through small perforations. The oil is supplied to the boss from a reservoir within the vessel, through a hole in the centre of the shaft. Claims: (1) The use in steam ships of a screw propeller arranged with blades having perforated channels or tubular ducts constructed and employed in the manner and for the purpose described; (2) the use in steam ships of a bored screw shaft arranged with a gland and stuffing box and an oil pipe or conduit, constructed, connected, and employed in the manner and for the purpose described; (3) the combination and arrangement of parts constituting the improved lubricating apparatus, constructed, connected, and employed in the manner and for the purposes described.—No. 3330. March 3rd, 1890. 6*d*.

ELECTRICITY.

Carbons for Electric Lamps.—*H. H. Lake, London.* (*Lacombe & Co., Paris, France.*)—A description of the invention is given in the following claims: (1) A carbon or electrode composed of plates or discs of carbon arranged side by side and having between them a steadying substance or composition, the whole being united by pressure; (2) the improved method of manufacturing carbons or electrodes for electric arc lamps, consisting in first slightly compressing carbon mixed with a suitable binding or agglutinating material, and thus forming one of the elementary discs or other pieces, then covering one side of the said disc or other piece with a layer of the steadying substance and placing thereon a second disc or other piece prepared in the same manner as the first, and then subjecting the whole to heavy pressure and baking it; (3) the improved method of manufacturing carbons or electrodes for electric arc lamps, consisting in placing in a suitable mould, a layer of carbon mixed with binding or agglutinating material, covering this layer with the steadying substance or composition, and placing thereon a similar layer of carbon, and then uniting the whole by pressure or otherwise; (4) a cylindrical or other carbon or electrode having the steadying substance or composition extending helically around the same; (5) the method of manufacturing carbons and electrodes for electric lamps, consisting in forming a spiral or coil of carbon, extending the same longitudinally, placing between its convolutions the steadying substance or composition, and then effecting an intimate union between the convolutions and the steadying material by pressure or otherwise.—No. 9133. June 1st, 1889. 6*d*.

Automatic Switch for Accumulators.—*M. E. Unger, Berlin.*—The switch is used in charging electric secondary batteries in series for the purpose of transferring the electric current from one series to another. A disc of insulating material is mounted on a shaft revolving in bearings. Around the disc are a set of metallic coatings corresponding to the number of connections to be made. The coatings are insulated from one another step like on the disc, their number being one more than the number of series. On the disc there are also places not coated with metal corresponding to the several segments. The contact pieces are passed over and consecutively rubbed by springs in communication with the source of electricity, and which conduct the current to the metallic coatings. From the metallic coatings proceed short metal strips in connection with contact rollers fixed insulatedly on the shaft of the disc. The rollers rotate in quicksilver in vessels insulated from one another, but in connection with the poles of the series. The uncoated parts of the disc serve upon the sliding off of the springs to interrupt the current from the contact surface in connection with the last negative pole of the series, until upon the further turning of the disc a spring once more comes in contact with a contact surface in connection with the negative pole of the corresponding series, so that by this means short-circuiting between the poles of the secondary batteries is prevented. Two claims are made.—No. 8030. May 14th, 1889. 6*d*.

Supporting Electric Conductors.—*W. A. S. Benson, London.*—The inventor binds together the insulated conductors forming part of an electric circuit by a wire wound spirally around them. This gives the conductors an ornamental appearance and lessens the risk of injury. If the conductors have to take a longitudinal stress, wires are laid parallel to them and bound together with them. The conductors are attached to walls, &c., in the following manner: Over the conductors is passed a tube, which is screwed upon the outside. This tube is slotted to receive the longitudinal supporting wires and the end of the protecting wire. The wires are turned over into the slots from the inside of the tube, and the tube is then screwed into a receiving socket attached to the walls. Claims: (1) In a support for electric conductors the combination of a spirally wound wire or wires enclosing the conductors with a longitudinal wire or wires for taking the end stress: (2) in a support for electric conductors the combination of a spirally wound wire or wires enclosing the conductors with a longitudinal wire or wires for taking the endway stress, the ends of these wires being held by an inner tube on which is screwed an outer tube or socket.—No. 7796. May 9th, 1889. 6*d*.

Arc Lamps.—*G. Hookham, Birmingham.*—In the simplest form of arc lamp constructed according to this invention the feed mechanism is actuated by the weight of the upper carbon and the carbon-holder. The descent of this weight is retarded by the eddy-currents generated in a Foucault disc, to which the weight is connected by multiplying gear. It is so arranged that when the current and e.m.f. are normal, the rate of approach of the carbons is approximately that required to maintain the current and the e.m.f. at their normal values. If C represents a circuit carrying the main current, and E a circuit formed by a shunt between the terminals of the lamp, then the Foucault disc may be retarded by two magnets, one whose magnetising force is proportional to C − E and the other to C + E. The C + E magnet may clamp the disc, and so stop the feed when the E C exceeds the normal. In practice, however, the current supplied to lamps is approximately constant, and in this case a single magnet producing currents in the disc will suffice. In a lamp constructed with one retarding magnet the disc revolves between the poles of the magnet through whose coils the main circuit passes. A second magnet in a high resisting shunt circuit operates a catch, which locks the disc when the lamp is not at work, and so prevents the disc racing. A third magnet in the main circuit acts upon the lower carbon-holder, and pulls it down against the resistance of a coil spring to strike the arch as the current passes across the carbon. Claim: In an arc lamp the construction and arrangement of parts whereby the feed of the carbon is regulated by the increase or decrease of electrical currents generated in a metal disc as described.—No. 6578. April 17th, 1889. 8*d*.

Primary Batteries.—*R. A. Burnell, London.*—The battery is constructed upon the principle of the Leclanché batteries, in which the electrodes consist of zinc and carbon and the exciting liquid of a solution of sal-ammoniac. In the present invention, instead of surrounding the carbon with a mixture of granulated manganese and carbon, and hermetically sealing the porous cell, the carbon is made of a rifled cylindrical form and with a hole extending from the bottom to the top. In the grooves of the carbon are placed porous sheaths filled with granulated unheated manganese. In one of these grooves is placed a zinc rod forming the zinc electrode. The zinc is insulated from the carbon by a glass sheath, and clears the bottom of the vessel. The porous sheaths and zinc rod are held firmly to the carbon by surrounding bands. The battery is completed by partially immersing the part above described in a vessel containing the exciting fluid. By this construction the manganese comes into direct contact with the exciting liquid, and also with the atmospheric air, so that the hydrogen generated is at once absorbed by its oxygen. The sheaths can also be easily removed and filled with fresh manganese. Claims: (1) A Leclanché battery in which the carbon for increasing the surface is made of a hollow body, which is parallopipedic, or provided with longitudinal grooves upon the outer surface of the said body being imbedded, the porous sheaths filled with unheated granulated manganese, and the rod of zinc that is separated by a non-conductor from the carbon in such a manner that the sheaths are in direct contact with the atmospheric air, and the electrolyte, for the purpose of bringing the hydrogen generated in contact with continually renewed oxygen, so as to impart to the battery a great durability, and obtaining on the other hand with the least space and weight an increased electromotive force and convenient accessibility; (2) the modification of a Leclanché battery, in which the zinc electrode surrounds the carbon electrode with the filling of manganese like a casing, a layer of insulating material adapted to allow the passage of the exciting liquid being inserted, and that, if necessary, it is provided with holes and tightly surrounded by a layer of insulating material impregnated with the exciting liquid, for the purpose of converting the battery into a dry battery.—No. 6410. April 15th, 1889. 8*d*.

CHEMISTRY.

Extracting Precious Metals from Ores.—*R. L. Cousens, Johannisberg, South African Republic.*—In the first place the ore is pulverised, and the resulting powder passed between or over magnetised iron rollers, so that the magnetic constituents, such as iron, are eliminated, as these matters adhere to the rollers, and may be collected. The ore powder freed from iron is then put into a strong wooden barrel mounted upon metal trunnions. A quantity of salt and lime is added to the powder, and the whole is moistened by water. The barrel is then closed and revolved, whilst a current of electricity is transmitted through the contents.

FIG. 1

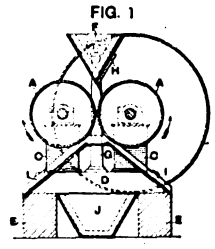

FIG. 2

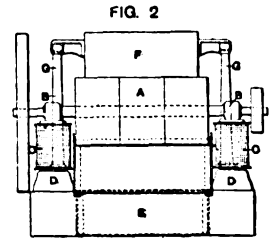

FIG. 3

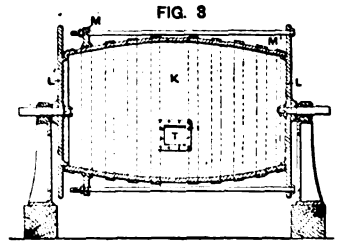

FIG. 5

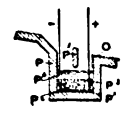

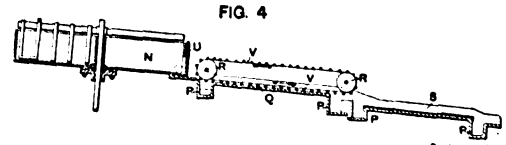

FIG. 4

Industries.

After a time mercury is introduced into the barrel, and the revolution continued. The mixture is next run into a receptacle, and, after being agitated, is delivered to an electrolysing vessel. In the accompanying illustrations, Figs. 1 and 2 show the magnetised rollers. Their bearings C are the poles of electromagnets, which have the effect of magnetising the rolls with opposite polarity. The powdered ore is fed into the hopper F, and falls down between the rollers A, which revolve in the direction of the arrows. The structure of the wooden barrel will be readily understood from Fig. 3. After the treatment of the ore in the barrel, it is fed to the circular receptacle N, in which works a rotating rack. From N it flows to the electrolysing vessel P (shown enlarged in Fig. 5). The vessel P is made of wood, and has at its bottom a copper plate P^1 connected to the terminal of a dynamo. On the plate P^1 is a layer of sand P^2, moistened with acid and covered by a porous diaphragm P^3. On the diaphragm is a layer of mercury, which is connected to the terminal of the electric generator. A partition P^5 extends down nearly to the mercury, so that the material as it flows down the vessel has to pass under the partition in close contact with the mercury. From P the material flows over a sheet of copper Q coated with mercury, and having a series of rubbers V, faced with flannel, travelling over its surface. The plate Q and the rubbers V are connected to the different poles of a battery. After leaving the plate Q the tailings pass through two or more electrolysing vessels P like that above described, and then over a woollen or felt blanket S, between a lead plate below it and a copper plate above it, these plates being connected to opposite electrical terminals. The tailings that flow from the blanket may be passed through a final electrolysing vessel P or through several of these in succession. The amalgam collected from the vessels P, the plate Q, and the blanket S, is distilled in the usual way. Claims: (1) The herein-described process for extracting precious metals from ore or quartz by crushing the material, clearing the pulverised material of the magnetic constituents by passing it between magnetic rolls, effecting amalgamation under electric action in a revolving barrel, and passing the material through electrolysing vessels, over amalgamating surfaces electrically cleansed, and through a blanket subject to electric action; (2) the magnetic rolls constructed and operating substantially as described with reference to Figs. 1 and 2; (3) the amalgamating barrel K constructed and operating substantially as described with reference to Fig. 3; (4) the construction and arrangement of the electrolysing vessel P substantially as described; (5) the combination of the agitating vessel N, the mercury-coated plate Q with its rubbers V, the blanket S with its enclosing plates, and several electrolysing vessels P, constructed and arranged substantially as described with reference to Fig. 4.—No. 8608. May 23, 1889. 8*d*.

Colouring Matters.—*O. Imray, London.* (*The Farbwerke Vormals Meister, Lucius & Brüning*).—This invention relates to the manufacture of a blue violet colouring matter unknown up to the present time, the hydrochlorate of which is soluble in hot water, and has the composition $C_{24}H_{18}N_4HCl$. The colouring matter is obtained by heating a mixture of five parts of aniline, 3·9 parts of hydrochlorate of aniline, and two parts of amidoazobenzol. A compound is thus produced which contains the said colouring matter, and from which it can be separated by the following means:—The compound, which contains a mixture of indulines, is boiled twice or thrice with a large quantity of water and filtered; hydrochloric acid is added to the reunited filtrates, whereby the whole of the new colouring matter is precipitated, together with other indulines in the form of hydrochlorates. This mixture is collected on a filter, pressed and dried at a temperature of from 70° to 80° C. The process for the separation of the new colouring matter from the above-mentioned mixture is founded on the fact that, of all the colouring matters which form in the mixture, the new colouring matter alone is capable of forming a stable acetate. The mixture of the hydrochlorates of the indulines is for this purpose mixed with diluted soda lye for from twelve to twenty-four hours; the induline bases thus obtained are then collected on a filter and washed carefully with cold water. The mixture of the bases, in a still wet state, is suspended in 100 to 150 parts of water; acetic acid is added and the whole is boiled, when the new induline $C_{24}H_{18}N_4$ will dissolve. It is filtered hot, and the filtrate is evaporated to one-fourth of its volume, when the acetate of the induline $C_{24}H_{18}N_4$ will crystallise, forming blue leaflets with brown lustre. It is collected on a filter, pressed, and dried at 80° C. The acetate thus obtained is easily soluble in cold water, and is a colouring matter very valuable for dyeing and cloth printing purposes. Claim: The described manufacture of salts of the induline base which are soluble in water.—No. 7857. May 10th, 1889. 4*d*.

MISCELLANEOUS.

Signal Bells.—*J. Hall, Swadlincote, Derbyshire.*—Means are here described for actuating the striker of alarm or signal bells used in engine-rooms, railway signal-boxes, &c. The striker is attached to the vertical arm of a bell crank lever, which is pivoted at its angle, and whose other arm is horizontal and weighted. In its normal position the striker is just held clear of the bell by a pin against the vertical arm of the bell crank lever. The arm carrying the striker is made of sufficient flexibility to strike the bell once when the lower arm is raised a certain distance and suddenly released. To raise the lower arm a lever pivoted at one end to the frame, and having at the other a knuckle-jointed finger, is caused to partly revolve upon its pivot and its finger to strike and lift the arm. After the arm has been raised a certain height, the finger slides out of contact with the end of the arm, and the latter thus falls, and the bell is struck. The lever carrying the finger is operated by a slotted bar, to which a longitudinal motion is given by the operator. A pin in this bar slides in a slot in the finger lever. The knuckle joint of the finger enables it to pass over the end of the lower arm of the bell crank lever when the parts resume their normal positions. Claim: The combination of parts as described, forming an apparatus for actuating the hammer or striker of an alarm or signal bell.—No. 9274. June 4th, 1889. 6*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

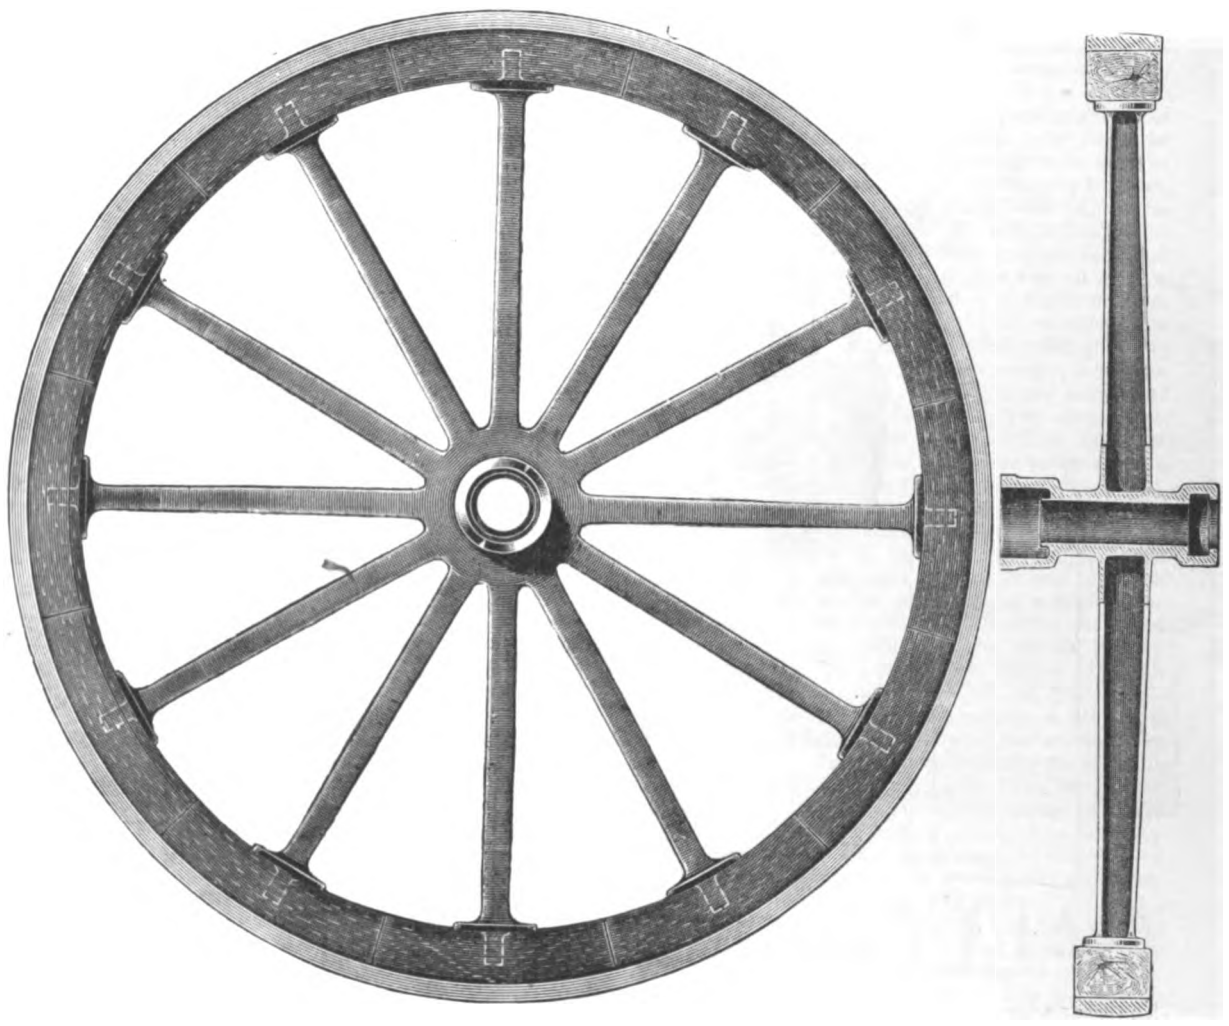
AN IMPROVED ROAD WHEEL.

We illustrate herewith in elevation and axial section an improved form of road wheel invented by Mr. Claude Carter, Levenshulme, near Manchester. The arms and nave are of cast steel in one piece, and the ends of the arms have soles cast upon them, to which the wooden felloes are attached. Each felloe is thus given a much better support than is usually the case, and it is prevented from being so readily splintered. An iron hoop is shrunk over the felloes in the usual way. The wheel is not dished, as is the case with wooden ones, but on the contrary the tyre is perfectly cylindrical. An advantage in it is that the expansion and contraction of the arms and hoops will be practically equal, and the shrinkage will not produce the loose fitting so often noticed in wooden wheels in warm, dry weather. The chief feature is found in the strength obtained with a weight not exceeding and in some cases less than that of the ordinary type. As the arms are entirely free during the process of casting, no initial strains are set up.

THREE MODERN PROFESSIONS.

At the recent graduation ceremony at Edinburgh University, Professor Masson delivered an interesting address to the graduates, in which, among other things, he pointed out that the three great old professions of the Church, Law, and Medicine are not now the only employments entitled, by the dimensions they have assumed in the body politic, to the distinctive name of "professions." There have sprung up among us at least three other professions, competing with the three older, namely, Teaching, Journalism, and Engineering; and on each of these he gave some useful advice.

He spoke of teaching as a new profession, for it is only within recent years that it has become an independent part of the public service, having previously been to a great extent a kind of dependency of the Church. It is now organised and graded very thoroughly and definitely, and more than ever demands higher and more varied qualifications. Journalism had made more rapid advances than even teaching. What with the effects of the telegraph and the telephone on communication, added to those of steam navigation and the railway on locomotion, there never was a time in the history of the world when what may be called the throb of the present was so feverishly felt. To stimulate and maintain this fever of interest, what an abundance we have now of newspapers, and what an army of men are now enlisted in their service! Professor Masson pointed out, moreover, that the applications of the physical sciences to modern industrial purposes had not been sufficiently recognised by the Universities. He mentioned, what we have very often stated to our readers, that in Germany there was hardly a great manufacturing or mining establishment but has a staff of highly trained chemists or other scientific experts attached to it, applying their theoretical knowledge to the practical exigencies of the processes they superintend, suggesting improvements and simplifications, and amply repaying the cost of their salaries by the economies which they effect.



It would seem to be in Scotland that the first systematic attempt to organise engineering education on anything like a complete basis is to be made. At present a Commission is sitting for the purpose of reconstituting the Scotch Universities, and bringing them more in harmony with the wants of the times, and the members are being flooded with suggestions of all kinds. Unfortunately engineering is not directly represented on the Commission, and there is therefore the more necessity for those who are interested in the matter to do all they can to impress their views on the Commissioners. Fortunately this is being done.

We lately received a copy of a paper on "A University Faculty of Engineering," read by Mr. Henry Dyer before the Institution of Engineers and Shipbuilders in Scotland, in which the requirements of the different departments of the profession are forcibly pointed out. We also observe a paper by the same author in the *Scots Magazine*, and it is quite evident from these papers that events in Scotland are shaping themselves very much in the direction which Mr. Dyer has frequently indicated in our columns; in fact, all the main principles for which he has been contending seem to have been conceded, and all that is now required is the filling up of details and furnishing the necessary appliances.

Mr. Dyer takes the enumeration of the different sections of the profession of engineering which was given by the Council of the Institution of Civil Engineers some years ago, and points out that the whole field is fairly well covered by the following group of practically distinct professions:—(1) Civil Engineering; (2) Mechanical Engineering; (3) Naval Architecture; (4) Electrical Engineering; (5) Architecture; (6) Chemical Engineering; (7) Metallurgy; (8) Mining Engineering; and he advises that complete courses of instruction should be given in each of these departments. As a matter of fact, this is already done in fully equipped technical colleges on the Continent and in America. In this country the tendency is rather to extend the existing science faculties by having a department for applied science or engineering. In the second paper by Mr. Dyer, to which we have alluded, he proposes that there should be a faculty of science, which, with the classes in colleges affiliated to or recognised by the University, or with those conducted by recognised University teachers, will embrace the main departments of general and applied science; and he points out that, as Glasgow is the centre of the most important engineering works in the world, it might also soon have the most complete school of engineering. He claims for the various departments of engineering a place amongst university studies, not only because of their immense importance in our present state of civilisation, and therefore deserving the highest culture and training the Universities can afford, but also because of the good general education and of the preliminary training in pure science which they require of those who would successfully pursue them.

For engineers and manufacturers generally, mere technical skill and knowledge are of little use unless they are accompanied by manly spirit and enthusiasm, and even these will not tend to the greatest good unless combined with depth of social spirit. An engineer's general education should therefore include, in addition to the ordinary subjects, a knowledge of existing political institutions in Britain, both local and central, and this should be obtained by a historical study of their development and of the political ideas therein involved. In addition, however, to the more general subjects, the historical development of the different departments of engineering might be made a most valuable means of developing the minds of the students, by showing the influence they have had on the advancing civilisation of the world. The most instructive and interesting, and ultimately the most useful, method of studying any subject whatever, is the historical, and in none could it be made more interesting and instructive than in engineering. It would not be a mere case of collecting facts, figures, and formulæ, all in a cut-and-dried shape, ready to be poured on an examination paper, but would give the students a living interest in the subject. In what, for instance, is usually called civil engineering, the development of roads, railways, canals, harbours, lighthouses, &c., might be traced from the earliest periods to the present time, with the side lights they threw on the lives of the people and their several habits. The history of mechanical engineering is bound up with that of the great industrial revolution which has changed the face of the globe, and the methods of carrying on almost every department of work. The study of the effects of these on economic and social conditions should be an essential part of the education of all mechanical engineers. In naval architecture the development of ships of all kinds, the effects of improved navigation on the trade and commerce of the world, would afford a similarly interesting field for historical, economic, and social studies. Electrical engineering, which has shrunk the globe to insignificance and has levelled the inequalities of commerce, and promises to again revolutionise our industrial system, opens up many fields both for economic inquiry and speculation. Architecture, from an historical point of view, is simply the manners and customs and ideas of the people built up in wood, brick, or stone. The applications of chemistry and metallurgy, which have been the means of utilising substances formerly thought useless, and have afforded work and subsistence to large bodies of the people, have had an immense effect on social conditions, while mining in all its departments has afforded the raw materials for many of the arts and manufactures. Moreover, engineering is entitled to a place among liberal branches of education on account of the training in pure science required of those who practise it. All engineers should have a fair knowledge of mathematics. Not necessarily, as Mr. Dyer remarks, such a knowledge as would secure them a high position in such phantoms as mathematical triposes or other University honour lists, but a real knowledge, which would not only train their intellectual powers, but also fit them to solve the problems which they meet in everyday life. They should also have a fair knowledge of French and German, and at least of one general subject—such as literature, history, and political economy—so that they may be able to rise out of the narrow groove of scientific and professional interests.

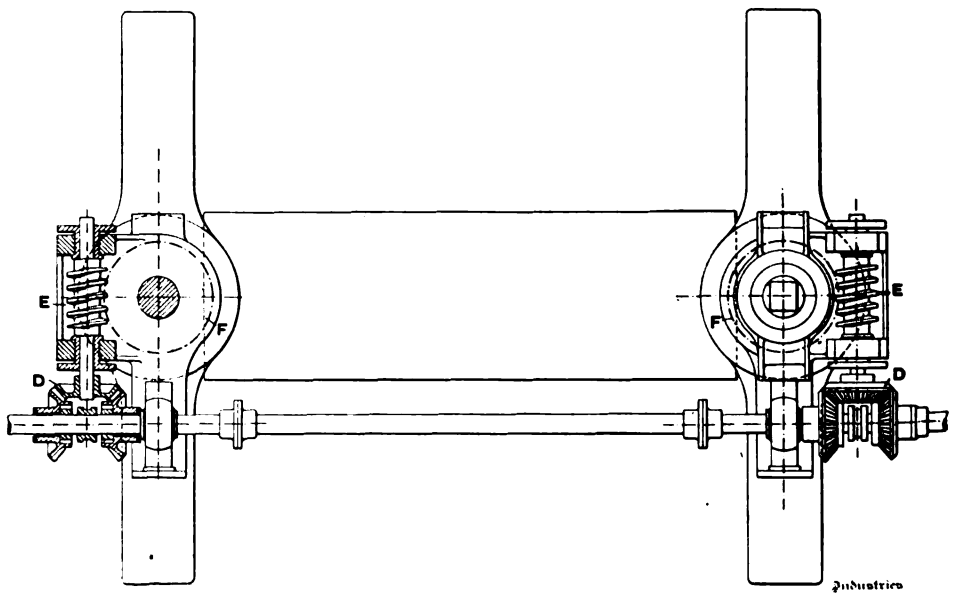
JARDINE'S HOUSING GEAR FOR ROLLING MILLS.



CONSTRUCTED BY MESSRS. GRIEVE & CO., MOTHERWELL, NEAR GLASGOW.

END ELEVATION.

FRONT ELEVATION.

PLAN, PARTLY IN SECTION.

The arrangements made by the students for obtaining a knowledge of the practical parts of their profession will, to a large extent, depend on their private circumstances and opportunities. Some may enter the university or technical college on leaving the secondary school, and take what practical work they can during the recess, and complete their apprenticeship at the end of their university or college course; some, on leaving school, may go direct to the workshops and attend classes in the evenings, and when they have finished their apprenticeship they may go to the day classes for a session or two; while others may try a combination of the two systems.

We feel convinced that if the proposals made in Mr. Dyer's two papers be carried out, not only will there be ample opportunities for the specialised study of pure or general science, but further, the newer professions which have arisen during recent years from the great development of manufactures will be placed in the same position as regards training as the older professions. We are pleased to observe that Mr. Dyer attaches so much importance to the social aspect of engineering education. He points out that every social improvement must have its foundation in an improvement in education, and that the welfare of the producers, be they employers or employed, and not simply the cheapness of the products, the organisation of capital and labour, the arrangement of all disputes by reason and not by force, are the great problems of the future, and their solution will demand the best efforts of our noblest men.

JARDINE'S HOUSING GEAR FOR ROLLING MILLS.

HITHERTO, the manipulation of the large housing screws for adjusting the upper roll of rolling mills has usually necessitated the employment of four men, two to each screw. By means of the gear, which we illustrate above, this manipulation can be easily performed by one man. The gear has been patented by Mr. John Jardine, 108, Windsor Terrace, Motherwell, N.B., and is being made by Messrs. Grieve, of the same town. As will be seen from the illustrations, showing a front elevation, end elevation, and plan, all partly in section, the action of the gear is very simple. The shaft A is driven continuously from any convenient source, and carries at either end a pair of mitre wheels B B, which run loose. Either wheel of these pairs may be driven at will by means of a special form of clutch C, which slides upon a feather in the shaft, and is actuated by a conveniently placed hand lever. A third mitre wheel D, on either side, and deriving motion from the wheels B B, actuates the worms E, which in turn transmit motion to the screws by means of the worm wheels F. The screws are also provided at their upper extremities with graduated brass index rings, by the aid of which a delicate adjustment can be effected. It is claimed that by the sensitive yet certain action of the clutches employed, the screws can be rapidly manipulated with the greatest nicety, that the slab is worked much quicker than by hand screwing, and that consequently the risk of breakage is reduced to a minimum. We are informed that this form of gear has been at work on a plate mill in Messrs. David Colville & Son's steelworks for upwards of nine months, and that this firm have decided to apply it to two new mills in course of construction by Messrs. Goodwin, Jardine, & Co., Limited, Motherwell.

THE IRON AND STEEL INSTITUTE.

(*Concluded from page* 447.)

A PAPER was afterwards read by Prof. W. C. Roberts-Austen, F.R.S., on "The Carburisation of Iron by the Diamond." It is universally recognised that the presence of carbon determines the physical properties of iron. It is, however, a singular fact that recent work, which has clearly shown the importance of the presence in iron of elements other than carbon, has in no way lowered the position which carbon holds as the element which confers upon iron the wide range of properties characteristic of steel. After an interesting summary of the historical experiments by which the true nature of steel was established, the author described Clouet's classical experiment, made in 1798, of melting a little crucible of iron containing a diamond, and obtaining a fused mass of steel. This experiment has been repeated by the author, using a vacuum instead of an atmosphere of gas. The use of the electric current rendered it pos-

Digitized by Google

sible to heat pure electrolytic iron in vacuo in the presence of diamond, and also to heat the iron itself before contact with the diamond is effected, and thus to deprive the iron of its occluded gas. The combination does not take place until a full red heat is reached. This experiment derives its theoretical interest from the assertion that no two elements can react on each other unless a third element be present.

The next paper which was read was by Dr. Edwin J. Ball, of the Royal School of Mines, on "The Changes in Iron produced by Thermal Treatment." The experiments described were made in 1884, and were not considered at the time sufficiently complete for publication, but in view of the researches of Osmond they have acquired new significance. No claim to priority is, however, in any way suggested. The author shows that changes in the magnetic capacity and tensile strength of steel, which occur at definite temperatures, may be made evident when the metal is rapidly cooled in water or in oil. The results are shown in the form of curves, and it is noticeable that in steel quenched at certain temperatures the changes both in magnetic capacity and in tensile strength are most distinct. The experiments consisted in heating pieces of steel to definite temperatures in a muffle, three pieces at a time. When the desired temperature was reached, one of the pieces of steel was rapidly removed from the muffle and plunged vertically into distilled water of a temperature of 15° C., the second was similarly plunged into oil of the same temperature as the water, and the third was allowed to cool slowly in air. In order to determine the temperatures, a pyrometric scale of metals of known melting-point was employed. The curves given by the author show that certain critical points are well marked. Two of these correspond with Osmond's; but the third is a new point, that has not been noticed by Osmond, whose experiments did not relate to so high a temperature.

In the discussion on these two papers, Mr. Snelus thought that it would be interesting to repeat Professor Roberts-Austen's experiment on a sufficiently large scale to enable the product to be analysed. He thought the carbon was dissolved in the iron, rather than in chemical combination. Seeing that diamond can be introduced into iron, he wondered whether the converse was possible. Dr. Ball's paper, he thought, threw light on the process of tempering, a process hitherto dependent on rule of thumb.

Dr. Ball, in replying to the discussion, pointed out that the critical point mentioned by Mr. Wrightson corresponded with his own.

Professor Roberts-Austen, in replying to Mr. Snelus, believed that, although the diamond could not be extracted from iron in the laboratory, the separation had been observed in certain meteoric irons.

The last paper dealt with on Wednesday was by Mr. F. Lynwood Garrison, Assoc.R.S.M., on "The Robert-Bessemer Steel Process." This paper was read at Paris in September, and was adjourned for discussion. The modification of the Bessemer process described was originated in 1884 at Stenay, as the Walrand-Delattre converter. It is elliptical in shape, having a flat surface, in which the tuyeres are always placed on the same plane parallel to the axis. It swings on trunnions, and the tuyeres are so arranged as to impart a rotary motion to the bath.

In the discussion which followed, Sir Henry Bessemer pointed out that sometimes a very small difference in a machine or process will produce highly advantageous results. He was disappointed to find, however, that in the Robert modification of his converter the difference likely to produce good results was wanting. Similar converters had been tried in his early experiments and abandoned. Rotation had been tried in Sweden. There was found to result a want of heat, and the metal could not be tapped; this was on account of the extreme purity of the Swedish iron. He had patented a vessel resting on axes in 1862.

On Thursday morning, the 8th inst., the proceedings commenced with Mr. W. J. Keep's paor on "Aluminium in Carburetted Iron." "Keep's tests" are relative, and are made on a test bar ½in. square by 12in. long, to show the strength of the metal to resist weight and impact, deflection set, and elasticity. They show where proportionality ceases, and give the rigidity, hardness, and shrinkage of cast metals. Rigidity is defined as the ability of a material to withstand stress and retain its original form, and its diagram follows the curve of the tests up to the limit of proportionality, after which point elasticity and set are recorded. Elasticity is the property possessed by matter of regaining its shape after distortion. The diagram of a test records the elastic deflection and the set deflection, and, by removing the effect of the former, a diagram of rigidity is obtained. The author considers the influence of aluminium on iron, as shown by a stress of 200lb., and for impacts of a fall of 1¼in., ten blows having been struck from a ⅛in. fall up to this blow. Tabulated results of a large number of experiments are given to show the effect of aluminium alone, and of the modifying influence of carbon from ¼ per cent. up to saturation. Aluminium diminishes deflection in Robert-Bessemer ingot iron by decreasing the set and elasticity; the rigidity is increased, the grain is closer and more uniform, and the metal is improved in every way when considered as a structural material. Aluminium softens iron whether it contains carbon or not. Wrought iron with 2·45 per cent. of aluminium welds well, and can be bent nearly double when cold, and can be melted and cast nearly as easily as cast iron. Where carbon is low, aluminium does not change it into graphite, but drives out some of the existing graphite. Its action on white cast iron is to decrease the total carbon and change part of the remainder into graphite. The rigidity and elasticity are accordingly increased, while the hardness is decreased. The rigidity of grey cast iron is not affected, but other effects are similar to those in white iron. As a structural material, therefore, iron is improved, but the use of aluminium is not advocated under existing conditions. If grey cast iron could be produced by aluminium instead of silicon, with no increase in cost, such metal would be better for most purposes. Even at its present price aluminium can be used with great advantage, especially on ingot iron caught directly from the converter.

In the discussion which followed, Mr. J. Riley stated that he had tried to use aluminium several times, but he did not find its effect so good as is generally believed, and, accordingly, its advantages do not compensate for its extra cost. He attempted to use it in order to reduce the melting point, so that cracks and ruptures in ingots and castings, incidental to hot casting, might be eliminated. The influence in this direction was very considerable, but a fresh defect was introduced—the metal solidified more quickly. This was especially noticeable in the case of an alloy made from 20 per cent. of second quality aluminium and 80 per cent. of steel. By analysis this alloy contained 18·30 per cent., and had a specific gravity of 6·23. It was very fluid at a full heat, but it set so rapidly that only half could be poured from the crucible. The same effect is marked with 3½–4½ per cent., and is even noticeable with 2½ per cent. The tensile strength is increased some two or three tons, but the elastic limit is raised considerably, and there is some addition to the ductility. If it could reduce the heads of castings by even 25 per cent. it might be economical, but Mr. Riley came to the conclusion that it could only be used succesfully for small, thin, light, or intricate castings. In large charges the effect of the aluminium seems to be dissipated. In making alloys, the use of this metal is of great importance, as it renders alloys of copper and iron homogeneous, and a similar effect was noticed with a nickel iron alloy.

Mr. Spencer, of Newcastle-on-Tyne, agreed with the previous speaker, and thought that the value of aluminium would be less when the carbon contents were increased. It could only be successfully used in the case of Mitis or similar castings.

Sir Lowthian Bell stated that in making aluminium-copper alloys there appeared to be a true chemical combination, as the temperature rose considerably when the aluminium was introduced.

Mr. Allen said that analysts rarely looked for aluminium. Most likely Dr. Percy's strong opinion on this point had had something to do with this. But nevertheless, aluminium, like titanium, often exists in pig iron, though probably it rarely occurs in steel or wrought iron. It may be put into the metal, but it is often a question whether it stops there.

Mr. E. Riley inquired whether aluminiun combined with oxygen in the metal; in this case it would disappear into the slag, but would at the same time improve the material. It had a similar effect in aluminium copper alloys.

Mr. Stead had never failed to find at least traces of aluminium in metal to which it had been added, and he considered it quite possible for the alloy of iron and aluminium to exist. Any oxidising influence would tend to remove it, but some of the alumina might be mechanically entangled in the steel, and it was difficult to differentiate between alumina and aluminium in the analysis. In any case the analysis of alumium steel is difficult, for potassium hydrate will not separate traces of alumina from ferro-hydrate. A remarkable property of aluminium iron alloys is the expansion and consequent lowering of the specific gravity. An alloy of 2·6 parts of aluminium and 7·8 parts of iron expands 6·8 per cent.

Mr. Hadfield questioned whether aluminium really reduced the melting point of iron. The effect might be due to the oxidation of aluminium, which has a higher calorific power than silicon, or the apparent difference might be due to the greater fusibility of the slag. An experiment had been made with an alloy containing 5 per cent. of aluminium and no carbon, and the melting point was estimated at about 1,475°, as compared with 1,500°, the melting point of steel.

Mr. Galbraith thought that the loss of aluminium may decide the question of the cost. The metal is certainly found in pig iron, but in the case of Mitis castings it probably only acts on the oxide present. Mr. Keep, in one of his tables, had only given the estimated aluminium; so in this case, at least, there was no certainty that it was really present.

Mr. Galbraith proceeded to read a paper on "Certain Chemical Phenomena in the Manufacture of Steel." Difficulty is often experienced in the manufacture of soft steel in the Siemens or Bessemer process, especially when using basic lining, in keeping the metal quiet in the moulds and also in teeming it. It occasionally gets cold and sets in the ladle, and this is most likely to occur when the metal is "wild." In order to be able to ascertain the cause, and, if possible, the remedy for this, the following facts should be considered:—(1) The difficulty in teeming is *not* due to any lack of heat—*i.e.*, in such a case there has probably been as much heat put on the furnace as it could bear; (2) the slag in such a case invariably contains a large excess of oxide of iron, and is blacker and more metallic in appearance than usual; (3) there is an enormous evolution of gas; (4) there is a larger consumption of spiegeleisen or ferro-manganese than usual before we can get any additional carbon in the steel. The first fact has often been noticed, especially when the slag is thin. It is, of course, absurd to suppose that the mere presence of a "thin" slag can influence the fusing point of the metal, and it is preferable to suppose that the slag, containing an excess of oxide of iron, oxidises the metal so rapidly and so effectually that it becomes charged with an oxide of iron; that this oxide of iron is one of those lower oxides likely to be produced at a high temperature, and is almost absolutely infusible; and that when the slag is non-oxidising the metal is free from these oxides, and hence more fusible. If such a lower oxide can be formed at all, all the conditions of its formation are present, namely, a very high temperature, a very oxidising basic slag, and a very large excess of the metal. In the basic-Bessemer process the consumption of spiegeleisen is greater than in the acid process, and if the slag contains a large excess of oxide of iron, the metal is wild and infusible. The difficulty in making steel ship plates is attributed to this fact of the varying consumption of spiegel or ferro-manganese, due to the character of the slag. The heat will not teem; it will be "cold"; if the slag is black and metallic, the loss of spiegeleisen and metal is then greatest. The same difficulty is met in the basic-Siemens process. The author knows of no serious attempt in this country to make hard steel by the basic-Siemens process by *means of additions to soft steel;* this can only be successful if the slag is thoroughly non-oxidising, or, better still, by removing it, and proceeding as described later on. Occluded gas from basic steel contains more carbonic oxide and less hydrogen than gas from other steels. This may be explained by the existence of the oxides above referred to. Indeed, the extra absorption of carbon in the basic process, and the liberation of the extra quantity of carbonic oxide, are about the only evidence that can be adduced as to the presence of these oxides in the molten metal. These is another disadvantage in having too much oxide of iron in the slag; it is that of loss. Both in the basic-Bessemer and basic-Siemens processes the oxidation of the iron goes on with such a slag much faster than that of phosphorus. If the phosphorus has to be oxidised easily, and without much loss of iron, the slag must contain an excess of lime. There are thus three advantages in keeping the slag as basic as convenient. The formation of the oxides of iron, and consequently of cold and lively metal, is prevented, the loss of iron is reduced, and a slag with more phosphoric acid, and therefore of more value, is obtained. There is still the difficulty of controlling the carbon in the steel, and so as a partial remedy molten spiegel may be added before the slag comes, but the author prefers to proceed as follows: The steel is teemed as usual (with possibly a previous addition of some ferro-manganese) into a ladle with a large nozzle. From this ladle the soft steel, containing, say, 0·07 per cent. carbon, is teemed into another ladle, until the basic slag begins to come, when the stream is stopped. While teeming the soft steel into the second ladle there is also run into it sufficient alloys to give the required carbon, and at the same time there is run into it some siliceous slag, somewhat similar in character to the ordinary Siemens slag. From this second ladle the steel is teemed into moulds in the usual manner. Thus, by eliminating the tendency to form oxides through the basic slag, it is possible to have the conditions of an ordinary Siemens-Martin charge, and to make hard or soft steel as required.

Mr. Galbraith then proceeded to read his second paper, on "The Estimation of Phosphorus in the Basic-Siemens Steel Bath." One of the difficulties in the basic process is the uncertainty of knowing exactly when the phosphorus is low enough. The usual method is to examine the fracture of a small sample, but this is not entirely trustworthy, as it may vary on account of the size or treatment of the specimen. The following chemical method was accordingly devised. Dissolve 0·20 gramme

of the drillings in 3 c.c. aqua regia in a small flask, then add about 3 c.c. water and sufficient ammonia to precipitate all the iron, and afterwards redissolve the precipitate in nitric acid, adding it drop by drop until the solution is distinctly clear. There is now added about 10 drops of molybdic acid solution, and the solution is transferred to a small bottle, about 2in. high to the shoulder, by ½in. diameter, which after being made up to a definite mark on the bottle, is shaken well. This is also done with a steel containing a known percentage of phosphorus (say 0·05 per cent.), and the opacity is compared; and if a number of similar bottles are kept varying from 0·01 per cent. to 0·10 per cent. phosphorus, the comparison becomes comparatively simple. The method is rapid and trustworthy, and by its means any phosphoric heat can be detected at once. It is not intended to use the test during the blow.

These two papers were discussed together, and the discussion on them was opened by Mr. Paul, who thought that the views offered in the first paper were decidedly new and required consideration. The effect of oxygen on iron has often been dealt with, and he had made experiments to show that brittleness often depended on the presence of oxygen. The author had not, however, given any analyses to show how far oxygen had any effect on the teeming of the metal. With regard to cold heats, when the slag is tranquil the flame passes over it and does not give up so much heat, but he hardly liked to say that Mr. Galbraith's theory was correct.

Sir Lowthian Bell said the effect of the basic slag is to remove the phosphorus when the two are agitated together. Phosphorus is not removed directly by the blast, but only by the oxides in the slag. The agitation of the slag and metal, according to Mr. Stead, causes the evolution of gas by the reaction of carbon and oxides. The addition of silicon spiegel, as used by Mr. Richards, caused the bath to be quieter, and so the iron was not oxidised.

Mr. Allen thought there was some confusion in the paper between the oxide of iron in the slag and in the metal. The method for the determination of phosphorus was a distinct advance; it could hardly be called a colorimetric method.

Mr. Gilchrist said that the slag must contain a large amount of oxides to remove the phosphorus. Darby's process of filtering molten steel through a layer of carbon has been considerably used on the Continent for making the harder grades of steel containing from 0·2 up to 1·0 per cent. of carbon with a low percentage of manganese.

Mr. Edward Riley said that the method of determining phosphorus had already been used on the Continent, but Mr. Stead pointed out that the method there used depended on the measurement of the volume of the precipitate, and not on the turbidity produced.

Mr. Richards defended the sample method of testing. The sample is always of uniform size, and uniformly treated, so that it is possible to estimate phosphorus within a few hundredths per cent. His experience with spiegel was that more was used for the acid than for the basic process. He also referred to the use of silicon spiegel.

Mr. Wailes preferred to dilute the slag at the end of the operation with an excess of lime, instead of using silicon spiegel to prevent the evolution of gas.

Mr. Galbraith then shortly replied to the various objections that had been made. He agreed with Sir Lowthian that phosphorus was removed by the slag, but it was the excess of slag that affected the teeming. With a thin slag it is impossible to get the heat for teeming the metal properly; the furnace would be melted down first. He had had no experience with Darby's process, but he thought that there would be considerable difficulty in obtaining the correct proportion of carbon. He had not been aware that his process for determining phosphorus had already been used in Germany, or he would not have read a paper on that subject.

The last paper was by Mr. Rollet on "The Rollet Process for Producing Purified Castings." This process of purifying pig iron is intended to be auxiliary to the manufacture of special qualities of steel, its object being to eliminate sulphur, phosphorus, and silicon from the castings. It consists in melting pig iron, and maintaining it at a very high temperature under a double action, slightly reducing and slightly oxidising, in the presence of a slag obtained by admixtures of limestone or lime, iron ores, and fluor-spar, in proportions depending on the quality of the pig or castings employed. The apparatus employed for this purpose is a blast furnace or modified cupola, using coke and hot blast. The burdens are introduced in the same way as in blast furnaces and cupolas. It consists of a shaft, several rows of tuyeres, a siphon arrangement for separating metal from slag, and a front chamber.

It has a sheet metal casing and is lined preferably with magnesia. Water jackets are used where necessary. Water tuyeres are used and project into the furnace; the lower row are placed near the hearth so as to prolong

Digitized by Google

the action of the blast on the slag and metal in order to ensure a greater elimination of phosphorus. The metal is separated from the slag as soon as possible, so as to remove the phosphorus and to prevent too great a recarburisation. The temperature of the blast is as high as possible to prevent clogging at the tuyeres. The production is 50 to 75 tons daily; the elimination of sulphur is complete up to 99 per cent., and the phosphorus up to 80 per cent. or even more. A casting may be treated over again, as the carburising action is limited, and so any degree of purity may be obtained. The product may be used in a Siemens acid furnace, or for puddling, crucible melting, or cementation.

Only one speaker made any remarks on this paper. Mr. Hugh Bell said he had been doing the same as Mr. Rollet at the Clarence Iron Works, Middlesbrough, but as yet he had not been led to attach great importance to the method. Practically, all the sulphur is eliminated, and also the larger part of the silicon, but only a small proportion of the phosphorus is removed. He was sanguine, however, that in time the process would be developed, and it was useful to show that more than one mind was working in the same direction.

Lord Granville then proposed a vote of thanks to the President, who, in his reply, referred to the approaching visit to America, and requested the support of all the members. The other usual votes of thanks were also passed, and the meeting terminated.

WATTS' DOUBLE BAND SAW MACHINE.

Timber is generally cut into planks and boards by means of vertically reciprocating saws, but in some cases, when the logs are smaller, by means of circular saws. Both these methods of sawing, however, are rendered expensive in power by the friction which is inherent to the operations, and a great deal of waste is also caused owing to the thickness of the saw kerf. The band saw, in which there is a very small surface in contact with the timber, owing to the comparative thinness of the blades, has not generally come into use for deep cutting; but Messrs. John Watts & Co., of the Broad Weir Engine Works, Bristol, have lately brought out a substantial band saw machine capable of making two cuts 24in. deep simultaneously. We illustrate this machine in Figs. 1, 2, and 3 herewith and on pages 460 and 468. One very distinctive feature in their machine, in addition to that just mentioned, is that the portion of the saw blade actually engaged in cutting does not, as is usual, form a tangent to its carrying pulleys, but is thrust outwards by guide or distending pulleys in a line parallel with the tangent. The blade is thus supported so rigidly, both above and below the timber, that a perfectly straight and uniform cut is produced, and a much thinner blade can be used. The kerf is barely $\frac{1}{16}$th of an inch, and the surfaces, whether in hard or soft woods, are so true and smooth as to require very little subsequent planing. To the underside of the base plate, which is at the floor level, are attached the inverted plummer blocks of the driving shaft, with its fast and loose pulleys, the two saw pulleys, and the cone pulley for driving the feed gear. On each side of the upper portion of the vertical member of the standard are V-slides, in which the pulley arms carrying the bearings of the upper saw pulleys have a vertical range of about 18in., this being sufficient for a wide range of different length saws. For maintaining the saws at the requisite degree of tension for cutting, the pulley arms are slung from the inner ends of the two leaf springs, the outer ends of which are drawn downwards by screws at the back of the machine and within easy reach of the workman. Both saws, shown by dotted lines A A^1 (Fig. 1), are driven by the same shaft and pulley, and therefore at the same speed; and yet each saw may be adjusted independently of the other. A belt from the feed cone pulley on the main shaft below the floor drives the corresponding pulley on a transverse shaft. On this shaft there are worms which gear into four worm-wheels, and these latter are keyed to mitre wheels driving the four feed rollers in the back fence. By means of horizontal shafts which are provided with feather keys, and are free to slide in and out of these mitres when it is required to remove the saws, motion is transmitted to the mitre wheels driving the corresponding four feed rollers, which are mounted on the front fence slide. These rollers are contained in brackets, the bases of which slide in V guides, and are held up against the timber whilst it is being sawn, and are capable of moving inwards and outwards, adjusting themselves to any irregularities there may be on the outer surface of the timber to be sawn. This very necessary adjustment is effected by means of the counter-weighted levers which terminate in sectors working through intermediate wheels into racks on the front fence slide. The saws are set out and supported close to the work both above and below the cut, by means of guide pulleys B B^1 and C C^1, for giving rigidity to that portion of the blade which is actually engaged in cutting, and the leading saw has a lateral movement for determining the thickness of the second board. The upper and lower guide pulleys of the leading saw have their bearings in brackets sliding horizontally in the upper and lower members of the standard. Both brackets are controlled by a screw, a few turns of which will bring the leading saw in advance of the following saw to any required distance within the range of the thickness of the timber to be cut. The usual practice is adopted of supporting the back of the saws against the thrust of the feed by steel rollers.

In several mills, where these double band saw machines are in use, flitches or planks 3in. or 4in. thick are taken from the horizontal reciprocating saw to be re-sawn by the double band saw, thus ensuring a considerable saving in time, as the greatest speed of cut of the horizontal reciprocating saw seldom exceeds, say, for timber 20in. wide, 1ft. per minute, while it gives only one cut, as against two cuts of about 4ft. per minute each for the double band saw. Inch boards up to 24in. wide may be re-sawn with two simultaneous cuts, giving a total net produce of $\frac{3}{8}$in. The double band saw machines will re-saw fine woods 1in. thick by 24in. wide at a speed of feed of about four lineal feet per minute for each saw, thus giving with the two saws a speed of cut far beyond anything that can be obtained from a frame saw while cutting timber of equal width.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 13th May, 1890.

IRON.—The iron market is distinguished by a firmer tone this week; not, however, from any revival of business, but in consequence of the strikes in the coal-mining industry and the fear of similar disturbances among the iron workers. The merchants of the capital refuse to sell bars or joists under 156s. a ton. Old rails are weaker, and are now quoted 88s. The provincial markets are generally quiet, but firm, for the reason given above. If there is any weakness anywhere, it is in the market for pig iron, for which there is but little inquiry. Founders in the Haute Marne are short of work.

THE FOREIGN TRADE.—The Customs returns for the first quarter of the current year show a clearly marked and persistent revival of trade. The declared value of the imports were: For January, 334·6 million francs, an increase of 29·4 millions on January of 1889; for February, 393·4 millions, an increase of 21·2 millions; and for March, 393·7 millions, an increase of 15·2 millions relatively to the corresponding months of last year. It is important to note that the increase in the value of the imports is confined to raw materials. The trade in foreign manufactured goods has diminished. The declared value of the exports in the first three months of the year reached a total of 853·1 million francs, an increase of 60·3 millions on the same quarter of 1889. A notable proportion of this increase is due to expansion in the trade in manufactured goods. These important features—larger imports of the raw materials of manufacture and larger exports of manufactured goods—afford incontestable proof of greater activity in the home industries.

HOURS OF LABOUR.—There are now three Bills before the Chamber of Deputies relative to a reduction of the hours of labour, the industrial question that is monopolising public attention. The first of these, brought in by M. de Mun, is intended to introduce English practice, namely, five working days of ten hours and one of six hours a week, leaving the latter half of Saturday and the whole of Sunday as periods of complete rest. The second, for which M. Piérard is responsible, proposes simply to fix the length of the working day at ten hours. The third, signed by MM. Ferroul, Baudin, and Thivrier, the Socialist Deputies who were at the head of the May Day manifestations, is nothing more nor less than the reproduction of the resolutions voted at the International Socialist Congress last year. These several proposals have been referred to the Labour Commission to report on. This Commission has completed its report on the question of women and children's labour. It is unanimous in prohibiting night work for women. It recommends the limiting of the working day for women to ten or, at most, eleven hours, and the prohibition of all work for children under thirteen, except in cases where they, being twelve years of age, can show a certificate as proof of having reached a certain standard of education.

THE LIGHTING OF PARIS.—At the meeting of the International Society of Electricians at Paris, on the 7th inst., M. Fontaine, the President, read an interesting paper on the "Lighting of Paris." He made a comparison of the amount of light used in the years 1855, 1872, 1877, 1883, and 1889, and gave the approximate figures for each source of light, such as candles, paraffin lamps, gas, compressed oil gas, and electricity. On the whole, paraffin oil is the most used at present, gas remains stationary, and electricity is rapidly growing in favour. The consumption of tallow candles has fallen from 1,200,000 kilogs. in 1855, to 800,000 kilogs. in 1872, 600,000 kilogs. 1877, 400,000 kilogs. in 1883, and 450,000 kilogs. in 1889; whilst the consumption of wax candles during the same years was—50,000 kilogs., 30,000 kilogs., 35,000 kilogs., 45,000 kilogs., and 50,000 kilogs. The calculation of the amount of vegetable oils used for lighting purposes is difficult, on account of these oils being also used in cooking, &c. The employment of mineral oils commenced about 1855, and gradually increased until 1883, since when it has advanced rapidly. The consumption of gas during the same years is given in the following table:—

1885	40,000,000	cubic metres.
1872	144,000,000	,, ,,
1877	150,000,000	,, ,,
1883	253,000,000	,, ,,
1889	289,000,000	,, ,,

Compressed gas has only recently been adopted; 6,500,000 cubic metres were consumed in 1889. Electric lighting commenced in 1877, during which year 230 h.p. was in use; the horse-power in 1883 was 900 h.p., and 1889 17,400 h.p. During 1889 there were 322 installations driven by steam engines, 97 by gas engines, 77 by compressed air, and 22 by vacuum. In addition to the 17,400 h.p. actually in work, there are installations representing 10,500 h.p. in course of construction.

BERLIN, 12th May, 1890.

IRON.—The iron market is steady and the tone somewhat stronger than it was a week ago, the recent reductions in prices having placed the trade on a more practicable basis. The effect of these reductions in the markets of the Western provinces is no longer observable in Upper Silesia, where the demand continues active. Business is especially brisk in joists, which are very firm in price. The state of the trade in crude iron is such as to guarantee the continuance of prosperity for some time to come. The Donnersmarkehütte blast furnace owners have contracted to supply the Finished Iron Makers' Association in the course of the current year with 15,000 tons at 80s. a ton, and 4,500 tons at 84s. a ton. A second contract disposes of the whole of the produce in the next two years, that is, in 1891 and 1892, according to a sliding scale dependent on the price of bar iron. Founders are still very busy, and there is no diminution of activity in the machine shops. The imports of pig iron are still heavy; but fresh business in foreign iron now takes place on only a small scale.

GERMAN IRON ABROAD.—The key to the recent reductions in the price of German iron is to be found in the Customs returns for the first quarter of the year. Foreign iron, finished as well as crude, was being imported in rapidly increasing quantities, while the exports of German iron were as rapidly falling off. The total of the exports in the month of March reached only 68,413 tons, against 79,294 tons in the shorter month of February. The following is a classified account of these exports in the first three months of 1890 and 1889 brought together for the purpose of comparison:—Pig iron, 31,274 (50,876) tons; old and scrap iron, 6,421 (7,265) tons; half-wrought iron and steel, 3,794 (5,836) tons; finished iron and steel (angles, bars, and plates), 49,688 (75,130) tons; iron and steel wire, 29,767 (47,417) tons; wire nails, 8,977 (13,260) tons; rails, 31,421 (25,348) tons; other railway iron, 15,298 (12,490) tons; heavy castings, except ordnance, 5,849 (3,424) tons; other manufactured goods, except machinery, 29,552 (27,118) tons. Total, 212,041 (268,164) tons—a falling off of about 21 per cent. The shrinkage, it will be observed, is in finished iron and steel, wire, and wire nails. The shipments of wire nails to Great Britain in the three months amounted to 3,221 tons.

METALS.—The general aspect of the metal market has changed in the course of the last week. The reduced prices have brought speculators into the market. Brisk buying has taken place, and, as a consequence, prices have recovered a little, and still show an upward tendency. Copper is quoted higher for English brands, and is very firm for Mansfield refined. Tin has improved, Banca being quoted at £5. Spelter has recovered 10s. a ton. Lead has shared in the improvement in a slight degree. This stronger tone of business is likely to bring consumers into the market.

STEERING BY ELECTRICITY.—An officer on board the German ironclad "Preussen" has, in conjunction with the engineer of that ship, invented an electrical steering apparatus, about which there is much talk just now in naval circles. By means of this apparatus the captain can control the rudder from the bridge or from any point on the deck—an important advantage in the noise of a storm or in action. That the invention is regarded by the authorities as one likely to prove of great importance is shown by the fact that the ironclad "König Wilhelm," on the very next day after her return with the Mediterranean Squadron, was sent to sea to test it.

A SHIP CANAL FOR BERLIN.—At a recent meeting of the Berlin Polytechnic Society, the possibility of constructing a canal between Berlin and Stettin was discussed. A canal between Berlin and Stettin offers no extraordinary difficulties, and the cost is estimated at 265,000,000 marks. It would be advisable not to go up the Oder to Schwedt. The shorter way is from the Tegel Lake to Schönwalde; then proceeding in a westerly direction to Bernau and past Biesenthal, and cutting the Finow Canal near Steinfurt. It would be best to lay the locks north of Steinfurt and near Neustadt. The total length of this canal to Stettin would be 160 kilometres. A depth of water of 6½ metres would be available, which is amply sufficient for marine vessels. The estimated traffic on the canal in two hundred and fifty days is 8,000 vessels.

THE ODER-SPREE CANAL.—The opening of the great Oder-Spree Canal which leaves the Oder near Furstenberg, will probably take place in the course of the present month. At first vessels of a carrying capacity of 300 to 350 tons were only expected to be used on this canal, but vessels of 750 tons are now being built, and they will be able to pass Berlin when the Spree bed has been lowered. The canal has a depth of 2½ metres and a breadth of over 50 metres. The canal is the most important hydraulic work at present existing in Germany.

A NEW BUILDING MATERIAL.—A material known as xylolithe has been introduced by Messrs. Cohnfeld & Co., of Pottschappel, Dresden. Xylolithe is composed of a mixture of sawdust and certain chemicals, and is compressed into plates at a pressure of 2,500,000 kilogs. per square metre. Without losing the property of wood, it possesses the hardness of stone, and it is practically fireproof. A 7-centimetre cube of the material was exposed to the action of a coal fire in the heating chamber of a stove for five hours at the Royal Experiment Station without taking fire or the internal structure being destroyed, although it became red hot.

VIENNA, 12th May, 1890.

THE IRON MARKET.—The business in the iron market has been restricted within narrow limits lately, but the tendency is firm, and prices have not changed. It is not possible to say what is the cause of this absence of life. It may be that the uncertainty as regards the actions of the labourers has caused the buyers and sellers to shrink from entering into contracts; but, on the other hand, it may be the influence of the German and English markets and the fall of prices in foreign countries. The works are well supplied with orders, the completion of which will occupy a long time. The 1st of May demonstrations were followed by many strikes in the iron industry, principally in Prague, where five machine works will have to cease work shortly. There is a good prospect for railway construction. In Styria 10,000,000fl. is to be employed for railway purposes soon. After two years of interruption, the Simmering Waggon Building Company is now paying a dividend amounting to 8fl. for each share. The company last year made a profit of 300,000fl., whilst the previous year the loss amounted to 76,000fl.

THE COAL MARKET.—The coal market continues to be animated. The strikes in the Ostrau district have terminated, and the business has regained its old briskness. The union of the Westphalian coke producers has failed to influence our market; indeed, coke prices are very firm, and an increase is to expected. The Lankowitz Coal Company produced last year 54,000 tons of coals, against 46,000 in the previous year; the profit amounted to 32,000fl., and a dividend of 4½ per cent. has been declared. For steamship purposes a great part of the fuel comes from England, and the largest steam-shipping enterprise of Austria, the Austro-Hungarian Lloyd, is using English coals exclusively. The increase of the import of coal from England is visible in the following table:—

	Tons.	Value in Florins.
1885	141,138	 1,933,298
1886	159,503	 2,110,420
1887	164,956	 2,098,202
1888	176,376	 2,317,117
1889	178,249	 2,513,277

BRUSSELS, 13th May, 1890.

THE IRON MARKET.—The state of the iron trade is the reverse of satisfactory. The orders come in very irregularly, and they are hardly worth having when they do come. The prices cannot be quoted with any certainty, as they vary with each order. The prices of the raw materials are so very high, that perilous times are ahead for the iron merchant if affairs do not take a better turn shortly. A good many makers are keeping their works going for four days a week, but they are only increasing their stocks and so placing themselves in a worse condition than ever. There is some talk of an increase in the number of blast furnaces at Thy-le-Chateau and Monceau, a step which appears to be little short of insanity. Steel is in a much better condition at present, although the state of the English market is likely to have an adverse effect upon the markets in Belgium before many weeks are out. There are sufficient orders to occupy the mills for some time, and the prices are remunerative.

THE COAL MARKET.—The prices have not changed very much during the past week. The strikes have had some effect in sustaining them, but the tendency is towards a fall. Indeed many concessions have been obtained—more than was expected a week ago. The condition of the coke makers has not been good during the whole of April, and a large number of furnaces are, therefore, to be damped down in order that the commodity may become more scarce. The price of 35fr., which has ruled in the coke market for a long time, was broken a few weeks ago by the low price of German coke. However, the figure has never gone below 30fr., and most of the business has been transacted lately at 32fr. The exports of coal during the first three months of the present year compare very favourably with those of the corresponding period of 1889. Altogether 344,983 tons were exported, as against 284,822 last year. The imports also increased from 4,727 tons to 7,675 tons. The Government will shortly take over the canal from Bossuyt to Courtrai, and the consequent reduction of the tariffs will be a considerable aid to the export of coal from the Charleroi district.

GLASS.—Very little can be said of the glass market this week. The same depression continues, and the production is too great for the demand. However, several manufacturers have damped down their furnaces, and this course of action will probably be followed by a number of others. Several satisfactory orders have come from England, and the American buyers have renewed their orders, but at reduced prices.

DÜSSELDORF, 13th May, 1890.

IRON.—Business in iron is gradually settling down on a more solid basis now that prices are in better accord with those of foreign markets. The demand, however, shows no signs of immediate revival, but hopes are entertained that some improvement will take place in the course of the next month. Following on the reductions of last week comes the announcement that the West Germany Sheet Makers' Association has reduced the price of sheets 25s. a ton, making the present quotation 225s. The manufacturers of joists have resolved to maintain the present rates, which were formerly low relative to those for bars and plates. Bars are in very slack demand, both for home consumption and for export, and wire is neglected. The state of the export trade in wire causes much anxiety. Relatively to the corresponding period of last year, the exports of wire in the first quarter of the current year have fallen off 37 per cent. The production of pig iron in the Rhenish-West-

Digitized by Google

phalian district in the month of April amounted to 118,756 tons, against 127,231 tons in March. Notwithstanding this diminution, the stocks increased from 40,656 tons to 47,483 tons.

COAL.—The foreign trade in coal continues active in the matter of imports, but the exports compare unfavourably with past years. The statistics of the imports in the first three months of the years 1890 and 1889 are as follows: Lignite, wholly from Austria-Hungary, 1,515,280 (1,054,884) tons; coal, chiefly from Great Britain, 799,820 (735,813) tons; coke, chiefly from Belgium, 120,607 (64,064) tons; and briquettes, from Belgium and Austria-Hungary, 16,998 (6,181) tons. The exports of German produce in the same time consisted of 2,080,752 (2,258,839) tons of coal, 3,236 (2,306) tons of lignite, 210,319 (222,171) tons of coke, and 24,656 (26,046) tons of briquettes.

PRICES OF IRON CASTINGS.—At the general meeting of the Lower Rhenish-Westphalian Association of Ironfounders, held the other day at Dortmund, it was resolved, in view of the increased cost of production which the new labour laws must occasion, to maintain the present prices for castings.

RAILWAY SPEED ON SECONDARY LINES.—The Bundesrath has under consideration a proposal to increase the speed of railway trains on secondary lines from 30 to 40 kilometres (18½ to 24¾ miles) an hour. This measure has been rendered necessary by the great increase of traffic in the last two years.

LILLE, 13th May, 1890.

IRON.—The strikes in the coal-mining industry of the Pas de Calais have given rise to much anxiety on the part of the ironmasters. There is no scarcity of coal yet, but many are nearly at the end of their stores. It is not surprising that in such circumstances manufacturers maintain their prices firmly. There is, however, no revival of business. Consumers buy sparingly and sufficient only for present necessities. The market is supported by the prospect of higher costs of production arising out of the contemplated changes in labour legislation; certainly not by a strong current of business, or even by the hope of brisker trade.

TEXTILE MANUFACTURES.—The state of the market for linen goods has not materially changed in the course of the last week. The amount of business transacted is fairly good, and the prospect has nothing discouraging in it. The woollen goods trade of the Roubaix-Tourcoing district has, of course, been deranged by the great strike of weavers and spinners; but the current of business has not been completely stopped. No one believed that the conflict would last long, and as a matter of fact it has practically ended. A brisk business is being done in raw wool. The commoner qualities of home production are in good demand, and prices have an upward tendency.

FLAX AND YARNS.—There is no abatement of the demand for home-grown flax, but rather an increase; as a consequence, prices are steadily advancing. The supply is scarcely sufficient to satisfy the demand. A similar state of things is reported from the markets of Belgium. Russian produce, too, is being largely dealt in at higher prices. The better classes of tows are in brisk demand. The business done in yarns continues sufficient to absorb the whole of the production, so that the market remains firm. There is an active market for jute yarns.

GLASS WORKS.—The window glass and glass bottle works of Renard & Sons, at Fresnes, have been converted into a share company, with a capital of 2,030,000fr. Henceforward they will be known as the Verreries de Fresnes-sur-Escaut.

AMSTERDAM, 12th May, 1890.

THE PORT OF ROTTERDAM.—The East African Steamship Company, of Hamburg, which is going to start the new line of subsidised mail steamers between that port and East Africa, has decided to make Rotterdam a port of call for their outgoing vessels.—The town authorities have proposed to the Town Council to build a third dock, as the existing accommodation has proved insufficient in consequence of the growth of the town and the rapid development of its trade. The Town Council had already decided to construct such a dock in April last year, for which it had allowed a sum of 700,000 guilders. The new proposal is, however, to build a dock that is estimated to cost 940,000 guilders, with a depth of 6 metres and a length of 110 metres, and to accommodate vessels of 6,000 tons.

POSTAL MATTERS.—The Dutch Government has introduced a Bill into the Second Chamber of the States-General for the amendment of the present Postal Act. The postage of letters is to remain as at present, but the maximum weight of 1,000 grammes per letter will be abolished. As for newspapers, the postage will remain ½ cent. for every copy, which is less than half a farthing, whilst the maximum weight will be raised to 35 grammes for a single postage or part thereof. Up to 100 grammes in weight, a newspaper (including its supplements) may be sent through the Post Office for 1 cent., which rate will be maintained for any weight above 100 grammes. It will become lawful to send newspapers by rail or boat at a special rate.

THE NEW CUSTOMS BILL.—The Commission of the Second Chamber has submitted an unfavourable report on the Government proposal for a revision of the Customs dues upon the basis of an *ad valorem* tariff.

THE FORTHCOMING EXHIBITION AT AMSTERDAM.—The Government has granted a subsidy of 3,000 guilders in aid of the forthcoming Exhibition at Amsterdam of appliances for the minimising of danger to workmen in factories and workshops.

NEW STEAMSHIP LINE.—Efforts are being made for the establishment of a new line of steamers between Holland and Mexico.

COPENHAGEN, 10th May, 1890.

RAILWAYS IN SWEDEN.—The works on the Swedish State Trunk line in the north of Sweden will now be proceeded with in earnest, and the Swedish Parliament has just voted 4,665,000kr. for the next financial year for this purpose. There can be no doubt that this line will really be of very great importance to industry and commerce in Northern Sweden, and the decision of the Parliament has been received with much satisfaction.—The Swedish Government has introduced a Bill authorising the purchases by the State of the Swedish Norwegian Railway. The sum required for the purchase is 7,000,000kr., or about one-fourth of the company's debenture debts; 4,725,000kr. will be required for putting it in good repair and for purchasing rolling stock.

SHIPBUILDING IN NORWAY.—The iron ship "Skonvar" was launched on the 23rd ult. from the Laxevaag Engineering and Shipbuilding Company, Norway. Her principal dimensions are as follow:—Length, 273ft.; length between perpendiculars, 250ft. 6in.; breadth, 38ft.; and depth in hold, 22ft. 6in. The "Skonvar" is the largest sailing vessel hitherto built in Norway. The Laxevaag Company is at present very fully employed. They have in hand a 4,000 tons steamer, a steam ferry boat, and two or three important repairs. The new steamer "Britannia," intended for the Newcastle-Bergen trade, and specially built for tourists, is approaching its completion, and is being fitted in the best possible manner.

MAGNETIC SEPARATORS.—Two magnetic separators have recently been sent to Nepaul from the Anboga Mechanical Works in Sweden. These separators are designed by Mr. J. Wenström, and are similar in size and general aspect to those illustrated in *Industries*, Vol. VI., page 114. The only difference is that the frame is arranged above the apparatus, which is suspended from it in brackets, and that the feeding apparatus is altered to suit the fine materials to be worked. To each separator has been attached a dynamo giving 50 volts and 4 amperes for the magnetisation.

TELEPHONES IN SWEDEN.—The widespread use and development of the telephone in Sweden is something extraordinary, considering the thinly peopled country and its small resources. The telephone may be said to be an important household article, and it may be safe to assert that in no other country in the world do the children and servants in a house use the telephone daily to make appointments, to order supplies, to discuss business, and talk with friends, &c.

MADRID, 12th May, 1890.

NEW IRON ORE DISTRICT.—The first shipload of iron ore from the Carieno mine in Asturias has been exported from the port of Gijon. The cargo was only a little over 400 tons, as the port will not accommodate vessels of large draught. It will be seen that on account of the smallness of the harbour the new mine will never be developed to any great extent.

A CABLE TO CUBA AND PORTO RICO.—The Minister of the Colonies of Spain advertises for tenders, to be received during the ninety days from the 3rd inst., for the laying of an electric cable from Spain to Cuba and Porto Rico. The cable is likely to be the longest that exists, as it will exceed 5,000 miles. The intention of the Government is to leave a good deal to the judgment of the applicants, both technically and commercially, and they will not fix beforehand any special conditions to which the proposals are to be subject. It is clear that some assistance will be required from the Government, for the cable could hardly be self-supporting.

OUTPUT OF LEAD ORES.—The output of lead ores at Linares and Carolina district, from the 1st of January to the 31st of March, 1890. are given in the following table:—

	Tons.
Figueroa & Company, Arrayanes Mine	6,493
Thomas Sopwith, La Fortilla Group	2,260
Andres Pereda, San Miguel Group	1,705
Linares Company, 15 mines	1,653
Fortuna Company, 26 mines	1,471
Mamillos Company, 21 mines	937
Heredia Sons, 3 mines	791
Socorro Company	757
Familia Company, Los Angeles Mine	738

There is every prospect that the output will increase and some new mines are to be started soon. The above-mentioned companies produce two-thirds of the total output, which is 28,000 tons by 68 companies in 306 mines.

THE LABOUR QUESTION.—The labour question caused some anxiety to the authorities during the first week of May. However, all the meetings were quiet enough everywhere, with the exception of Barcelona, Valencia, and Alcoy. The strikes of labourers of some industries are still continued, but generally the employers have acceded to the eight hours demand. In the cotton mills the employers say they cannot allow only eight hours' work unless it becomes general in the competing countries.

A SCHOOL AT THE SHIPBUILDING YARD IN BILBAO.—On the occasion of a recent visit to Bilbao of Sir Charles Palmer, a school was opened which is expressly intended for the children of the British labourers there employed. Sir Charles Palmer and Señor Martinez de las Rivas are much praised for their liberality and goodwill.

NEW YORK, 3rd May, 1890.

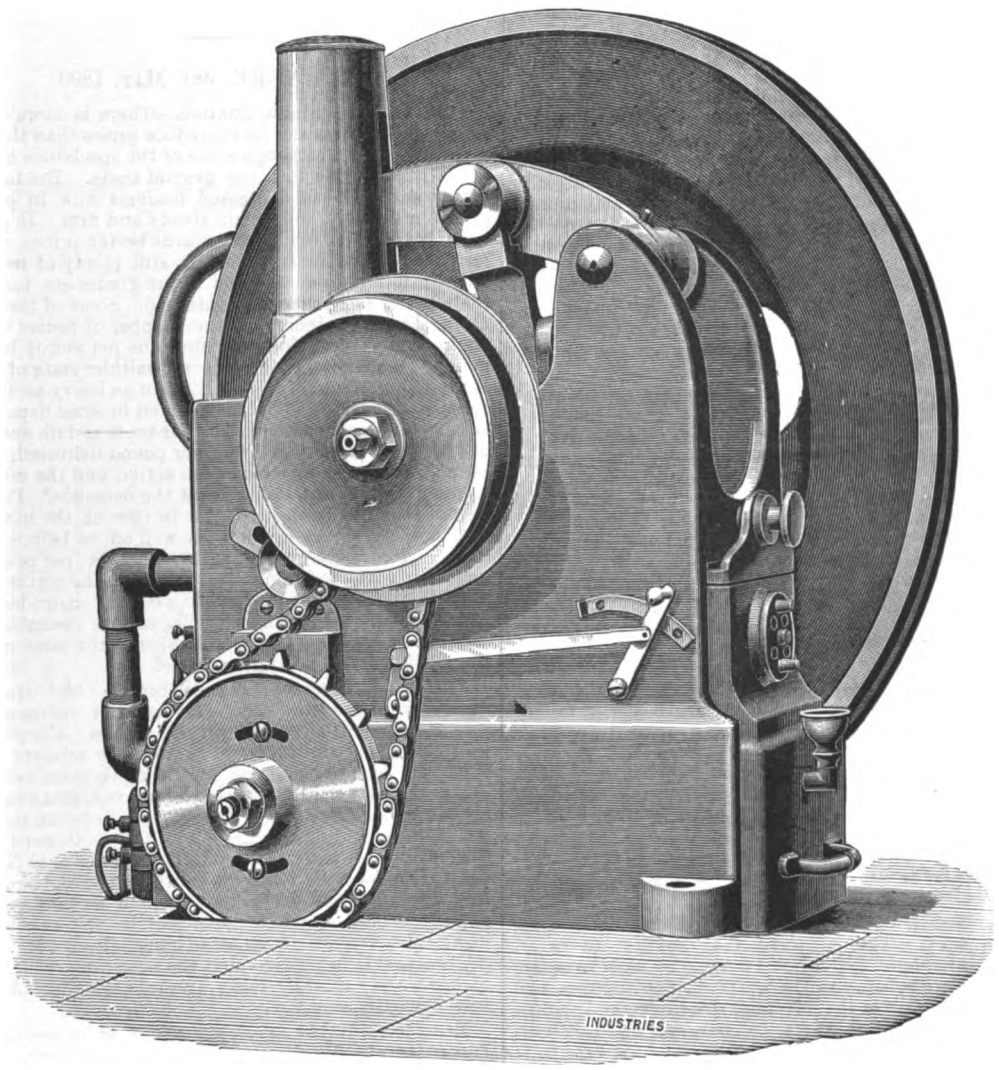
THE IRON AND STEEL TRADES.—There is more disposition to do business and less to reduce prices than there was a short time ago, although some of the specialties have not yet fallen into line with the general trade. The feeling is better, and with the increased business now in prospect prices are likely to remain steady and firm. In pig iron there is a decided tendency towards better prices, particularly in foundry irons. There is still plenty of iron to be had at low figures, but the better grades are bringing a little better rates than a month ago. Some of the owners of furnaces have increased the number of orders on their books, and as other furnaces are to be put out of blast the general tendency is towards a healthier state of affairs. Business in manufactured iron is not as heavy as it ought to be at this season, but the demand in some departments is becoming quite active. The bar trade is dull, and prices are weak, at 1·85c. to 1·90c. per pound delivered, for best refined. Plates and shapes are active, and the mills have as much as they can do to meet the demands. Prices are not what might be desired, and in view of the increase in cost manufacturers are not as well off as before the advance. Plates are quoted at 2·10c. to 2·15c. per pound, and angles at 2·20c. to 2·25c. In steel rails the market is dull and prices are rather inclined to weaken. Sales have been made at $33 by Pittsburgh mills, and on desirable orders Eastern mills would probably accept the same rates, although $34 is the usual price asked.

THE COAL TRADE.—The anthracite coal trade has decidedly improved. The demand has increased, and prices are from 10c. to 20c. per ton higher. The producers have the market in their own hands. An attempt will be made at the next meeting of the representatives of the great companies to raise the prices, and this course will probably be carried out. The outlook is favourable for a much heavier trade from now. The settlement of the difficulty about the rates for bituminous coal to Northern points has been quite an important event to all the carrying companies, for the contest for coal to Buffalo and other points has been very damaging. Under the new arrangement rates for coal will be advanced from 74c. to $1·10 per ton, and it is believed that the new rates will be fully maintained by all the roads. The tonnage affected is more than 4,000,000 annually.

MOUNTAIN RAILWAYS.—The peaks of Ixtaccihuatl and Popocatapetl in Mexico are to be made accessible to tourists, and a concession has been granted for a railway to connect them with the Inter-Oceanic Railway. As the latter mountain is 17,800ft. above sea level, or about 10,000ft. above the Mexican tableland, there will be some heavy engineering work in building the road.

DESTRUCTION OF SINGER'S SEWING MACHINE FACTORY.—The works of the Singer Sewing Machine Manufacturing Company at Elizabethport, on Newark Bay, New Jersey, have been destroyed by fire. Three thousand persons have in consequence been thrown out of employment, and a loss incurred of over $2,000,000.

PHILADELPHIA, 2nd May, 1890.



NEW LOCOMOTIVES.—At the Pennsylvania Railroad engineers' offices, at Altoona, a new compound locomotive is being planned, with the object of saving fuel. If the new engine proves a success it will probably make a change in the whole motive power of the road. A new freight locomotive is also being designed, half as heavy again as the largest of any freight locomotive in use at present.

A LARGE GOODS STATION.—The Pennsylvanian Railroad Company, following its policy of making more freight yards between Pittsburgh and Philadelphia, will very much enlarge the facilities at Altoona. The new yards, when completed, will be the largest in the country, and will be nearly three miles long. It will require the digging and hauling away of nearly 800,000 cubic yards of earth, and this work is being vigorously pushed. The Railway Company has large yards at Pittsburgh, Walls, Altoona, Harrisburg, Philadelphia, and Jersey City. Goods consigned to all points on the road come to these yards, and before a train is made up the cars have to be classified. When there is room enough it can be quickly done. Now it is almost impossible to marshal a train in the yards. The Altoona yards will have at first 50 tracks, and room for more when needed.

COKE AS A LOCOMOTIVE FUEL.—Coke is still being experimented with on the Baltimore and Ohio Railway with good results. Six engines on the Philadelphia division and two on the main line now burn coke exclusively. Coke is as clean a fuel as hard coal, and it is claimed to cost very much less. The kind of coke which has been found to answer best is that which has been burned for thirty-six hours.

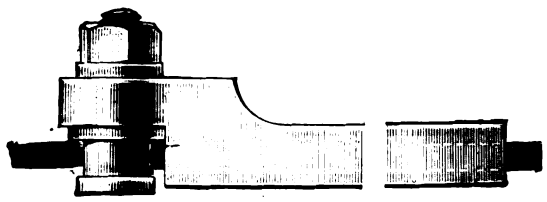
BUTLER'S DOMESTIC PETROLEUM ENGINE.

GUNBOATS FOR THE ZAMBESI.

THE present policy of our Admiralty authorities in the more extended employment of private firms for doing Government work is not only a sound one on economic grounds, but is also a useful and convenient one from a national point of view. The convenience of the policy is well illustrated in two gunboats of the stern-wheel type, named the "Mosquito" and the "Herald," which Messrs. Yarrow & Co., the well-known torpedo boat builders of Poplar, have just completed to an Admiralty order.



The order for these gunboats was given on the 1st April, and the first boat, the "Mosquito," was completed and set to work on the Thames on the 3rd inst., which, after allowing for the Easter holidays and Sundays, leaves twenty-five working days for building. This performance shows what can be done in this country by private enterprise in case of emergency. The dimensions of these steamers are 77ft. in length by 18ft. beam. They have a draught of 18in. with steam up, and run ten statute miles an hour, which is as high a speed as is at all practicable when navigating a very shallow river, the channel of which is not known, and where there are no pilots. The boiler, which is placed forward, is of the locomotive type, and is adapted for burning wood, which is the only fuel obtainable up the rivers in East Africa. The weight of this boiler at the bow is balanced by the wheel and horizontal engines aft, which are of very simple construction. On the main deck are cabins and sleeping accommodation for the chief officer, three petty officers, and eight men, who will form the European crew, in addition to which hammocks will be swung from the upper deck for the accommodation of natives. On the top of the upper deck is placed the pilot tower, from which the steersman can obtain an all-round view.

In arranging for these special service craft the question arose as to the most suitable class to adopt. The difficulties which presented themselves were considerable because it was not possible to ship entire gunboats of sufficient size to be of any practical utility; and it was also out of the question to navigate to East Africa vessels of a description suitable for river navigation, which must necessarily be very lightly constructed and flat-bottomed, and, consequently, too weak to withstand the strains which would come upon them during a sea voyage. It was, therefore, decided to build the boats in sections, and send them out in that form. The usual plan of constructing river boats is to erect them at the builders' yard in the first instance, then take them to pieces for shipment, and ultimately rivet them up and launch them close to the place where they will be used. This plan, however, was deemed undesirable in the present instance, because the river banks are Portuguese territory, and consequently, under existing political conditions, would not be available. Messrs. Yarrow & Co., therefore, proposed to the Admiralty the adoption of the present plan, which they have successfully carried out on one or two previous occasions, viz., to build the hull in floatable sections, each section being really a pontoon or tank, and of such a size as to render it easy of shipment in a ship's hold. On arriving at the destination each section will be lowered into the water, and then connected together by means of suitable straps and bolts, thus making the hull complete, after which the machinery and woodwork will be put on board. It will be readily understood that as each section contains a number of bolt-holes, some provision is necessary to insure floatability when the section is lowered into the water to be connected to the adjoining ones. The provision made by Messrs. Yarrow to meet this difficulty is both simple and effective. The mode of construction not only enables the vessels to be put together quite independent of the river banks on either side, but lends itself to being very speedily carried out. So rapidly can this be done, that Messrs. Yarrow & Co. have undertaken to have the vessels under steam within twenty-four working hours from the time when the sections are lowered into the river. It was felt to be important that the type of craft adopted should be of such a character that all the working parts should be repairable from above the water. In a stern-wheel boat the chief part liable to damage is the wheel, which can be easily got at for repair, in case of accident, while afloat. In comparing this class with a side-wheel boat, the stern-wheeler offers several other advantages. In the first place, the wheel, being at the stern, is well-protected from floating obstructions by the hull, and, in the next place, from a structural point of view, it is possible to build a much lighter craft, and, consequently, of less draught of water, than if the machinery were all placed amidships, as the system of trussing which may be adopted virtually increases the structural depth of the boat. Again, the extreme width of the boat is simply equal to the beam of the hull, while in a side-wheeler the width of the channel necessary for it to pass is equal to the beam of the hull plus the width over both wheels. Each of these boats will carry four 3lb. Hotchkiss quick-firing guns on the main deck, and on the upper deck will be placed a number of ·45in. five-barrelled Nordenfelt machine guns. The engines are not protected, but are scarcely likely to suffer injury in the intended service, as they are of the simple horizontal non-condensing description, with cylinders 10½in. diameter and a stroke of 2ft. 6in. The maximum boiler pressure will be 140lb. per square inch. Messrs. Yarrow built three similar gunboats for the Portuguese Government before the difficulty with Portugal arising out of the over-zealous action of Major Pinto, and they have six more under construction for the same Government. We hope to give an illustration of the "Mosquito" in an early issue.

On Saturday last an opportunity was afforded us for witnessing a trial trip of the "Mosquito" on the Thames, and, having regard to the remarkably quick time in which the vessel was built, the trip was highly successful, and the work reflects great credit on Messrs. Yarrow's enterprise and skill.

BENT'S TOOL HOLDER.

THIS tool holder is intended for use in boring and cutting internal threads. The cutters or tools can be made of ordinary round rod steel, and it is not requisite

to employ a skilled smith in forging them. This holder, which we illustrate herewith, has been designed by Mr. B. H. Bent, Demonstrator of Applied Mechanics at the University of Cambridge, and it is made by the Britannia Company, Colchester.

BUTLER'S DOMESTIC PETROLEUM ENGINE.

THERE should be a great field for a small and simple motor which could be used for household purposes, and many attempts have been made from time to time to produce such a motor. One of the latest machines of this kind is the motor invented by Mr. Edward Butler, of Greenwich, and we have seen one of this pattern at work at Messrs. F. B. Shuttleworth's, at Erith. From the illustration which we give herewith, it will be seen that the motor is very compact and is entirely self-contained. It stands on a base 12in. long by 7in. broad, and measures 16in. to the top of the fly-wheel; these dimensions are smaller than those of any other gas engine in the market. It runs at 1,200 revolutions per minute without load, and at from 250 to 800 revolutions when doing work. The power developed is one-fifth of a horse-power. The explosive mixture is formed of the vapour of benzolene, together with a certain proportion of air. The cylinder is vertical and single acting, and is 2in. diameter by 3½in. stroke. The piston is of the trunk type, with one end of the connecting rod attached to it. The upper end of the connecting rod works a vibrating lever, which transmits motion by a second connecting rod to the crank shaft. The fly-wheel is at the back end of the crank shaft, and the driving wheel is at the front end. The fixed centres of the vibrating lever are on the same casting as the bed-plate. The lower part of the bed-plate forms a small reservoir for the benzolene, and this small receptacle is connected with the main reservoir, which is placed in any convenient position, by a pipe about ⅛in. in diameter. In the present case about a quart is the capacity of the larger reservoir. From the small reservoir the benzolene is drawn up by a pipe about $\frac{1}{16}$in. diameter, and the air, which is passed through a small inspirator, mixes with it and converts it into an explosive mixture. The explosions take place at the bottom of the cylinder once in every two revolutions. The supply of vapour is controlled by a rotating plug

Digitized by Google

valve with suitable inlets and outlets; this valve runs at one-fourth the speed of the crank shaft, to which it is geared by an Evart's chain. Igniting sparks are obtained by a current from a bichromate battery with carbon and zinc elements, and the current is transformed by an induction coil into one of higher pressure. Contact is made twice in every revolution of the valve, and as the valve only rotates at one-fourth of the speed of the crank shaft, this is equivalent to one explosion in every two strokes of the piston. A small water tank placed at a higher level provides the means for keeping the cylinder cool by circulating water around it. A tiny throttle valve regulates the speed of the motor. An opening of $\frac{1}{400}$in. in the valve is quite sufficient for the working of the motor, one-eighth of a turn on a screw with fifty threads to the inch giving this opening. It is stated that the amount of benzolene used is from one-quarter to three-quarters of a pint per hour, so that the cost would not exceed, in any case, a penny per hour.

We are informed that one of these motors has been working for the last ten months at intervals with perfect success. The motor can be fixed on a kitchen table, shop counter, bench, or floor, and the small water tank on a shelf or bracket, whilst the battery, as in the case of house bells, may be conveniently placed in a cupboard or cellar. The motor is started by giving it a few turns by hand, after which it runs without further trouble. The same principle has been applied by Mr. Butler to a three-cylinder compound engine for driving a launch 40ft. long with 6ft. beam, about which we may have more to say on another occasion. The motor appeared to us to do its work very well and without vibration. A syndicate has been formed for introducing these small motors into the market, and is known as the Butler's Petrol-Cycle Syndicate, at 10, Throgmorton Avenue, London, E.C.

SHIPBUILDING NOTES.

On the 22nd ult. Messrs. R. & H. Green launched at Blackwall the first of two composite lightships, which they are constructing for the Hon. Corporation of Trinity House. These vessels are built from designs prepared by Mr. F. C. Goodall, surveyor of shipping to the Trinity House, and their construction presents some novel features. Each is on the composite principle, and is metal-fastened throughout. All the ironwork is coated with soapstone paint, a composition which is now largely employed in iron and steel ships for preventing oxidation, and the bottom has been covered with bitumastic cement, which is lighter and more elastic than any other cement in use for marine purposes. In each lightship there is a large windlass of great power, driven by compressed air, which is supplied and stored by a caloric engine placed in the hold. The first of the two is intended for service at North Haisboro'.

On the 3rd inst. Messrs. Edward Withy & Co. launched from their yard at Hartlepool a large steel screw steamer, called the "Norna," built to the order of Messrs. Herskind & Woods, of West Hartlepool. She is an excellent type of a modern cargo boat, measuring over 300ft. in length, and built throughout of Siemens-Martin steel. The vessel has a long raised quarter-deck, short poop, long bridge-house, and topgallant forecastle. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of steel and iron. In the main and after holds the vessel is built on the web-frame system. The cellular bottom is fitted all fore and aft for water ballast. She will be fitted with triple-expansion engines by Messrs. W. Gray & Co., Limited, Central Marine Engine Works, West Hartlepool.

On the 5th inst. there was launched from Messrs. Craig, Taylor, & Co.'s Thornaby Shipbuilding Yard, Stockton-on-Tees, an awning-decked vessel, built to the order of Messrs. Pile & Co., London, for the Japan Mail Steamship Company. The vessel is of the following dimensions:—Length, 177ft.; breadth, 26ft. 6in.; and depth, 20ft. 6in. Triple-expansion engines are being supplied by Messrs. Hanna, Donald, & Wilson, of Paisley. The cylinders are 13in., 21in., and 34in. in diameter, by 24in. stroke.

On the 5th inst. the steamship "Reaumur" was launched from the yard of Messrs. W. Doxford & Sons, at Pallion. She has been built to the order of Messrs. A. D'Orbigny & Faustin Fils, of La Rochelle, France. Her principal dimensions are:—Length between perpendiculars, 250ft.; breadth, extreme, 35ft.; depth, moulded, 18ft. 6in. The engines are of the triple-expansion type, and have been built by Messrs. Doxfords. The cylinders are 21in., 33in., and 54in. diameter, by 36in. stroke.

On the 6th inst. Messrs. Laird Brothers launched from their yard at Birkenhead the second of the two torpedo gunboats they are building for the Government of the Argentine Confederation. The "Rosales" is a duplicate of the "Espora," launched by Messrs. Laird on the 22nd ult. Her tonnage is 615 tons, and her machinery is intended to develop 3,250 i.h.p.

On the 6th inst. Messrs. Fleming & Ferguson, shipbuilders and engineers, Paisley, launched a paddle tug steamer, "Mana," built to the order of Timaru Harbour Board, New Zealand. The "Mana" is to be fitted by the builders with two sets of independent compound surface condensing engines to indicate 600 horse-power.

On the 7th inst. Messrs. Richard & Henry Green launched from their shipbuilding yard at Blackwall the first of two paddle passenger steamers which they are building for the Bosphorus Steam Navigation Company. The dimensions are:—Length, 165ft.; breadth, 21ft.; and depth, 10ft. She is built entirely of steel, and will be fitted with compound oscillating paddle engines by Messrs. John Penn & Sons, Ld., Greenwich.

Notices of Meetings.

NEXT WEEK.

The Institution of Civil Engineers. — Tuesday, May 20th, at 8 p.m. Paper to be read: "The Keswick Water-Power Electric Light Station," by Messrs. Fawcus and Cowan.

The Society of Arts.—Wednesday, May 21st, at 8 p.m. Paper to be read: "The Mannesmann Process for Making Seamless Tubes," by Mr. J. G. Gordon.

The Royal Statistical Society.— Tuesday, May 20th, at 7.45 p.m. Paper to be read: "The Position and Prospects of Industrial Conciliation," by Mr. L. L Price, M.A.

The Royal Meteorological Society.—Wednesday, May 21st, at 7 p.m. Papers to be read: "Rainfall of the Globe—Comparative, Chronological," by Mr. W. B. Tripp; "Mutual Influence of Two Pressure Plates upon each other, and Comparison of the Pressures upon Small and Large Plates," by Mr. W. H. Dines; "On the Variations of Pressure caused by the Wind Blowing across the Mouth of a Tube," by Mr. W. H. Dines.

PRICES CURRENT, 14th May, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.		Best. £ s. d.	
Middlesbro' Bars	6 5 0	.....	6 15 0	f.o.t. wks.
„ Angles	6 2 6	.....	6 12 6	„

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: A strong market has ruled in copper during the week, and prices have advanced considerably. The old French stocks are still held off the market for higher rates, and this has no doubt been the principal factor in the rise. For some time there has been a scarcity of G.M.B.'s offering for early delivery, and this, aided by a reported improved demand for consumption, has induced speculative inquiry and forced up prices. Throughout the week there has been a very active demand for raw, and a large business has been carried through. Manufactured is now quoted £66 sheets, £69 bottoms.

Tin: A decided advance has taken place in the price of tin during the present week, but an easier feeling is again observable, with a tendency to lower values.

Lead has been dull and inactive, and prices are slightly lower on the week.

Spelter has advanced considerably, the stocks being very small and the output of the spelter works being sold for some months ahead. The galvanising trade continues very slack, but there has been a large demand from India for yellow metal, which absorbs a good deal of spelter. It seems likely that spelter will be dear for some time to come, as the production is regulated by a strong syndicate.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: There have been no changes of moment in the chemical markets during the last week. Bleaching powder has had a fair demand and is steady. Caustic soda is pressed for sale at lower figures. There is less inquiry for soda ash, and prices are rather easier. Soda crystals firm. There is a very strong demand for sulphate of copper, and only small supplies now obtainable for this month. Prices of carbolic acids are unchanged, but there is more inquiry for crystal, and some good sales of crude have recently taken place. Benzoles are firmer. Acetates of lead, lime, and soda are all steady.

HOME INDUSTRIES.

LONDON, 15TH MAY, 1890.

THE MONEY MARKET.—Money has been rather easier this week owing to the freeing of resources by the maturing of Treasury Bills, only part of which were renewed. There has been a good demand in connection with the conclusion of the Stock Exchange settlement, and rates are higher. Discounts have not been quite so firm as last week, the foreign exchanges moving a little in our direction. Something of a lull has occurred in the activity of the stock markets, and a more irregular tendency has shown itself. Home railways have kept pretty good. Brighton Deferred is still weak, but South-Eastern and Chatham stocks have improved. The heavy railway securities have been firm. Caledonians have fallen, and North British risen, on the rejection of the former's and the acceptance of the latter's Bill for amalgamation with the Glasgow and South Western Railway. American railway stocks are still supported, but not quite so energetically as they were for a time. Canadian railways are in favour. The foreign market is strong in tone. Egyptian and Turkish securities have been favoured, and most "international" stocks have advanced a little. South American stocks have had fewer friends. Among mines, copper shares have been actively dealt in at rapidly improving quotations on the rise in the price of the metal. Gold shares have attracted little notice. Nitrate securities have fluctuated considerably. Among industrial companies the market has paid attention to little else but the shares of the two American meat importing companies, Eastman's and Hammond's, which have risen considerably.

COMPANIES.—The following companies have been registered since our last report:—Wilkes, Ld., with a capital of £20,000, to carry on the business of engineers; Collins Automatic Coupling and Continuous Brake Syndicate, Ld., with a capital of £2,000; Gamgee Steam Generators, Ld., with a capital of £100,000; Torbay Brewery and Cider Co., Ld., with a capital of £70,000; Rust's Mosaic, Ld., with a capital of £10,120, to acquire a patent and business for the manufacture of vitreous mosaic; The Kimberley Diamond Mining Co., Ld., with a capital of £100,000; The Lake Superior Queen Silver, Ld., with a capital of £175,000, to acquire certain mining property on the north shore of Lake Superior; D. Davis & Sons, Ld., with a capital of £450,000, to acquire and work certain collieries in South Wales; The Colombian Quartz Mining Co., Ld., with a capital of £200,000; The Thornebury Miners' Safety Lamp Co., Ld., with a capital of £50,000, to acquire certain patents, &c.; The Guanta Railways, Harbour, and Coal Trust Co., Ld., with a capital of £250,000, to acquire the right of constructing certain harbours, &c., and to work certain mines, &c.; Ketley Brick Co., Ld, with a capital of £10,000.

THE BOARD OF TRADE RETURNS.—The exports for April show an increase, and the imports a decrease. The total value of the former was £20,344,367, as compared with £19,634,715 in April, 1889, being an increase of £709,652. Yarns and textile fabrics were £8,270,501, as against £8,547,754, a decrease of £277,253; metals and articles manufactured therefrom, except machinery, £3,785,367, as against £3,272,716, an increase of £512,651; machinery and millwork, £1,269,541, as against £1,201,648, an increase of £67,893; and chemicals, £750,574, as against £632,737, an increase of £117,837. The imports amounted to £35,680,242, as compared with £37,255,785 in April, 1889, being a decrease of £1,575,543. Metals were £1,856,217, as against £1,871,161, a decrease of £14,944; chemicals, dyestuffs, and tanning substances, £786,767, as against £879,505, a decrease of £92,738; oils, £435,581, as against £452,004, a decrease of £16,423; and raw materials for textile manufactures, £9,507,074, as against £9,384,656, an increase of £122,418. For the four months ending 30th April, the exports in 1890 amounted to £83,082,369, as compared with £80,291,594 in 1889, an increase of £2,790,775. In the same period the imports amounted to £140,839,258, as compared with £143,881,786, a decrease of £3,042,528.

CONTINENTAL TRAIN SERVICES.—Some improvements in these services are announced by the London, Chatham, and Dover Railway Company as coming into force on and from the 1st prox. The St. Gothard and Italian Adriatic Railway Companies deserve the credit for these changes. A new express train, first and second class, will leave Milan at 6 p.m., after the arrival of the 11 a.m. from Victoria of the previous day, and will reach Bologna at 9.41 p.m., Florence shortly after midnight, and Rome at 7.35 a.m. This is an improvement of six hours to Rome. On the return journey the fastest express will leave Rome at 8.25 a.m. and Florence 2.37 p.m., arriving at Milan in time to join a new sleeping-car express at 10.20 p.m. for Bâle. Bâle is reached at 8 a.m., and the train starts at 9 a.m. for Rheims, due 7 p.m., Calais due 1.20 night, and Victoria 5.55 a.m. This is an acceleration from Rome to London of ten hours. The sleeping cars from Milan to Bâle will shortly be of a new type, built, worked, and owned by the St. Gothard Company, who have sent men over to England to study the most improved form of east and west coast cars. As a new fast service will leave Rheims at 9 a.m. for Victoria (due 7.25 p.m.), passengers who dislike crossing the Channel at night can conveniently stop at Rheims. The best express from Brindisi to London is also quickened by two hours, but it leaves at the early hour of 5.58 a.m. instead of 5 p.m. The connection from Venice will leave at 4 p.m., reaching Milan 9.30 p.m., improving the service to London by seven hours. It is in contemplation to run a train from Calais to Bâle, leaving Victoria 3.15 p.m., due at Bâle 8 a.m., Lucerne 10.30 a.m., Milan 7.30 p.m. The return is to be from Bâle at 7 a.m., reaching Victoria 11.15 p.m., travelling from Switzerland to London within the day.

THE RATING OF MACHINERY.—In the Rating of Machinery Bill, of the present session, it is proposed to exclude waterworks and gasworks. It would appear that central stations for the supply of electricity to the public are entitled to be placed upon the same footing as gasworks, and an endeavour is being made to introduce an amendment to this effect.

THE JUNIOR ENGINEERING SOCIETY.—At a meeting of this Society, held on the 9th inst., a paper was read by Mr. W. J. Tennant, Chairman, on the "Slide Valve and Radial Valve Gears." The author introduced the subject by a consideration of the elementary principles underlying the action of the slide valve, and then proceeded to a deduction of the proportions and setting of slide valves and eccentrics. The effect upon steam distribution of external and internal laps and leads, and of variations in the setting of the eccentric and proportioning of the ports, was illustrated by a special model, the invention of the author. The Trick, Thom, Brock-differential, double-ported marine, and other types of flat and piston valves were next referred to; and general considerations having reference to reversing and expansion valve gears were followed by an explanation of a graphical method of determining the speed of a valve or piston at every position in its travel. A demonstration, with the aid of models, diagrams, and lantern slides, of the principle and mode of operation of the Hackworth, Marshall, Joy, and Morton radial valve gears, brought the paper to a close.

THE INSTITUTION OF MECHANICAL ENGINEERS.—The summer meeting of this Institution will be held at Sheffield on the 29th, 30th, and 31st of July and the 1st of August next. The Mayor of the town and the Master Cutler are at the head of the reception committee, and the honorary local secretaries are Professor W. Ripper and Mr. R. H. Radford. In addition to the reading of papers there will be a number of excursions to places of interest, technical and otherwise.

THE ROYAL AGRICULTURAL SOCIETY.—The annual exhibition of the Royal Agricultural Society will be held at Plymouth on the 23rd, 24th, 25th, 26th, and 27th of June.

ADELAIDE ROYAL AGRICULTURAL SOCIETY.—Messrs. Ransomes, Sims, & Jefferies, Ld., of the Orwell Works, Ipswich, have been awarded the first prize for their portable steam engines, exhibited at this year's show of the above Society. The report mentions, in addition, that the engine to which the award was made was very much admired for its construction and smoothness of working.

CASTOR OIL.—Messrs. Petty & Co., Silvertown, have recently commenced to work a new process, by means of which castor oil is made palatable. We have tried a sample of it, and find it not at all unpleasant to take.

BUSINESS ANNOUNCEMENT.—Mr. J. D. F. Andrews has taken into partnership Mr. H. Gray, late assistant civil engineer to Messrs. W. H. Barlow & Son, Westminster. The business hitherto carried on by Mr. Andrews as electrical engineer, manufacturer, and contractor will be continued under the style of J. D. F. Andrews & Co., at the same address, 41 and 42, Parliament Street, Westminster.

MANCHESTER, 15TH MAY, 1890.

THE IRON TRADE.—The market for iron shows no signs of improvement. Buyers are not numerous, although plenty of iron is being used. Contracts have not run out yet, but new specifications are not easily obtained. The continued low price of warrants prevents much business being done. Bar iron makers are beginning to be without orders in some cases, and prices are being cut. There are not, however, any large parcels offering, and merchants are able to meet the requirements of the market.

LINEN AND JUTE TRADES.—During the week under notice a fair amount of business has been passing in the fancy departments, and heavy goods have also moved off freely. The principal topic of discussion in that section of our shipping trade more directly concerned with the New World is still the McKinley Tariff Bill, which will, if passed, considerably alter the course of trade from this country to the States. As far as the main clauses of the measure are concerned, it is generally considered that the duties proposed by the framers of the measure are ridiculous, seeing that most of the articles taxed are not produced in the States owing to climatic and other difficulties. In the home trade there is a fair amount of business passing, and sales, considering the season, have been of fair volume. Jute goods are inflated in price owing to the upward movement in raw material. The jute market is always a difficult one to follow owing to the erratic movements of the fibre. Linen threads are in active request at unchanged prices. Manufacturers are well engaged for a long time ahead.

RING BOBBINS.—Messrs. Wilson Bros., Limited, have introduced a method of enamelling ring bobbins, by which they are rendered impervious to damp or oil. It is often necessary to store away bobbins when full of yarn in a damp cellar in order to "condition" the yarn, and sometimes they are steamed. This warps the bobbins as usually made, and renders them untrue. Messrs. Wilson Bros. have taken up an American invention by which an enamel is put on the bobbin. We have made a number of experiments with sample bobbins coated in this way, and find that they resist the action of warm water and oil perfectly. One important feature in the enamel is that it does not become sticky, and the yarn can therefore be easily unwound. Old bobbins, if they are undamaged, can be coated with the enamel, and are then practically as good as new ones.

INLAND NAVIGATION.—An international conference on this subject is to be held in Manchester on the 28th of July. At the meetings papers will be read on various topics connected with canals, and there will be two sections, one of which will deal with the engineering side, and the other with the economic side of the problems involved. An executive committee has been formed, with Sir Joseph Lee as chairman, and Mr. A. A. Gillies, of 46, Brown Street, Manchester, as secretary. A large number of representatives from all over the world are expected to be present at the meeting.

WEAVING PRICES.—One of the chief difficulties existing in Lancashire is caused by the various wages lists existing in different districts. Each district has a distinct list of prices by which wages are regulated, and there is a good deal of confusion in consequence. A determined effort is being made to establish a uniform standard, and the negotiations have now made considerable progress, and a basis for agreement has been established. It is hoped that the adoption of a list of this character will prevent the occurrence of local strikes throughout Lancashire.

GLASGOW, 15TH MAY, 1890.

PIG IRON.—Since our last report the Scotch pig iron market has remained pretty steady, although Cleveland warrants have experienced rather a severe fall. Large transactions have taken place daily within a few pence of 44s. 6d. cash. Warrants seem to be well held, and are, in fact, scarce. It is difficult to reconcile the frequent statements about a falling off in the demand with the good shipments and with the constant large deliveries from the store.

GLASGOW CENTRAL UNDERGROUND RAILWAY.—It is reported, though not yet authoritatively, that the contracts for the central railway to be constructed by the Caledonian Railway will be let as follows:—The eastern portion to Messrs. Charles Brand & Son, the central portion to Messrs. James Young & Son, and the western portion to Mr. A. H. Boyle. The work of constructing the intercepting sewer is proceeding rapidly. This sewer ultimately will form part of the future system of sewage which some day or other the city must adopt. It has been designed with this in view.

EDINBURGH RAILWAY STATIONS.—A proposal has been mooted, which seems to have received some support, to enable the Caledonian Railway Company to acquire the Waverley Market, a huge enclosure below the level of Prince's Street, and situated between that street and the Waverley Station. The project includes the formation of a central station, into which both Caledonian and North British trains should run. The advantage to the travelling public of such a station in the centre of Edinburgh would be very considerable. The Waverley Market belongs to the city, and has for many years been used for great public functions. Normally it is not nearly utilised to the full extent of its space.—The Caledonian Underground Railway Bill has not yet been reached in the press of Scotch business now before the Parliamentary Committees. It will not now come before Sir John Dorington's Committee until after the Whitsuntide recess.

GOLD SHARES.—The shares of the Cassel Company have again been the subject of excited speculation. About three years ago they were to be had for nothing, or even with a gratuity of 6d. per share, subject to contingent liability for calls. When, however, the existing management got fairly to work, the shares gradually advanced. For some time they ranged from 30s. to 35s., but in the beginning of this week they took a sudden jump to 57s. 6d. Subsequently they fell off a little, but the excitement still continues in a more moderate degree. The company has not yet paid a dividend, but great hopes are entertained of the Macarthur-Forrest process of gold extraction which the company now work, the original Cassel process having been long ago abandoned. The cause of the advance in the price of the shares is the receipt of information from the representative of the company, who is now in Colorado, that a company had been formed there for working the process in the United States, and that the sum of $2,000,000 in shares had been allotted to the parent company as the price of the concession. Mr. Macarthur, the technical manager of the company, is in South Africa, and should similarly satisfactory information be received from him the shares may be expected to take another leap upwards.

THE SCOTTISH RAILWAY AMALGAMATION.—After an inquiry of great length, the Select Committee of the House of Commons, presided over by Sir John Dorington, have decided to throw out the Bill promoted by the Caledonian Railway Company for powers to take over the Glasgow and South-Western Railway, with the option to the North British Railway Company to become joint owners. The Committee, however, passed the preamble of the North British Railway Bill giving them powers to acquire, upon agreed terms, the undertaking of the Glasgow and South-Western Railway. In giving their decision the Committee enumerated numerous conditions upon which they passed the preamble, the main objects of which are to grant running powers to the Caledonian and North-Western

Digitized by Google

Railway Companies, and for protecting the interests of traders. The Committee decided to adjourn until Tuesday next in order to allow time for the North British Railway to consider the conditions and to draft clauses.

(From our own Correspondents.)

LIVERPOOL, 14th May, 1890.

Conference of Average Adjusters.—At the conference of average adjusters, held in Liverpool last Friday, some important resolutions were passed which will affect future claims, amongst them being the following:—"That on all claims on ships' machinery for repairs no claims for a new propeller or new shaft shall be admitted into an adjustment unless one adjuster shall obtain and insert in his statement evidence showing what has become of the old propeller or shaft;" "That the managing committee consider the question of the revision of the York-Antwerp rules, in order that they may be adapted to the requirements of modern practice, as affecting bills of lading and charter parties;" "That the damage caused to machinery and boilers of stranded vessels in endeavouring to refloat be allowed in general average when shown to have arisen from actual intention to refloat the ship at the risk of such damage."

The Mersey Bar and Dock Accommodation.—Since the notable letter of Mr. Ismay to the Mersey Docks and Harbour Board, mentioned last week, Mr. Edmund Taylor has sent an equally strong letter endorsing the opinions raised by Mr. Ismay, and dwelling upon the necessity of providing a landing place capable of allowing the large steamers to go alongside at any state of the tide without entering the docks. In view of the deepening of the channel over the bar, which is shortly to be attempted, this landing place would confer enormous advantages on the American passengers, by doing away with the tedious and uncomfortable transfer from the steamer to the tender, and thence to the stage, to which they are now submitted.

SHEFFIELD, 14th May, 1890.

Iron and Steel.—Recent reductions in the prices of manufactured goods are leading to inquiries from consumers; evidently orders are waiting to be placed directly the prices come down. The Parkgate Iron and Steel Company, Ld., have now practically completed their extensive additions to plant. Local makers of rolling stock are complaining of the difficulty in obtaining sections of iron or mild steel suitable for the under frames of carriage or waggon stock. Railway material of all kinds is rather easier in value than for some time past. Locomotive tyres are quoted from £12 to £15, carriage and wagon tyres £10 to £12, and mild axles £11. Springs are quoted according to the amount of work in them, from £10 to £13. The Kilham Rolling Mills Company, Ld., who do general rolling of all kinds for the Sheffield trades, have issued their report for the past year, and announced a dividend of 5 per cent. against 2½ last year.

LEICESTER, 14th May, 1890.

Wool Spinning and Yarn Trades.—The condition of the wool market is on the whole unsatisfactory, though there is not much alteration since last report. Quotations are fairly firm, but generally there is a marked uneasiness in the market, and in some quarters there is a disposition towards a weakening. In this condition the consumers operate very cautiously. But even in these not very favourable conditions, the turnover in the aggregate is large, and, moreover, it is not speculative. New business in spinning is slow, as the users want lower prices and spinners try for an advance. Yarn merchants are moderately busy. Cashmeres are slightly weaker in price.

Boot and Shoe Trade.—Business continues remarkably active, and the difficulty experienced by manufacturers is to obtain sufficient labour. Overtime is being worked, and up till Whitsuntide there will be a very busy time. Leather merchants are doing a good, steady trade; the aggregate output is very large, and the sales effected are mostly for immediate use. Prices are steady, with no indications of any alteration.

SWANSEA, 14th May, 1890.

Tinplates.—The ready manner in which fifty-seven works—seven more than on the last occasion—have consented to stand idle for a second period of a week is a very convincing proof of the further difficulties that have recently beset the tinplate trade. The increased business that it was anticipated would follow the reduction in the price of bars has not been realised. Merchants appear willing to place orders at about 9d. per box below prevailing quotations, but makers insist that these are even yet too low, making new business a matter of impossibility. Although the nominal price of Bessemer tinplate bars is £5 10s. per ton,' some contracts have been entered into with north-country houses, whose agents have been diligently working this district, at £5 5s. per ton, with a liberal discount.

Wages of Riveters.—It was given in evidence during a recent trial under the Employers' Liability Act that a riveter employed by the Bute Shipbuilding Company has drawn an average of £3 15s. per week during the last three years, the amount never being less than £3. Day wages of riveters are 39s. per week.

Professor of Engineering.—The Council of the South Wales University College have resolved to advertise for a professor of mechanical engineering in the new engineering department, the stipend to be £300 per annum.

The Rhondda and Swansea Bay Railway.—The delay in opening the tunnel, due to the refusal of the Board of Trade Inspector to pass it as fit for passenger traffic, is a matter of less consequence than was at first supposed. The restraint does not extend to goods traffic, and the lining of the tunnel, which has been insisted on, will be the work of only a few weeks. Meanwhile, that part of the railway recently constructed between Cymmer and Blaengurynfy can be operated for passenger traffic. Three new levels are being opened at the London and South Wales Colliery at Blaenrhondda, which will give work to nearly a hundred additional hands.

CARDIFF, 14th May, 1890.

Iron and Steel.—There is a rather better tone noticeable in the pig iron market, and makers seem less inclined to stock. Prices are firmer all round, and unless the quotations are maintained several furnaces will be blown out. The Cwmavon Works, which were purchased by Messrs. Wright, Butler, & Co., Ld., last year, are about to be stopped, all the men having received notice. On the other hand, the Briton Ferry Ironworks will be set going next month. Steel tinplate bars are quoted nominally at £5 10s., but all depends upon the position of the makers as to whether they will accept this figure.

Coal and Coke.—The advance in wages, amounting to 13¾ per cent., accorded by the Sliding Scale Committee, came somewhat as a surprise to commercial circles generally. But, on consideration, the circumstance is not one that should cause much surprise, seeing that the contracts made at high figures are only now running out. For present business, however, the market looks very flat, and coal is realising far less than its value a few weeks ago. First quality steam sells at 14s. 6d. to 15s. 6d.; second, 13s. 9d. to 14s. 3d.; third, 12s. 6d. to 13s. 3d. Small steam coal is firm, notwithstanding the fact that makers of patent fuel are compelled to stop their works on account of unremunerative prices. Coke is fairly steady at 19s. to 20s. at ovens for furnace coke and 22s. to 24s. for foundry.

BARROW-IN-FURNESS, 14th May, 1890.

Hematite Iron.—The market is again quieter, and the general disposition of trade is anything but buoyant. Orders are small in number, and as they have for some time been chiefly confined to transactions in hematite warrants, some makers have at length come down in their prices. This they have been enabled to do by cheaper labour, cheaper iron ore, and cheaper coke; 7½ to 10 per cent. has been taken off the cost of labour, iron ore of ordinary quality has been reduced to from 10s. to 12s. per ton, and coke delivered from the East Coast has been reduced to 21s. per ton. Forty-seven furnaces are in blast, the number having been increased during the week by two furnaces, one at Carnforth and one at Cleator. The production of iron at Barrow, where there are thirteen out of fourteen furnaces in blast, is likely to be reduced next month by the blowing out of two furnaces. Stocks show a further reduction this week; 6,173 tons of hematite warrants have been cleared during the week, making a reduction since the beginning of the year of no less than 52,802 tons, but still leaving an aggregate of 327,840 tons.

Steel.—The steel trade is weaker. There is no activity in the demand in any of the departments, and the mills are only working five days per week. Rails are in fair but not brisk request, heavy sections being quoted at £5 per ton. Plates and angles for shipbuilding purposes are in quiet request at £7 5s. and £6 15s. respectively. Tinplate bars are quiet at £5 10s. per ton.

Shipbuilding and Engineering.—Although there are no immediate prospects of new orders in the shipbuilding and engineering trades, there are undoubted indications of the continuance of the present brisk trade, and of an improvement in both the erecting and the engineering departments.

Shipping.—The shipping returns still show marked activity. The exports of pig iron and steel during the week amounted to 23,553 tons, compared with 18,021 tons in the corresponding week of last year, an increase of 5,532 tons. The aggregate shipments this year represent 399,953 tons, compared with 392,041 tons during the same period in the previous year, an increase of 7,912 tons.

MIDDLESBROUGH, 14th May, 1890.

Pig Iron.—The Cleveland pig iron market is extremely flat, and there is very little business done. Merchants are asking 43s. per ton for prompt f.o.b. iron. Makers, too, have abandoned their reserve, and are competing for orders. Middlesbrough warrants can be obtained at from 41s. 9d. to 42s. cash. West Coast hematites are from 53s. 4½d. to 53s. 5½d. cash. East Coast hematites are nominally 60s., but can be had for less. The stock in Connal's store on Monday amounted to 126,243 tons, being 3,339 tons less than a week ago.

Shipments of Pig Iron.—These shipments have decreased at a time when they should have increased. Up till Monday the shipments for the month amount only to 24,548 tons, as against 34,902 tons to a similar date last month. Last year over a similar period they amounted to 35,078 tons. Germany and Holland maintain their demand, but other foreign countries have taken little more than half their usual quantity. Scotland, of course, still declines to buy on account of the difference between Scotch and Cleveland not being great enough. Wales also seems to be obtaining her iron more from Scotland than from Cleveland.
